In the present experiment it was thought best to follow Kingsbury's lead and investigate the influence of velocity on mean film thickness, and the apparatus was designed with this point in view. The bearing is shown in section in Fig. 1; it is non-adjustable and consists of a plain phosphor-bronze sleeve about 3¼ in. in diameter by 7 in. long, pressed into a cast-iron housing which was bolted to a lathe bed. Lubrication was effected by two steel oil rings of rectangular section. Two sets of oil grooves were cut in the upper half of the bronze as shown in the figure. On assembling the bronze sleeve and housing, it was found that the bronze was elliptical in section, with the major axis vertical, the average difference in diameters being 0.001 in. To obtain the best results from the apparatus, the sleeve should have been reamed after pressing it into the housing. Although this was not done, the inaccuracy did not seem to affect the results appreciably.

The journal was a piece of mild steel, ground carefully to a diameter of 3.244 in., giving a running-fit allowance of 0.0035 in., or about 0.001 in. per inch of diameter. On each end of the journal was fitted a cast-iron flywheel weighing about 67 lb., secured by a nut. The total weight of the assembled journal, flywheels and nuts was 165.5 lb., making a nominal load on the bearing of 7.275 lb. per sq. in. of projected area. The whole apparatus was mounted on two parallel lathe beds, and three lathe heads with four-step pulleys were utilized for the drive. The usual overhead countershaft drove the first lathe head, which drove the second head by a short piece of shaft and dogs. The second head drove the third by a short belt and tightener pulley. It was found necessary after several preliminary trials to introduce the tightener, so that the second belt could be used for gradual acceleration of the heavy rotating mass. The third head drove the test journal by a piece of ¼-in. steel shaft about 2 ft. long. As this flexible drive rod was loosely connected by a dog to the lathe head and by a cotter pin to the journal, it is fairly certain that no external deflecting load was applied to the latter. With the drive arranged in this way, sixteen speeds were possible, but as all the cone pulleys were of the same design, some of the speeds were duplicated, so that only six speeds could be used.

With this apparatus it would be possible to vary the bore allowance by starting with a very small allowance and then grinding down the journal to give larger allowances. This procedure was contemplated when the apparatus was designed, but lack of time prevented tests with more than one allowance. To locate the position of the journal with relation to the bearing, three micrometers of a design similar to Kingsbury's were used. The micrometers and journal were placed in the primary circuit of an induction coil with a battery, and a telephone receiver was connected to the secondary of the coil. With Kingsbury's apparatus it was only necessary to mount one micrometer in the bearing, because his bearing was a simple cast iron cylinder, so supported that it could be rotated about its own axis, thus bringing the micrometer into any position desired. His method was to locate the point of nearest approach and read the micrometer, calling this the zero reading. Then the bearing was rotated 180 deg. and another reading was taken. Half the difference between the zero reading and the second reading gave the radial distance between the axis of the bearing and the axis of the journal, and the angular displacement was read from graduations on the end of the bearing cylinder.

In the present experiment the bearing could not be rotated, so it was necessary to use three micrometers spaced 120 deg.

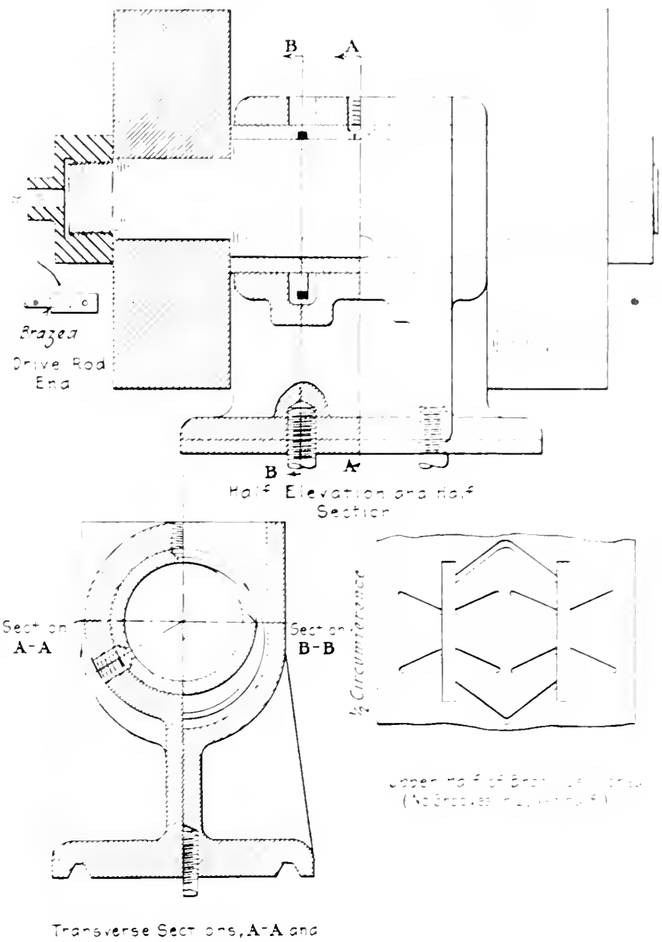

Fig. 1 Test Bearing

apart around the bearing in a plane through its center and perpendicular to its axis. The moving part of the micrometer consisted of a ¼-in. steel rod hardened at the contact end and threaded 40 threads per in. at the other end. To the threaded end was clamped a pointer 3¼ in. long which served both to turn the rod and to indicate the reading. The rod was carried in a brass sleeve threaded to receive it and electrically insulated from the bearing by a fiber bushing pressed on to the sleeve. The graduated scale was carried on an arm clamped to the top of the brass sleeve. This arm also carried a binding post for the electrical connection. The whole micrometer was held in place in the bearing by means of a brass collar which screwed down over the tapered fiber bushing.

[illegible] meters were calibrated by screwing them into [illegible] then screwing down the micrometer point to touch [illegible] inside micrometer. The experimental micrometers [illegible] graduated in this way to thousandths and the ten-thousandth divisions were laid off from these major divisions. Micrometers 1 and 3 were graduated for a total of [illegible] thousandths, and micrometer 2 was graduated over a range of six thousandths. Before any test readings could be taken, it was necessary to set the micrometers to zero, i. e., bring the micrometer points flush with the inside surface of the bearing brass by placing inside the bearing a sector cut from a polished iron ring which had been ground to the exact diameter of the bearing. The zero readings of all the micrometers were checked after every three or four test readings.

The runs were made short purposely, usually under two minutes, to eliminate the temperature factor as far as possible. A long run was made at a constant speed to obtain some information concerning the influence of temperature on the position of the journal relative to the bearing, but the micrometer readings showed that the bearing itself was expanding very rapidly due to its thin section, so this investigation had to be abandoned. From ten to fifteen readings of each of the micrometers were taken at each speed and the most consistent of the readings at each speed were averaged to obtain the final experimental data which are given in Table 1.

In determining the mean thickness of oil film from the results the following approximations were made: (*a*) that the loaded portion of the film was that below a horizontal plane through the center of the bearing, (*b*) that the thickness of the film at this plane and on each side of the journal was equal to the radial bearing allowance, (*c*) that the mean thickness of film was the average of the thickness at this plane and the minimum thickness of the film. The minimum thickness of film is the radial allowance minus the distance between the axes of the journal and bearing. Making use of these approximations the resulting values of mean thickness of film are given in Table 2.

The general equation of the curve plotted is

$$y = b + c^a \sqrt{V} \ldots\ldots\ldots\ldots\ldots\ldots [1]$$

where y = mean thickness of film in in.

b = one half the radial allowance

c = constant dependent on allowance and possibly on viscosity

a = constant dependent on viscosity and possibly on allowance

V = surface velocity of journal in ft. per min.

By translating the horizontal axis of the curve the constant b is eliminated and the equation becomes

$$y = c^a \sqrt{V} \ldots\ldots\ldots\ldots\ldots\ldots [2]$$

From the experimental curve the values of c and a were found to be

$$c = 0.0000049, \quad a = 1.8$$

and the resulting empirical equation is

$$y = 0.0000049^{1.8} \sqrt{V} \ldots\ldots\ldots\ldots\ldots [3]$$

As to the application of the empirical equation in the general equation for bearing lubrication, it may be said that it may be used directly for conditions of the same allowance and a lubricant having the same viscosity. For other allowances and lubricants the change of c and a cannot be stated definitely. It can be said in general that c will change with some function of the allowance and a with some function of the viscosity. It is also possible that c may be affected by the viscosity and a by the allowance.

The oil used during the experiment was an ordinary mineral oil, known as Vacoline, manufactured by the Standard Oil Company. Its viscosity as given by the Engler viscosimeter was 11.0 at 20 deg. cent. and 2.95 at 50 deg. cent. compared with water at 20 deg. cent., which gave a specific viscosity of 38.9 at 20 deg. cent. and 8.7 at 50 deg. cent.

INTERNAL-COMBUSTION ENGINES FOR SUGAR FACTORIES AND ESTATES

BY M. ADAM,[1] PINA, CAMAGUEY, CUBA

THE internal-combustion engine is making such rapid progress that it will be of interest to consider its possibilities in the cane-sugar industry. Naturally, with steam engines the exhaust steam can be utilized for the various heating and evaporating operations. At times, however, there is absolutely no use for exhaust steam, and, as generally no bagasse fuel is then available, oil, wood, or coal would have to be used for the steam plant, depending on the locality. The use of an oil engine here would at first sight seem possible, but calculation shows that the saving realized would not justify the expense of a new installation. Another point of importance in Louisiana sugar factories is that when the temperature is low, the heavy oil will not flow by gravity, and several devices which have been tried are either costly or inefficient. The best solution would be to use a pump run by an internal-combustion engine.

But the greatest field for liquid-fuel engines is on the agricultural side of the industry. The labor problem on the average sugar plantation is a source of anxiety and trouble; the problem of feeding and caring for the draught cattle is also a serious one, though the use of mules and horses is imperative. The amount of animal power required is only 30 per cent at present in the production of the cane, including harvesting. Machines are, however, being developed to do the

[1] Louisiana State University.

harvesting, and it can be safely predicted that in a few years the horse will only be required to do about 8 to 10 per cent of the total.

The agricultural motor tractor, although it has many advantages, has not come in as fast as was expected. The first motor tractors were of very heavy construction, with the consequence that the soil was packed and the crop injured. Of late years, however, the light tractor has made its appearance, and is now no longer an experiment. Some of the best types are the Mogul, Wyles, Martin, Ivel-Bauche, and the Sanderson. The type to be used depends largely on the nature of the soil. In the caterpillar type of tractor the area of contact between the ground and the engine is very much increased, thus securing a greater drawbar efficiency and lower pressure per sq. in. on the ground. A caterpillar 24 in. wide and with 6-ft. length of contact gives the same pressure as a road wheel with a 120-ft. diameter and a width of 24 in. The pressure per sq. in. of a caterpillar is only about 4 to 5 lb., which is very much less than the pressure exerted by the hoof of a horse. A caterpillar will also travel easily on almost any kind of soil, a point of importance. The Martin's cultivator, with its light and simple construction, is of this type; it is made to use benzol or gasoline, as most of the tractors of English make. The Mogul type, however, can burn kerosene, which is so much cheaper than gasoline. Another possible application of heavy-oil engines in sugar plantations is for irrigation, and in some countries for drainage.

The heavy-oil engine has a decided advantage over other types also in fuel cost. The cost per b. hp-hr., excluding rent, administrative costs and electrical apparatus, works out from careful calculations, as follows:

Steam plant	1.605 cents
Gas-producer plant	1.222 cents
Heavy-oil-engine plant	0.511 cent

Gasoline plant was not included, as the cost would undoubtedly come even higher than that for steam plant, and it is safe to assume that an alcohol engine could not compete with the heavy-oil engine or the gas-producer plant. When we speak of heavy-oil engines, we have in mind the Diesel engine. This engine differs from all other internal-combustion engines in that a full charge of air is compressed to a point above the igniting point of the fuel and the fuel injected into it, when it burns under a pressure and temperature which can be perfectly controlled. There are no explosions, but a steady combustion at a predetermined lower temperature and without any increase in pressure, the combustion line being practically an isothermal. A small pump supplies the fuel to the chamber. A special compressor serves to compress the air to inject the fuel and to store a surplus in an air tank for starting the engine when cold. A very sensitive governor controls the quantity of fuel injected, regulating the heat, and hence also the expansive power of the air medium. Apart from high efficiency, a great advantage with this type of engine is that there is practically no limitations as to the kind of fuel to be used, so long as it is liquid.

In installing an irrigation plant for a large sugar plantation, the best arrangement would be to have a central plant near the sugar factory, delivering current at say 440 volts. This can be stepped up to 12,000 volts at the plant and distributed over the plantation, being stepped down again to 440 volts to each separate motor directly connected to its pump. It would be well to divide the power required between a steam plant and a Diesel plant. During grinding, most of the load would be taken by the steam generator, thus permitting the utilization of the exhaust steam. By partially electrifying, say, the centrifugals and machine shop for manufacture of sugars and repair work could be done most efficiently, the load being then taken by the Diesel engines, as there will then be no use for exhaust.

To my knowledge there are no such plants in existence, though there are several using producer gas. The great Buzi Illovo estates in Portuguese East Africa are irrigated in this manner. Most of the property consists of flat alluvial soil, the water being pumped from the Buzi River by means of seven centrifugal pumps, three of which are operated by a suction plant. There is also another producer-gas irrigation plant in the tropics which is giving perfect satisfaction. It consists of three gas producers and three gas engines directly connected to electric generators. There is also one water-tube boiler and a 800-hp. poppet-valve engine directly connected to a 600-kw. generator. Eleven pumps geared and belted to 50-cycle, 310-volt motors, furnishing water for the irrigation of the sugar cane, are located on the different haciendas. The gas plant consists of three double-acting, two-cylinder, four cycle, 18 x 24-in. Allis-Chalmers gas engines running at 200 r.p.m. The engines are supplied with gas by three R. D. Wood dry-bottom, updraft producers, which may be worked as suction or pressure, burning anthracite coal.

All the electric generators, directly connected to engines, are of 200 kw. capacity, and deliver 50-cycle current at 310 volts, which is stepped up to 15,000 volts at the power house. At the pumps the current is stepped down to 310 volts. The irrigating pumps are at a distance of ½ mile to 4 miles, respectively, from the power house; the main plant is located near the factory. The gas plant is operated all the year for irrigation and takes off the factory load on clean-up days and days when there is no demand for exhaust steam. Tests run on the gas-producer plant gave 1.742 lb. of coal per kw-hr. and 1.387 lb. of coal per b. hp-hr., which shows very high efficiency.

With a plant of this size, however, the Diesel engine would give more economical service, and the day will probably come when this type of engine will be universally used for such work as irrigation and drainage.

Since its use was brought to the notice of the world in 1830, the export of nitrate of soda from Chile has exceeded a total of 53,000,000 long tons, and the present output is in the neighborhood of 2,500,000 to 3,000,000 long tons per annum. It is safe to estimate that the known areas can provide nitrate of soda for another 200 years at the present rate of production.—*Metallurgical and Chemical Engineering*, Mar. 1, 1917.

"It has often been said that the fixation of atmospheric nitrogen is not practicable in the United States because of the high cost of power. Now nitrate of soda costs $[illegible] per ton in New York, which is equivalent to $95 per ton for pure nitric acid. In Norway and elsewhere it requires about [illegible] kw.-year to produce a ton of nitric acid. The Mississippi River Power Co. supplies power to St. Louis at $[illegible] per kw.-year at 60 per cent load factor. At this rate the power necessary to produce a ton of acid would cost about $[illegible], and the margin between this and $95 is sufficient to warrant a very careful inquiry before accepting the statement that it cannot be done."—Charles W. Comstock, in Proc. A.I.E.E., January, 1917.

I am indebted to Prof. Kerr for this information.

WORK OF THE BOILER CODE COMMITTEE

THE Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York City.

The procedure of the Committee in handling the cases is as follows: All inquiries must be in written form before they are accepted for consideration. Copies are sent by the Secretary of the Committee to all of the members of the Committee. The interpretation, in the form of a reply, is then prepared by the Committee and passed upon at a regular meeting of the Committee. This interpretation is later submitted to the Council of the Society for approval, after which it is issued to the inquirer and simultaneously published in The Journal, in order that any one interested may readily secure the latest information concerning the interpretation.

Below are given the interpretations of the Committee as approved by the Council on March 16, 1917, in Cases No. 140 and 143. In this report, as previously, the names of inquirers have been omitted.

Case No. 140

Inquiry: Do small vertical tubular boilers built for operation in connection with laundry or clothes pressing machinery and which are less than 24 in. in diameter, necessarily come under the requirements of Par. 266?

Reply: The Committee has decided that all boilers 24 in. or less in diameter shall have at least one opening for inspection and one opening in addition to the blow-off for washing out the boiler, these openings to be fitted with brass plugs.

Case No. 143

Inquiry: Has any action been taken as yet by the Boiler Code Committee in the matter of eliminating the copper content requirement for firebox boiler plate steel in Par. 25? Great difficulty is now experienced in securing plate to meet the present requirements of this paragraph.

Reply: The copper content requirement has been eliminated.

The National Research Council has organized an investigation on the subject of Food Poisoning, to be undertaken by the Harvard Medical School in its department of preventive medicine and hygiene.

The American Association for the Advancement of Science and many national scientific societies affiliated with it will hold its 70th meeting in Pittsburgh from December 28, 1917 to January 2, 1918, under the auspices of the University of Pittsburgh, the Carnegie Institute, Carnegie Technical Schools and other scientific and educational institutions of the city.

As already published in The Journal, Congress appropriated last fall \$35,000 to a monument in memory of John Ericsson, the eminent engineer, who was also a member of The American Society of Mechanical Engineers. This monument is to be erected in a prominent place in Washington. A special Commission was appointed by the Government, known as the John Ericsson Monument Commission, to take care of the details in connection with the erection of the monument. As mentioned in The Journal for March, 1917, six of the members of The Society are members of this Commission, which met at Chicago, March 10. It was the unanimous opinion that the sum appropriated by Congress would not be sufficient to erect a fitting memorial to a great engineer which would compare favorably with the memorials erected to men of other professions, and it was decided that at least \$25,000 ought to be added to the appropriation made by the Government, in order that a fitting memorial might be erected. It is proposed to raise this amount by private subscription, and all American engineers, organizations, and societies are invited to aid in commemorating the memory of John Ericsson, who gave signal service to the country at a time when its very existence hung in the balance. It is the first time that the United States Government has made an appropriation for the erection of a monument to an engineer, and as this engineer was also a member of The American Society of Mechanical Engineers, it is hoped that the members of the Society will be proud in aiding the efforts of the John Ericsson Monument Commission. Subscriptions toward the monument will be received by Erik Oberg, Associate Editor of *Machinery*, 148 Lafayette St., New York, a member of The American Society of Mechanical Engineers, who is also a member of the Commission. Subscriptions thus received will be acknowledged by publication as directed by the Commission.

The Engineers' Society of Western Pennsylvania took steps at a recent meeting to create a suitable memorial to the late George Westinghouse, Past President and Hon.Mem.Am.Soc. M.E. The meeting bore testimony that he was a persistent and indefatigable worker upon problems involving the safety and comfort of mankind, and that as an inventor and engineer he was the most widely and favorably known man of his time.

The following resolution was passed unanimously: "Resolved, that this Society, through its President, appoint a committee of five members, to be known as the Westinghouse Memorial Committee, who shall investigate a plan for the purchase of the former home of Mr. Westinghouse, known as Solitude, consisting of ten acres of land, converting same into a public park, to be forever known as 'Westinghouse Park,' erecting thereon a suitable memorial, and turning the whole over to the city of Pittsburgh, under its guarantee that the gift shall receive the same care and protection as other parks owned by the city."

The committee appointed consists of George S. Davison, Julian Kennedy, Vice-Pres.Am.Soc.M.E., William L. Scaife, Charles F. Scott, Mem.Am.Soc.M.E., and E. B. Taylor.

Members of the Society will wish to associate themselves with their colleagues of the Pittsburgh fraternity in doing honor to a distinguished citizen and engineer, and an honorary member of the Society, and hope that their efforts will be rewarded by an early realization of the memorial proposed.

SOCIETY AFFAIRS

A Record of the Current Activities of the Society, its Members, Council, Committees, Sections and Student Branches; and an Account of Professional Affairs of Interest to the Membership

PRESIDENT HOLLIS is now on his second tour, covering this month the cities of Philadelphia, Pa., Schenectady, N. Y., Troy, N. Y., Buffalo, N. Y., Minneapolis, Minn., Indianapolis, Ind., Columbus, O., and Pittsburgh, Pa.

The message which Dr. Hollis is delivering to enthusiastic audiences was never more timely than now. The purport of it is that:

> We engineers can only take one attitude, that every citizen is permitted, even expected, to develop himself to the highest degree of service for his nation and mankind. There is only one way to do this, and it is for us to unite in the kind of good-will and good-fellowship that will enable us to work together towards the glory of our country—in peace, we hope, but in war if it is absolutely necessary.

The movement for this started throughout the world even before the present war, but of course the war has accentuated it both in this country and abroad.

The membership of the Society has recently received two circulars from the Engineering Societies' Joint Committee on Reserve Corps of Engineers; as a result about 1500 applications for commissions in the Engineer Officers' Reserve have been filed with the War Department. Perhaps one-third of these have been issued by the Secretary of War and signed by the President of the United States.

At the request of President Hollis, the presidents of the engineering societies have had two conferences with representatives of the National Council of Defense and of the Army and the Navy, with the result that there is in preparation a letter telling about the several departments of the service in which an engineer may enroll in the Officers' Reserve. In some of these departments the full complement has already been obtained, but in some others there is still a great need of reserve officers, particularly for members of this Society, experienced as they are in manufacture and in handling men.

Elsewhere in this issue is a resumé of the account of the opening and the dedication of the Science Building given by Past-President Swasey to Nankin University.

Letters have been received from both Dr. Brashear and Mr. Swasey telling of their wonderful trip to the Orient with Mr. Freeman and his two sons. The party is due to sail from Honolulu on the Tenyo Maru on March 27, reaching San Francisco April 2. Dr. Brashear states that when he boarded the boat at Vancouver 225 letters were awaiting him, and that in order to answer them all he has written ten articles for the Pittsburgh newspapers!

While on tour, Dr. Brashear gave two lectures in Peking, two at Shanghai, two at Canton, one at Manila and two on the ships on which he has been traveling. He has also promised our Committee on Meetings an address at the next annual meeting of the Society.

In one audience of his in Canton there were 1200 Chinamen and women, besides foreigners. In many cases his lectures had to be interpreted, interpreters being often Yale graduates to whom he kindly enough gave credit for delivering his lectures better than he himself did.

The party has met President Li Yuan-heng, the Vice-President, the President of the Senate and others of China's most brilliant men, both in politics, business and education. Mr. Freeman, in a conversation with the President of the Chinese Republic, emphasized the necessity for conservation in China particularly with respect to waterways.

Mr. Swasey is held in the highest esteem in China, where he has done wonderfully good work, both in the educational institutions and in the Y. M. C. A. During the trip, Mr. Swasey's seventieth anniversary was celebrated by a dinner given by Mr. Freeman.

The alumni of the Massachusetts Institute of Technology in Shanghai gave a dinner to Mr. Freeman and his sons also; in fact, the social entertainments were most complete wherever our friends visited.

This trip of our distinguished past-presidents calls to mind that we engineers, in our professional work and in our vacation trips, go all over the world. We thus have excellent opportunities for extending the greetings of the Society and developing the professional spirit universally. Please, therefore, invite engineers and officers of professional societies to call and send their friends to the Society headquarters, and we will do our best to assist them in whatever errand they may have.

Calvin W. Rice,
Secretary.

Council Notes[1]

AT the meeting of the Council on February 16, the following members were present: Ira N. Hollis, *President*, presiding; John H. Barr, C. H. Benjamin, R. H. Fernald, W. B. Gregory, W. B. Jackson, D. S. Jacobus, Charles T. Main, Spencer Miller; Wm. H. Wiley, *Treasurer;* R. M. Dixon, *Chairman Finance Committee*, and Calvin W. Rice, *Secretary*.

Representation at Council Meetings. It was voted to add the chairman of the Sections Committee to those committee chairmen now receiving invitations to attend Council meetings and take part in the discussion of matters relating to their work. The chairmen of the Finance, Meetings and Publication Committees already receive such invitations.

Increase of Membership Committees. A. G. Kessler was appointed chairman of an Increase of Membership Committee for Erie and vicinity, and Charles T. Hutchinson of a similar Committee for San Francisco and vicinity.

A.S.M.E. Boiler Code. Interpretations Nos. 76, and 116 to 135 inclusive, of the Boiler Code Committee were approved as presented, with one exception, No. 125, which was slightly amended, and ordered published. They appear in the March issue of The Journal.

A request from the Compressed Air Society that the Boiler Code Committee consider the formulation of rules to cover pressure vessels other than steam was referred back with the

[1] The March Journal went to press before the February meeting

request that the Society submit a brief covering the modifications of the Boiler Code it would recommend to meet the case.

Sections. Ernest Lee Jahncke was appointed on the executive committee of the New Orleans Section, in place of A. L. Black, resigned.

Student Branches were approved at Johns Hopkins University, University of Washington and University of Pittsburgh. The total number of Branches is now forty-three.

Engineering Standards Committee. In response to an invitation from the American Institute of Electrical Engineers for appointment of three representatives on a proposed joint conference committee of the national engineering societies, on a committee to bring about coöperation in American Engineering Standards, our Standing Committee on Standardization was authorized to appoint three of its members as the representatives of our Society on the joint committee.

Naval Consulting Board. Mr. Spencer Miller, one of the Society's two representatives on the Naval Consulting Board, reported the appointment of a Sub-committee on Special Problems, and that the Board is now holding frequent meetings, the proceedings of which are being kept confidential for obvious reasons.

Society Representation. Mr. Spencer Miller was appointed to represent the Society at the annual meeting of the American Institute of Mining Engineers.

Prof. H. E. Satterfield was appointed to represent the Society at the inauguration of Professor Ruddick as President of the North Carolina College of Agriculture and Mechanical Arts, on February 22.

Exchanges of Courtesies. It was voted to accept with appreciation and to most cordially reciprocate the exchange of courtesies to members in the use of the Library and rooms with the Institution of Civil Engineers, of England, and the Engineers Society of Northeastern Pennsylvania.

Calvin W. Rice,
Secretary.

United Engineering Society

Extracts from President's Annual Report

The important fact of the year 1916 in the United Engineering Society is that on July 25 contracts were executed by which the American Society of Civil Engineers became an additional Founder Society and arranged to make its permanent home in the Engineering Societies Building. The contracts provide for the construction of three additional stories to the building, the American Society of Civil Engineers to contribute a sum considered equivalent to what each other Founder Society had contributed and to participate in the original Carnegie gift and have an equal share in the property with each other Founder Society.

The construction of the addition to the building is under way, \$62,525.04 having been expended thereon in 1916. This work is in charge of a Building Committee consisting of H. H. Barnes, Jr., Chairman, E. G. Spilsbury, Charles Warren Hunt and Charles F. Rand.

At the request of the Founder Societies, important alterations were made to the lecture halls on the fifth floor of the building to make them suitable for social functions of the societies.

The Library of the American Society of Civil Engineers is being merged with the Library of the United Engineering Society and the Founder Societies.

At the present time the membership of the four Founder Societies is 29,000, and of associate societies 23,000, so that a total of 52,000 engineers now have their headquarters in our building.

The building is at present fully occupied.

The value of the real estate now owned by the United Engineering Society is \$1,617,171.16. This sum will be increased at the end of 1917 by the amount of the cost of the addition to the building.

The income of the Society during 1916 was..	\$53,062.03
The expenditure was....................	44,316.20
Gain for the year........................	\$8,745.83

Funds for the benefit of the Library were obtained during the year from contributions by the societies of Civil, Mining, Mechanical and Electrical Engineers and the United Engineering Society to the amount of................. \$15,542.33

From miscellaneous sources................	1,751.03
The gross income from searches was.........	5,382.98
Total............................	\$22,676.34

The Library expenses have been as follows:

Library Books purchased..................	\$2,340.88
Library Binding Expense..................	1,442.55
Library Supplies and Miscellaneous Expense.	1,379.38
Library Salaries..........................	10,923.81
Library Photostat.........................	1,091.02
Library New Lighting Fixtures.............	132.47
Library Searches Expense..................	5,366.23
Total............................	\$22,676.34

Dr. James Douglas, who started our Library Endowment Fund with a gift of \$5,000, has added \$95,000 thereto. The total of the fund is now \$102,559.70. An effort is being made to materially increase this fund, as the Library requires the income of a million dollars for its proposed development.

The securities in the Engineering Foundation Fund were sold and the proceeds reinvested to produce a higher income, as shown in detail in the Treasurer's report. The Fund now amounts to \$203,374.80.

The General Reserve Fund remains unchanged at..................................	\$10,000.00
The Depreciation and Renewal Fund is now..	71,456.12
The Surplus Account December 31, 1916, is..	6,053.25

Charles F. Rand,
President, United Engineering Society.

Professor Carpenter to Retire

Prof. R. C. Carpenter, Past Vice-President Am.Soc.M.E., reaches the retiring age at the end of the present college year and will sever his active connection with Cornell University at that time.

Respecting his retirement, the Committee on General Administration of the Board of Trustees adopted the following resolution:

> Resolved, that the Trustees in accepting the resignation of Professor Carpenter express their high appreciation of his services to the University for nearly thirty years. As a pioneer in the field of experimental engineering he is held in the highest esteem by all mechanical engineers, and by his writings in this field he has made an assured place for himself in the annals of his profession. As a teacher and investigator he is affectionately remembered by many generations of students, and his retirement from the Faculty of Sibley College will be viewed with great regret by all his colleagues.

THE SPRING MEETING AT CINCINNATI

THE fundamental principles which the engineers of this country have found to be essential for the successful production of munitions will form the subject of an important sion of the Spring Meeting of The American Society of Mechanical Engineers, to be held in Cincinnati, Ohio, May 21 to 24. A year ago, when the country began to take up the question of Industrial Preparedness, the Society devoted a session of its Spring Meeting in New Orleans to a discussion of this subject. This discussion was the means of bringing out many valuable ideas—one of them that of an industrial inventory, which was later put into effect by the Committee on Industrial Preparedness of the Naval Consulting Board. As the result of this inventory, the Government now has on file important data regarding the capabilities of nearly 30,000 industrial concerns in this country to manufacture munitions in case of necessity. It is expected that the Munitions Session at the coming Spring Meeting in Cincinnati will bring out a large amount of first-hand experience in munitions manufacture from firms which have specialized in this business during the last two years. Such information will afford a valuable supplement to that contained in the Industrial Census.

The meeting is in charge of the Committee on Meetings and the Cincinnati Section Committee, and other professional features will be a Session on High-Speed Gasoline Engines, at which recent developments in connection with internal-combustion engines for automobile and aviation service will be presented; a Session on Machine Shop Practice, devoted to questions relating to design and construction of machine tools, and a Joint Session with the National Machine Tool Builders' Association, which as attested by the following letter from John T. Faig, chairman of the Cincinnati Section, will be an important event for both societies. Incidentally, Mr. Faig's letter discloses some of the good things in store for those who attend the meeting.

THE SECRETARY, THE AMERICAN SOCIETY
OF MECHANICAL ENGINEERS:

The outstanding feature of the Spring Meeting for 1917 is the fact that it will occur at the same time and place as the meeting of the National Machine Tool Builders' Association, and that one of the professional sessions and several of the entertainment features will be joint sessions. This will bring our own Society in closer touch with machine-tool building. The building of all forms of heat motors, or water wheels, of railway apparatus, of heating and ventilating devices, and of transmission machinery, seems to be recognized as belonging more clearly to the field of the mechanical engineer than does machine-tool building. This is probably due to the fact that early machine tools were largely empirical, that very little was known regarding the laws underlying the cutting of metals and the power required to remove material by means of cutting tools. Improvements in various cutting steels and more rigid demands made upon machine tools by the general introduction of interchangeable parts, have caused an extremely rapid development in the machine-tool industry, which is fast raising machine-tool building to a science.

It is natural that special emphasis should be placed on machine-tool building at the Cincinnati meeting, for the reason that an amazing development of the machine-tool industry has occurred there during the past thirty years—a development apparently out of all proportion to that which has occurred in other lines in mechanical engineering.

It seems particularly fitting, therefore, that the American Society of Mechanical Engineers and the National Machine Tool Builders' Association should meet together at Cincinnati, and that these two organizations, already closely related, should come into more intimate contact. The local session, which is to be devoted to industrial education and to welfare work, will be a joint session of these two societies and of equal interest to both. Inspection trips to the various shops will be of interest to both societies.

A word about the entertainment features will not be out of place. The Entertainment Committee is making strong efforts to provide some novel and very attractive features that will maintain the reputation made when the British Institute of Mechanical Engineers visited Cincinnati in 1904. May is usually a lovely month in Cincinnati, and the topographical features of the Queen City make it attractive to those who enjoy being out of doors in the early Spring. A number of very beautiful spots are to be visited on the automobile ride, which is scheduled for Thursday afternoon. Arrangements have been made to afford visiting members, who desire to relax, an opportunity to play golf at one of the country clubs. For those who have the latter part of the week to spend, delightful trips may be made to the famous mound

SKY LINE, CINCINNATI, OHIO

Art Museum and Art Academy, Cincinnati

known as Fort Ancient, at Morrow, Ohio, about forty miles away; to the famous Blue Grass Region of which Lexington, Kentucky, is the center, which is a veritable garden in May, and to the world-famous Mammoth Cave in Kentucky.

Beside visits to the well-known machine-tool and steam-engineering firms, a number of invitations from large concerns making steel, soap, pianos, and other commodities have been received, so that a visiting member will have a wide choice in his selection of places to visit.

In general, the practice of the Society of holding professional sessions in the mornings and devoting the afternoons to entertainment and visits will be followed, except that on Tuesday afternoon there will occur a special professional session, which will be the joint session already mentioned.

Cincinnati is well supplied with hotels of every class. As May is a busy month, however, and as Cincinnati is rather popular as a convention city, members who expect to attend the meeting are urged to make reservations at once.

John T. Faig,
Secretary, Cincinnati Section.

Information regarding transportation to Cincinnati, hotels, the program of the meeting, features of interest to be inspected, entertainment, etc., is given below, and will be followed in the next issue by the complete program giving titles of the papers to be presented and discussed at the professional sessions. In the next issue, also, will be published comprehensive abstracts of these papers, and as heretofore the papers will in addition be published in pamphlet form in advance of the meeting and may be obtained by members upon application, for the purpose of contributing discussion.

TRANSPORTATION AND FARES

The Committee on Meetings, in order to secure as large a benefit as might be derived from selecting a particular train for those of our party attending this meeting from the East, have designated the train leaving New York City by the Pennsylvania Railroad at 5.30 p.m. on Sunday evening, May 20, as the official train. The schedule of this train follows:

New York to Cincinnati

	Train No. 7.
Lv. New York City, Pennsylvania Station	5:30 P. M.
Manhattan Transfer	5:48 P. M.
Newark, Market Street	5:52 P. M.
Trenton	7:00 P. M.
Philadelphia, North	7:38 P. M.
Philadelphia, West	8:07 P. M
Philadelphia, Broad Street	8:03 P. M.
Atlantic City	4:45 P. M.
Baltimore	8:05 P. M.
Washington	7:00 P. M.
Harrisburg	10:45 P. M.
Altoona	1:38 A. M.
Ar. Pittsburgh, Eastern time	4:30 P. M.
Lv. Pittsburgh, Central Time	3:55 A. M.
Ar. Columbus	8:45 A. M.
Ar. Cincinnati, Central time	12:20 P. M.

The individual rate, New York to Cincinnati, is $18.68; the party fare, ten or more traveling together on one date and train, is $16.42. The same rates apply in the reverse direction.

There is an extra fare on the train above mentioned, between New York and Cincinnati, of $1.00.

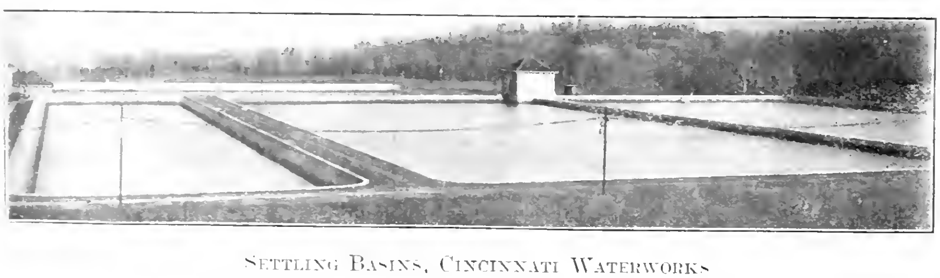
The lower berth rate, New York to Cincinnati, is $4; upper,

Ohio River from Eden Park

$3.20; compartment, $11.50; drawing room, $14. The same rates apply in the reverse direction. A minimum of one and a half tickets are required for compartment space and two full tickets for drawing room.

All reservations for this train should be made with William V. Kibbe, District Passenger Solicitor, Pennsylvania Railroad, 487 Fifth Avenue, New York City.

Members residing in the New England States who do not wish to come by way of New York and join the party on this train, may find it convenient to take the New York Central train which leaves Boston at 2:00 p.m. Sunday, May 20, arriving in Albany at 7:45 p.m. This train leaves New York



Settling Basins, Cincinnati Waterworks

at 4:50 p. m. on Sunday and arrives in Cincinnati at 11:15 on Monday morning.

HOTELS

The Cincinnati Section Committee has selected the Hotel Sinton as headquarters for the Spring Meeting. The rates of this hotel are as given below, and members are requested to *write direct to the hotel for reservations*. Some members

Bird Cages at Zoo

may prefer to stay at the Hotel Gibson, diagonally across the street from the Sinton, or elsewhere, in which case the following table of rates will be of service to them. The rates are on the European plan.

Hotel Sinton

Room without bath, one person	\$1.50 per day and up
Room with bath, one person	2.00 per day and up
Room without bath, two persons	2.50 per day and up
Room with bath, two persons	3.00 per day and up

Hotel Gibson

Room with bath, one person	\$2.00 per day and up
Room with bath, two persons	4.00 per day and up

Grand Hotel

Room without bath, one person	\$1.00 per day and up
Room with bath, one person	2.00 per day and up
Room without bath, two persons	2.00 per day and up
Room with bath, two persons	3.50 per day and up

Rookwood Pottery, Cincinnati

TENTATIVE PROGRAM

With the meeting still six weeks off, the Meetings Committee and the Cincinnati Section Committee have practically completed the details of the program. There remain but one or two special sessions to be inserted. A slight change in the arrangements for excursions has been made over those given in the last issue of the Journal.

Monday, May 21

Morning........Registration.
Afternoon.......Registration.
Trip to hospital.
Visits to shops in Cincinnati.
Evening........Informal gathering.
Address of welcome.
Dancing.

Tuesday, May 22

Morning.........Business Meeting.
Machine Shop Session.
Visit by ladies to Rookwood Pottery and Art Museum.
Afternoon.......Joint Session with National Machine Tool Builders' Association.
Visits to shops in Cincinnati.
Trolley ride by ladies to Fort Thomas.

Municipal Hospital, Cincinnati

Evening	Smoker for gentlemen
	Reception for ladies

Wednesday, May 23

Morning	Munitions Session, as the [illegible] day or else adjourning to Thursday morning
	Trip for ladies through leading stores and skyscraper
Afternoon	Boat ride for all to Fernbank Dam or Water works
Evening	Informal dance

Thursday, May 24

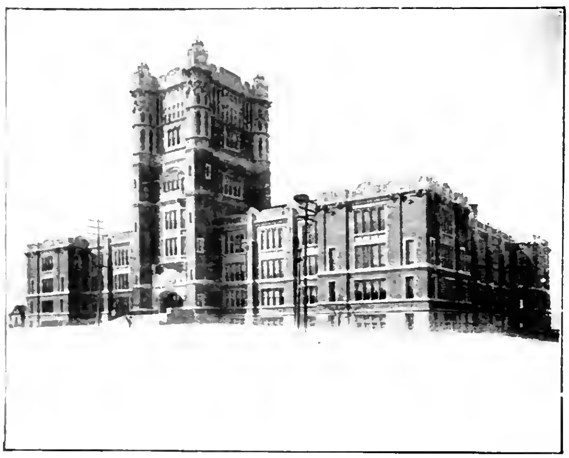
Morning.......	Miscellaneous Session.
	Gasoline Engine Session.
	Trolley ride for ladies to the Zoo.
Afternoon......	Visits to machine plants.
	Motor-car ride to Mt. Storm, University of Cincinnati, Observatory and Ault Park.

Friday, May 25

Morning........	Trip to Fort Ancient (Extra).
	Trip to Mammoth Cave, Ky. (Extra).
	Trip to Lexington, Ky. (Extra).

TECHNICAL EXCURSIONS

Among the technical features of the entertainment at the Spring Meeting will be a visit to the large new station of the Union Gas and Electric Co., which is really of metropolitan dimensions; a visit to the Waterworks System, and a visit to the Fernbank Dam. The dam in the Ohio River, at the western city limits, is said to be the largest movable dam in the world. It is one of a series of 54 locks and dams being built by the Government in this river to make it navigable from Pittsburgh to Cairo.



Hughes High School, Cincinnati

Visits will also be made to some of the great machine tool factories in and near Cincinnati, and also to such great industrial concerns as the Procter and Gamble Soap Company.

PLACES OF INTEREST

Besides the engineering features of Cincinnati, those attending at the Spring Meeting will find many places of particular interest to visit.

The famous Rookwood Pottery is located on the brow of Mt. Adams, overlooking the downtown section of the city. Here the beautiful Rookwood ware is produced.

The Cincinnati University, in Burnet Woods, comprises McMicken, Cunningham, and Hanna Halls, the Van Wormer Library, Engineering Hall, Chemistry Building, Gymnasium, Power Plant and Observatory, which latter is on Mount Lookout, six miles from the center of the city. It is the only municipal university in the United States.

The Ohio Mechanics' Institute is another great educational institution. It is now housed in a magnificent new structure at Walnut, Canal and Clay Streets, which accommodates 4,000 students, and is a big factor among scientific and industrial training schools.

Cincinnati has a city hall which cost $2,000,000, and three new high schools which in architecture and appointments are not excelled in any city in the United States. The government building and custom house on Fifth Avenue cost over $6,000,000. A new municipal hospital cost $4,000,000.

Cincinnati has a system of public parks and boulevards which covers about 2,500 acres, and is now undergoing extensions and improvements. The oldest is Eden Park, located on the crest of Mt. Adams; it was once the vineyard of Nicholas Longworth, great-grandfather of Congressman Longworth.

Among points easily reached from Cincinnati are Chattanooga, Tenn., with the battlefields of Lookout Mountain, Signal Mountain and Missionary Ridge; Boonesborough, Ky., the oldest settlement established by English-speaking people in the Mississippi Valley; Lincoln's birthplace, near Hodgenville, Ky.; Mammoth Cave and Colossal Cavern; the tomb of President Harrison at North Bend; Point Pleasant, the home and birthplace of Ulysses S. Grant, and Georgetown, where the great General spent his boyhood.

Junior and Student Prizes

In the Technical Section of this issue are included papers by Howard E. Stevens, Boynton M. Green and M. Adam, which were awarded Student prizes at the Annual Meeting of the Society, December 1916.

It is hoped that these examples may stimulate those of our Junior Members and members of Student Branches who intend to enter for this year's competition, which closes on June 30, 1917, and particulars of which were published on page 153 of the February issue of The Journal and are also given in the 1917 Year Book on pages 508-9.

Any further information regarding this competition will be furnished on application to the Secretary, who will also be glad to give any suggestions to those entering this year.

Colonel Walter Katte

Col. Walter Katte, who was for fifty years active in railroad and bridge construction in this country, died in New York City on March 5. He was the first chief engineer of the Second and Ninth Avenue Elevated Railroads of the metropolis, and was identified prominently with the construction of the West Shore Railroad. His railroad experience included ten years in the service of the Pennsylvania System and twelve years as chief engineer of the New York Central Railroad. He was one of the early members of the American Society of Civil Engineers, and served twice as a director of the Institution of Civil Engineers, of London.

Mr. Katte's son, E. B. Katte, is a past Vice-President of our Society.

CANDIDATES FOR MEMBERSHIP

TO BE VOTED ON AFTER MAY 10, 1917

THE American Society of Mechanical Engineers is an organization for mutual service of over 7800 engineers and associates coöperating with engineers. The membership of the Society comprises Honorary Members, Members, Associates, Associate-Members and Juniors, all elected by ballot of the Council. Application for membership is made on a regular form furnished by the Secretary which provides for a statement of the standing and professional experience of the applicant and requires references from voting members personally acquainted with the applicant. The requirements for admission to the various grades will be furnished upon request.

Below is the list of candidates who have filed applications for membership since the date of the last issue of The Journal. These are classified according to the grades for which their ages qualify them, and not with regard to professional qualifications, i.e., the ages of those under the first heading place them under either Member, Associate or Associate Member, those in the next class under Associate-Member or Junior, and those in the third under Junior grade only. Applications for change of grading are also posted.

The Membership Committee, and in turn the Council, urge the members to scrutinize this list with care and advise the Secretary promptly of any objections to the candidates posted. All correspondence in this regard is strictly confidential. Unless objection is made to any of the candidates by May 10, 1917, and providing satisfactory replies have been received from the required number of references, they will be balloted upon by the Council. Those elected will be notified about June 15, 1917.

NEW APPLICATIONS

FOR CONSIDERATION AS MEMBER, ASSOCIATE OR ASSOCIATE-MEMBER

California

ABBEY, ALFRED R., Construction Engineer, Standard Oil Co. of Cal., Whittier

COX, SPENCER F., Mechanic, A. T. & S. F. R. R., San Bernardino

OTTERSON, N. E., Sales Manager, Senn Concentrator Co., San Francisco

Connecticut

BRYANT, RAYMOND F., Assistant to Vice-Pres., and Gen. Supt., Yale & Towne Mfg. Co., Stamford

HUBBARD, FRANKLIN G., Vice-President, The H. E. Harris Engrg. Co., Bridgeport

METZGER, ELMER E., General Superintendent, Geometric Tool Co., New Haven

STARR, ADOLPH, Chief Gage Inspector, Winchester Repeating Arms Co., New Haven

UNGAR, G. A., Technical Manager and Chief Engineer, S.K.F. Ball Bearing Co., Hartford

Delaware

HOMEWOOD, WILLIAM T., Designing Engineer, E. I. du Pont de Nemours & Co., Wilmington

PIERCE, H. M., Chief Engineer, E. I. du Pont de Nemours & Co., Wilmington

Illinois

BLAINE, JOSEPH R., Mechanical Engineer and Designer, Miehle Printing Press & Mfg. Co., Chicago

CALAME, ARMAND, Assistant Foreman Machine Shop, Elgin National Watch Co., Elgin

MILLER, KAY C., Chief Tool Designer, Chief Inspector, The Root & Van Dervoort Engrg. Co., E. Moline

WEBSTER, TOWNER K. JR., Vice-President, Webster Engineering Co., Chicago

WEST, OSCAR J., Sales and Consulting Engineer, Chicago

Indiana

CROW, MARTIN E., with Crow-Elkhart Motor Co., Elkhart

HETZEL, FREDERIC V., Chief Engineer, Link Belt Co., Indianapolis

Louisiana

BARELLI, JOHN S., Manager New Orleans Office, Heine Safety Boiler Co., New Orleans

Massachusetts

ALFORD, FRANK R., Superintendent, Chelsea Clock Co., Chelsea

BROOKS, JOHN C., Assistant to Vice-President, Goodell-Pratt Co., Greenfield

GUNNING, WILLIAM A., Chief Draftsman, American Optical Co., Southbridge

HALE, RICHARD A., Principal Assistant Engineer, Essex Co., Lawrence

McKITTRICK, PERCY A., Office Manager, Saco-Lowell Shops, Lowell

MILLIKEN, JAMES L., Resident Representative, Everett Mills, Lawrence

SMITH, CLAYTON O., Sales Manager, Norton Grinding Co., Worcester

Michigan

HARTMAN, DONALD E., Instruction Department, Consumers Power Co., Jackson

HEAVENRICH, OSMOND D., Chief Engineer, Detroit Pressed Steel Co., Detroit

OLSON, CHARLES W., Chief Tool Designer, Continental Motors Corp., Detroit

PLANCHE, ETIENNE, Chief Engineer, Dort Motor Car Co., Flint

SCHECKENBACH, JOHN A. V., Improvement Engineer, American Car & Fdy. Co., Detroit

Minnesota

GERRISH, HARRY E., Pres., Morgan-Gerrish Co., Minneapolis

JOHNSTON, WAYBURN E., Valuation Inspector, Northern Pacific Rwy., St. Paul

KOBEL, WILSON C., Assistant Chief Engineer, Minnesota Steel Co., Power Sta., Duluth

MORGAN, GLENN C., Vice-President, Morgan-Gerrish Co., Minneapolis

New Jersey

BROHPO, BENJAMIN N., Mechanical Engineer, Roessler & Hasslacher Chemical Co., Perth Amboy

FREDERICK, KARL L., Vice-President, Passaic Metal Ware Co., Passaic

PAUL, J. S., Factory Manager, Metal Process Co., Trenton

New York

CAUTLEY, JOHN R., Engineer Expert Dept., P. A. Frasse & Co., Inc., New York

GREEN, WILLIAM A., Manufacturer and Representative, American Engineering Concerns in Europe, New York

HUNTER, CHARLES F., Superintendent Repair Shop and Chief Engr. Power Plants, Witherbee, Sherman Co., Inc., Mineville

LEONARD, ALBERT P., Assistant Chief Engineer, Honolulu Iron Works Co., New York

McALLISTER, JOHN E., Assistant to President, Liberty Fuse & Arms Corp., Long Island City

MacFARLAND, EDWARD H., Steam Turbine Inspector, General Electric Co., Schenectady

MAIS, ALBERT F., Chief Engineer, Fulton Motor Truck Co., Farmingdale, L. I.

MARTIN, JOHN F., Superintendent, Neptune Meter Co., Long Island City

MORROW, JAMES E., Secretary and Manager of Production, Morrow Mfg. Co., Elmira

DE NEMETH, ZOLTAN, Engineer Power Plant Designs, James Stewart & Co., New York

SHIRADY, CHARLES D., Engineer, Van Siclen & Co., New York

SHAW, HUBERT A., Metallurgist, American Can Co., Geneva

WAGNER, JAMES J., Engineer, New York Central R. R. Co., New York

Ohio

[illegible]ANSON, JAMES F., Assistant to J. D. Lyon, [illegible] Engr., Cincinnati

[illegible]ARSON, JAMES R., [illegible], [illegible] Mach. Tool Co., Cincinnati

[illegible]ELL, M[illegible], Mechanical Draftsman, The A[illegible] Machine Co., Alliance

STEVENS, WILLIAM N., Machine Tool Design, Cincinnati Milling Mch. Co., Cincinnati

WALMSLEY, HAROLD M., Resident Engineer, S[illegible] & [illegible]endy, Cincinnati

Pennsylvania

HENRY, [illegible], Construction Engineer, American Sheet & Tin Plate Co., Pittsburgh

LELAND, EDWARD D., Superintendent Compressing Stations, Philadelphia Co., Pittsburgh

LIVERSIDGE, HORACE P., Operating Engineer, The Philadelphia Electric Co., Philadelphia

SCHULTZ, WALTER F., Chief Engineer, Driggs Seabury Ordnance Co., Sharon

WEBSTER, HARRY D., Mechanical Engineer, Bessemer & Lake Erie R. R. Co., Greenville

WHITCRAFT, ARTHUR, Sales Engineer, American Manganese Steel Co., Pittsburgh

Tennessee

BADGER, HARRY S., Superintendent Power Sta. and Sub Sta., Nashville Rwy. & Light Co., Nashville

Texas

MOELLER, WILLIAM, Suprintendent, Texas Portland Cement Co., Houston

Vermont

FULLAM, EBEN J., Secretary, The Fellows Gear Shaper Co., Springfield

Virginia

LEE, CAZENOVE G., JR., with E. I. du Pont de Nemours & Co., City Point

Wisconsin

BROWN, ARTHUR J., Chief Draftsman Electrical Dept., Allis-Chalmers Mfg. Co., Milwaukee

Canada

CAMERON, N. C., Chief Engineer, Imperial Tobacco Co. of Canada, Ltd., Montreal

France

SCHUTZ, HARRY M., Engineer, Niles-Bement-Pond Co. of U. S. A., Paris

FOR CONSIDERATION AS ASSOCIATE-MEMBER OR JUNIOR

Delaware

BANKER, WALTER B., Resident Engineer, E. I. du Pont de Nemours & Co., Wilmington

Illinois

MARLOW, FRANK W., Chief Engineer, Armour & Co., Chicago

MILLER, JOSEPH S., Mechanical Engineer, Kewanee Boiler Co., Kewanee

Massachusetts

HAMILTON, DON A., Mechanical Engineer, John Bath & Co., Inc., Worcester

Michigan

GILLOOLY, JOHN H., Draftsman, Steere Engineering Co., Detroit

KAMMERER, NELSON C., Chief Draftsman, Metalwood Mfg. Co., Detroit

Nebraska

SLOMAN, HUBERT E., Assistant Superintendent of Buildings and Construction, J. L. Brandeis & Sons, Omaha

New York

CONLEY, MURRAY C., Mechanical Engineer, Henry L. Doherty & Co., New York

HUNICKE, CLARENCE C., Patent Attorney and Attorney at Law, New York

LOGAN, ORWELL, Chief Engineer, Jensen Creamery Machinery Co., Long Island City

McHOLLAN, JAMES A., Assistant Engineer, The R. P. Bolton Co., New York

MEAD, FRANK R., Assistant to Chief of Department of Gauges, L. R. Kenyon, Munitions of the British Government, New York

MORLEY, MARCUS D., Assistant to Engineer of Tests, Edison Electric Ill. Co., Brooklyn

SERRELL, JOHN J., Vice-President, Smith-Serrell Co., Inc., New York

SMITH, ALBERT T., Manager, The R. U. V. Co., New York

TERWILLIGER, DAVID M., Engineer of Tests, Operating Department, Edison Elec. Ill. Co., Brooklyn

WHEELER, WILLIAM H., Purchasing Engineer, Austin Baldwin & Co., New York

Pennsylvania

KIRK, DONALD, Draftsman, Carnegie Steel Co., Homestead Works, Munhall

WARD, ROY J., with Shephard Electric Crane & Hoist Co., Pittsburgh

Virginia

DUFFEY, PAUL R., 1st Assistant Master Mechanic, Mathieson Alkali Works, Saltville

Wisconsin

HENSZEY, ROY O., Engineer and Architect, Carnation Milk Products Co., Oconomowoc

MOYER, WILL D., Public Utility Inspector, Wisconsin R. R. Comm., Madison

FOR CONSIDERATION AS JUNIOR

Alabama

NECROLOGY

CHARLES ALEXANDER CANDA

Charles Alexander Canda was born in Summit, N. J., on June 18, 1869. He received his education in the public schools and Stevens Institute, graduating from the latter in 1893. He soon after became associated with the Brush Electric Light Co., New York, where he remained until 1899. During this time he designed a direct-current arc lamp whereby the top and bottom carbons were controlled in the head of the lamp.

In the latter part of 1899 he affiliated with the Canda Manufacturing Co., manufacturers of automobiles, serving in the capacity of assistant to the superintendent, acting superintendent from 1900 and superintendent in 1901. Early in 1902 he assumed the duties of secretary and became part owner of the Chrome Steel Works, Chrome, N. J., holding this office at the time of his death.

Mr. Canda was granted a number of patents, among them being a clamping device for tappets, wheels or shaft couplings, and an improvement on a machine for making tubes and tires.

Mr. Canda became a member of the Society in 1916. He died at his residence in Elizabeth, N. J., February 8, 1917.

FRANK EUGENE HOLT

Frank Eugene Holt was born at Holyoke, Mass., in 1856. He served his apprenticeship with Eddy and Stone, of Worcester, Mass., and between 1876 and 1893 was associated with The Washburn & Moen Manufacturing Co., during which time he was in charge of their Union Street shop, and did work in connection with the erection of rolling mills for that company. In 1893 he accepted the position of master mechanic with the Spaulding & Jennings Co., and when this plant was absorbed by the Crucible Steel Company of America, he went to the Singer Manufacturing Co. to design and erect a rolling mill to produce small steel shapes, and thereupon was put in charge of the power houses of the company, at the Elizabethport factory, and performed advisory duties in connection with the power operation of their plant at St. Johns, Canada.

At the time of his death, Mr. Holt was President of the Singer Club, and a member of the Singer Engineering Society. He joined the Society in 1900. He died on February 4, 1917.

CAPTAIN WILLIAM HENRY JAQUES

Capt. William Henry Jaques was born in Philadelphia, Pa., December 24, 1848. He received his early education in the schools of New Jersey and entered the United States Naval Academy as midshipman in 1863. He graduated from the Academy with honors in 1867 and was detailed for active service immediately. He became ensign in 1868, master in 1870, and lieutenant in 1871. At various times he performed duties as aide to the President, the Secretary of the Navy, and the Commandant of the New York Navy Yard.

Between 1870 and 1874 he was assistant in the United States Coast Survey; from 1874 to 1878 he assisted the New York Board of Education in technical education; in 1881-1882 was assistant inspector of ordnance; and from 1883 to 1885 member and secretary to the Senate Committee on Ordnance and Warships. During this time he succeeded in introducing the system of fluid compression and hydraulic forging of heavy masses of steel, and was the inventor of many improvements in the manufacture of heavy ordnance and armor and the leading exponent of employing nickel in steel.

Captain Jaques resigned his commission in the Navy in 1887 to accept a position with the Bethlehem Steel Co. as ordnance engineer. In 1894, having successfully carried out the various developments he had advised, he retired. Soon after he associated himself with Horace See, eminent engineer and architect, in general engineering and consultation in connection with the manufacture and treatment of guns, armor, and other war material. In 1895, at the request of the governor of New Jersey, he began the organization of a naval reserve for that state and was commissioned captain. He held this command until 1898, when loss of health compelled him to resign.

Although he had already done his full share in bringing the ordnance and armor of the United States to a high standard of excellence, he undertook in 1897 the development of submarine torpedo boats and accepted the presidency of the Holland Submarine Boat Co. In 1909 he became president of the Hampton Water Works Co., Little Boar's Head, N. H., and in 1913 president of the Progress Mfg. Co., Boston, Mass., which offices he held at the time of his death, October 23, 1916.

Captain Jaques was the author of numerous monographs and books on heavy ordnance, armor, torpedoes, solar radiation, etc., and was an authority on water engineering. He was one of the international jury on marine transportation and war material at the Columbian Exposition of 1893.

Besides being a Member of the Society (1893), he was also a life member of the Society of Naval Architects and Marine Engineers, and a member of the American Institute of Mining Engineers, the American Society of Civil Engineers, the Iron and Steel Institute, the Institute of Civil Engineers (Great Britain), the Institution of Mechanical Engineers (Great Britain), the Institution of Naval Architects (Great Britain), and other organizations.

PAUL H. KENDRICKEN

Paul H. Kendricken was born in Galway, Ireland, in 1834. He set sail for America as a lad of seven, and landed in Boston in 1842. In 1852 he went as an apprentice to Walworth and Nason, then considered pioneers in steam and hot water heating of houses, and then became associated with the Union Steam Gauge and Low Water Detector Co. In 1859 he was put in charge of the steam works of the Massachusetts Steam Heating Company, and was later promoted to acting superintendent.

Not long after, he entered the Naval Service as third assistant engineer, was promoted to second assistant engineer, and remained in active service until the end of the war. At its termination he became associated with Clagston and Company, for whom he acted as superintendent. After some changes, the firm became Ingalls & Kendricken, and under Mr. Kendricken's guidance developed into a successful business. The firm was incorporated in 1905, Mr. Kendricken remaining as president and treasurer until the time of his retirement, five years ago.

Mr. Kendricken held various public offices, including that of councilman, alderman, state senator, park commissioner for the City of Boston, etc. He was also a member of the Executive Committee of the National Association of Master Steam Fitters.

He became a member of the Society in 1910.

JOSEPH STEHLIN

Joseph Stehlin, who was born in New York City in 1875, received his early education in the public schools here, and later in the Stevens Preparatory School and the Stevens Institute of Technology, graduating from the latter in 1898 with the degree of M.E.

Directly upon leaving school, Mr. Stehlin entered the drawing-room of P. Pryibil and soon after that of C. W. Hunt & Co. His shop experience was obtained while with J. Rupert and as assistant engineer with the Nestle Food Co., 1899. In 1900 he became associated with the N. Y. C. & H. R. R. R. as assistant mechanical engineer, and in 1903 became mechanical engineer, superintending erection of power stations, cooling plants, water stations, lighting, and power and steam equipment of yards and buildings. He severed his connection with the N. Y. C. & H. R. R. R. in 1906 and founded the Stehlin-Miller Henes Co., steam and electric engineers and contractors. In 1908 he became also associated with the Farmers Feed Co., of which his father was president, and in 1909, upon the death of his father, he succeeded to the presidency of the company and continued so until the time of his death, January 22, 1917.

Mr. Stehlin was elected an Associate in the Society in 1905.

KENNETH TORRANCE

Kenneth Torrance was born in Brooklyn, New York, in 1863. He went to Stevens High School for one year and then to Stevens Institute, and graduated with the class of 1884. He remained an active alumnus throughout the rest of his life and founded an enthusiastic association of Stevens alumni in Schenectady.

After leaving college he went to the Worthington Pump Co. and was later with the Brooklyn Water Works as Superintendent of the Ridgewood and all the Long Island pumping stations, which position he filled until 1906. He then joined the General Electric Co. to take charge, at its Schenectady Works, of its power stations, pumping stations, water, steam and compressed air systems, heating, etc. He carried out the reconstruction of the entire heating system for this works and was responsible for the design of all heating for the many new buildings erected at this works during his connection with the company. He carried out extensive additions to the power plants which resulted in very successfully meeting most extraordinary requirements in connection with emergency power supply, steam for testing, etc. He was actively connected with the development of the steam flow meter.

Kenneth Torrance had a rare gift for handling men. In Brooklyn and later in Schenectady he held the loyalty and respect of those under him as few men do. He had a host of friends, and wherever he went he made more.

He was a member of the Society for many years and also of the American Waterworks Association, the Society of Engineers of Eastern New York, the Schenectady Stevens Club, the Delta Tau Delta fraternity, the Mohawk Club, and the Mohawk Golf Club.

He died on September 13, 1916, at Mount Kineo, Maine, where he had gone to convalesce after a severe illness.

AMONG THE SECTIONS

SINCE the last issue of The Journal went to press, the President made an extended trip, which took him as far west as the Minnesota Section whose headquarters is at Minneapolis–St. Paul. En route he visited the Sections at Buffalo, Chicago and Indianapolis. At each of these places he received a rousing welcome and his spirited address on Service to the Country in This Crisis brought forth enthusiastic responses.

Although he has as yet been in office less than four months, Dr. Hollis has already visited ten Sections and eight Student Branches, addressing several thousands of engineers. He has spent a total of thirty-four days in these activities, which are additional to the time consumed in the attendance at Council and various committee meetings and in carrying on a voluminous correspondence relative to the Society's business.

As the present issue of The Journal goes to press the Secretary is starting on a trip to visit Sections and Student Branches not covered by other officers during the current fiscal year. These will include the Sections at Cincinnati, Chicago, Milwaukee, and probably Kansas City, where the members are considering organizing a Section. Several Student Branches will also be covered.

These data will serve to emphasize the national importance of the Society, which now boasts of twenty Sections located in sixteen States of the Union. It is the ambition of the Secretary that each Section and Student Branch receive a visit at least once a year by one of the Executive Officers of the Society.

Recently a visit was made by Prof. L. P. Breckenridge to the Sections at Atlanta and New Orleans, and these places wholesomely entertained the representative of the New Haven Section, and received in return the benefit of many valuable suggestions as to the methods the New Haven Section pursues

in developing engineering coöperation in Southern New England.

In the March issue of The Journal on page 241 there appeared a report presented at the Conference of Section Delegates at the last Annual Meeting, entitled Suggestions Regarding Local Section Activities. Mr. D. Robert Yarnall was one of the Committee to prepare this report and his name should have been included with Messrs. H. R. Setz and W. G. Starkweather.

SECTION MEETINGS

ATLANTA

February 5—The members of the Atlanta Section devoted February 5 and 6 to the entertainment of Prof. L. P. Breckenridge, Mem.Am.Soc.M.E., who visited their city. At a luncheon tendered him, Professor Breckenridge spoke of the advantages of the different sections and told of the activities of the New Haven Section. It was felt that his talk was a great incentive to the members of our Section.

Earl F. Scott,
Section Chairman.

BALTIMORE

March 13—A meeting of the Baltimore Section was held in the Engineers' Club and was addressed by John T. Broderick. The following resolution was moved and seconded and adopted by the Section, subject to approval by the Council of the Society.

> "In view of the grave crisis which our country is facing, and in recognition of the stand recently taken by the President of the United States for the protection of American rights and American lives on the sea.
>
> "BE IT RESOLVED that we, the members of the Baltimore Section of the American Society of Mechanical Engineers, at a meeting held Tuesday, March 13, 1917, first do pledge ourselves to the support of the President and Congress in maintaining our rights; and, second, we pledge our services to our country in case it is forced into war as the only means of securing and maintaining these rights.
>
> "BE IT FURTHER RESOLVED that a copy of this resolution be sent to the President, at the White House, at Washington, and to Senators and Representatives."

Mr. Broderick, who holds the position of Supervisor of Special Bureaus on the Baltimore and Ohio Railroad, gave an address on Safety Work on this road, showing moving pictures that this company uses to impress the Safety First idea on the men. Mr. Broderick said in part: "In the 'Safety First' movement which swept the country during the fall of 1911, the Baltimore and Ohio was the first company in the East to organize a definite campaign against personal injury to employees, renewing its efforts to safeguard passengers and its property. In the words of President Daniel Willard, the principle took precedence 'over everything else,' and still does with unabated sincerity of purpose.

"'To perpetuate the propaganda of Safety First, the Railroad has resorted to every practical means of education—precept, instruction, example, proof and discipline. A General Committee was organized in Baltimore, serving on which were the officials best adapted to the preachment of safety. Upon the various divisions, Divisional Committees were formed consisting of the superintendents and staffs as permanent members and men from the ranks selected every three months. The General Committee held mass-meetings at principal terminal points along the system, attracting large crowds of railroad men, at which addresses were made by the Committeemen and stereopticon views shown, all portraying various phases of the subject—Safety—and its allied subject—'Health and Sanitation.' Such Division Committees meet once each month, and at these gatherings receive and record many of the suggestions made by the employees themselves. The men enter into the spirit of the campaign, and divisions vie with one another to head the list of decreases in accidents. Last year the men on these Committees made 17,000 suggestions for improving working conditions, 96 per cent of which were recorded and acted upon. . .

"Through the maintenance of the 'Safety First' Bureau, which has direct charge of this work, supervising the organization and work of the Divisional Committees, thoroughly organized and sustained efforts are being made to reduce accident on each division of the System to the minimum."

A. G. Christie,
Section Secretary.

BOSTON

March 8—A joint meeting was held by the Boston Section and the American Institute of Electrical Engineers. W. B. Potter, Mem.Am.Soc.M.E., spoke on Electric Transmission for Motor Cars.

Mr. Potter illustrated his lecture with many interesting lantern slides, dividing his subject into the application of this system of propulsion to railroad cars and to automobiles, and tracing the development of the system within the last two or three years to its present condition.

W. G. Starkweather,
Section Secretary.

BUFFALO

April 14.—The Engineering Society of Buffalo will hold a meeting at the Hotel Statler, at which time there will be a discussion of Educational Systems and Apprenticeship Systems.

February 15—A resolution was passed for a preparedness post-card canvass, asking each of the 600 members to state in what way he would be most proficient in time of war and if he would be willing to volunteer his services.

Charles F. Kettering, Mem.Am.Soc.M.E., Vice-President of the Dayton Engineering Laboratories, gave a most interesting lecture on the evening of February 28, taking as his topic Pure Science Applied to Engineering, mixing humor, wit, politics, story and reminiscence with technical considerations. He showed many articles of common commerce which science has made possible, finding a substitute for scarce genuine material. He discussed the fundamental side of research, and his reminiscence concerning many problems of the experimental research engineer was of an interesting nature.

March 7—An enthusiastic and very large audience listened to addresses on March 7 by Dr. Ira N. Hollis, Pres.Am.Soc.M.E., John Younger, Mem.Am.Soc.M.E., William Elmer, Mem.Am.Soc.M.E., Major Frank S. Sidway, A. Conger Goodyear, Evan Hollister, Charles M. Manly, Mem.Am.Soc.M.E., and Herbert A. Meldrum.

Dr. Hollis spoke on Services to Our Country in This Crisis, explaining the condition of this country and impressed upon his audience that the only way to overcome this inefficient state is by unity of purpose, coöperation with our fellow workers, loyalty to our country and preparation for war against war, and showed the part the engineer must take. Mr. Younger told of classes being formed for the instruction of men in field fortification, telephony and transportation so that if necessary this city will be able to send trained men into the field. Mr. Elmer followed with a description of the part the railroads will play in time of war. Major Sidway urged action on the training of youth. Mr. Meldrum said that the mobilization of the troops on the border had shown the great need for military training and that it was time for the country to act. Mr. Goodyear urged the furtherance of the officers' reserve corps and defined its duties. Mr. Hollister spoke on compulsory military training, followed by Mr. Manly, a pioneer of aviation in the United States, who advised people to show their sentiments on the topics of to-day by continually urging their congressmen to carry out their program.

Louis J. Foley,
Assistant to Secretary.

DETROIT

April 20—J. W. Lieb, Mem.Am.Soc.M.E., will be the speaker at the meeting of the Detroit Section, taking as his subject Leonardo da Vinci—Artist, Philosopher and Engineer.

INDIANAPOLIS

March 12—A meeting held by this Section with the Engineers' Club of this city was addressed by Ira N. Hollis, Pres.Am.Soc.M.E., the subject discussed was the Relation of the Engineer in Civil Life to the Present National Crisis. A committee was

... services of the Engineers' Club with which ... affiliated to the government and also to the state and ... for such service as the emergency might indicate ... suitable for them to render.

W. H. INSLEY,
Section Chairman.

MERIDEN

March 9—At the regular monthly meeting of the Meriden members of the A.S.M.E. on March 9, Frank L. Rowntree, Mem. Am.Soc.M.E., spoke of the growth of the Society in Meriden; Charles N. Flagg, Jr., Mem.Am.Soc.M.E., read a paper on the Isolated Power Plant, after which the meeting was opened for general discussion, remarks being made by J. A. Hutchinson, Mem.Am.Soc.M.E., D. P. Griswold, Herman Minkwitz and C. K. Dechard, Mem.Am.Soc.M.E., and others. The next meeting will be held on April 5.

NEW ORLEANS

April 2—The New Orleans Section will hold a meeting, at which the subject for discussion will be Preparedness. The principal paper will be given by A. M. Lockett, Mem.Am.Soc.M.E. and member of the Naval Consulting Board which made the recent industrial census for the army and navy.

NEW YORK

March 13—Mobile Armaments formed the subject of a paper by Andrew M. Coyle, Mem.Am.Soc.M.E., before the New York Section at this meeting. The timeliness of the subject was responsible for an unusually large attendance.

Mr. Coyle, who is with the Board of Coast Defense Engineers, U.S.A., outlined the necessity for an adequate system of mobile guns of both large and small calibre, mounted on railway cars, that could be quickly moved from place to place to protect the numerous stretches of coast line between the fortifications which now guard the approaches to our important harbors. He showed a number of pictures of armored cars now in use along the European battlefronts, and told in a general way what is being done in this country. The speaker showed the various means that have been developed to take up the recoil and briefly mentioned a new device now being worked out by the army engineers in which this problem has been greatly simplified. In the discussion that followed, L. W. Luellen described and illustrated the Luellen-Dawson system of mounting mobile guns—a system that requires permanent concrete bases over which the car is run and the gun is mounted.

A. D. BLAKE,
Section Secretary.

PHILADELPHIA

April 24.—There will be an entertainment for Dr. Ira N. Hollis, Pres. Am.Soc.M.E., by the Philadelphia Section at the Engineers' Club.

March 15—A joint meeting with The Franklin Institute was addressed by Jerome C. Hunsaker, assistant naval constructor, Navy Department, Washington, on Design, Construction and Equipment of a Modern Military Aeroplane.

Mr. Hunsaker spoke of the importance attached to the mastery of the air by those engaged in the present conflict in Europe and the efforts made to gain and maintain this prestige, emphasizing the extreme rapidity with which different types were evolved, due to the keen competition for supremacy. The speaker illustrated his remarks with lantern slides, and moving pictures were also shown of the first air flights in this country by the Wright brothers and of various air crafts in Europe, among the latter of which was the destruction of a German aeroplane by French machines, and 5000 ft. drop in a parachute from a kite balloon.

W. R. JONES,
Section Secretary.

PROVIDENCE

April 23—The Providence Engineering Society will hold a meeting which has been arranged by the Efficiency and Scientific Management Department. The subject will be Routing-Principles, Machine Symbols, etc.

ST. LOUIS

April 18—At this meeting one of the leading refrigeration engineers of St. Louis will give a talk on Refrigeration Problems of a Modern Hotel.

STUDENT BRANCHES

THAT the spirit of coöperation existing in the engineering profession is extending to our coming engineers, is reflected in the plans for joint meetings of Student Branches on the Pacific and Atlantic Coasts and in the Middle West.

On March 24 a joint meeting of the Branches at Leland Stanford University and the University of California was held at the latter university. As this is taking place as The Journal goes to press a detailed account of it must be deferred until the May issue.

Meanwhile, in the East, a committee of Student Members is at work perfecting plans for a joint meeting of the Branches at Brooklyn Polytechnic Institute, Columbia University, Lehigh University, New York University, Rensselaer Polytechnic Institute and Stevens Institute of Technology. Representatives of Cornell University and Ohio State University will also probably be present. In all, more than three hundred students are expected to attend, making this the largest meeting of students ever held under the auspices of the Society.

The meeting will be held at the Engineering Societies Building in New York on Friday, April 13. A professional session will begin at 5 p. m., which will be addressed by Prof. Arthur M. Greene, Jr., Member of Council Am.Soc.M.E., and Prof. Lionel S. Marks, Mem.Am.Soc.M.E., and probably also by Prof. Robert H. Fernald, Manager Am.Soc.M.E., Prof. Charles E. Lucke, Mem.Am.Soc.M.E., and General Leonard Wood.

A buffet supper will then be served, followed by a smoker. During the evening, entertainment will be furnished by college glee clubs, mandolin and banjo club, professional entertainers, etc., and light refreshments will be served.

At the Spring Meeting in Cincinnati (May 21-24) a third joint meeting of Student Branches will be held. This will take place at the University of Cincinnati, and it is expected that all of the Student Branches in that Section of the country will participate, including those at the University of Cincinnati, Purdue University, Ohio State University, Case School of Applied Science, Carnegie Institute of Technology, University of Pittsburgh and State University of Kentucky. This is the first time such a gathering has been held in connection with a general meeting of the Society, and it is hoped all branches who can do so will make every effort to participate.

During the past month the list of Student Branches was brought to a total of forty-five by the addition of the University of Oklahoma, at Norman, Okla. Prof. J. H. Felgar, Mem.Am.Soc.M.E., Dean of the College of Engineering and Director of the School of Mechanical Engineering, has been appointed Honorary Chairman of the Branch.

ARMOUR INSTITUTE OF TECHNOLOGY

January 31—The meeting of the Student Branch of the Armour Institute of Technology was devoted to discussions by students on subjects of mechanical interest. N. Steindler explained in detail the Construction of a Water Softener. B. Robecheck followed with a paper on Heat and Emulsion Test of Oils. Mr. Kerr's subject was The Compression of Air and Mr. Bretting told of the By-Products of the Forests.

On Wednesday evening, February 14, Prof. George F. Gebhardt, Mem.Am.Soc.M.E., spoke on Advice to the Engineer, which was received with much appreciation by the members.

Mr. Sweniford and H. S. White were the speakers on February 28. Mr. Sweniford gave an illustrated talk on Safety Engineering, explaining the different ways in which accidents occur and may be lessened. His illustrations showed many ways of protecting machines in machine and wood-working shops. Mr. White followed with a very clear description of the Wood Dual Electric.

A smoker was held on March 7, to which both freshmen and sophomores were invited. This was a form of get-together movement in which each member of the branch endeavored to make the lower-classmen feel that they would be cordially welcomed at all meetings and aided in taking up the work when their turn came.

E. W. Harris,
Branch Secretary.

BUCKNELL UNIVERSITY

March 5—The Student Branch of Bucknell University held its last regular monthly meeting, F. E. Benedict and C. J. Hay giving the addresses.

Mr. Benedict gave a very comprehensive talk on Railroad Machine Shop Practice. He was followed by C. J. Hays, who spoke on The Modern Gas Producer Practice, giving a detailed description of a modern plant and also some data showing the rapid development of the industry in the last decade.

C. M. Kriner,
Branch Secretary.

UNIVERSITY OF CALIFORNIA

February 14—On this date Mr. Chilcot '15 related his experiences as a scientific manager, taking the members theoretically through both the Chalmer and Ford Automobile Works and comparing the efficiency of the plants in the East with those of the West.

At a meeting on February 28, Professor Tour of the Mechanics Department of the University, read a paper on Entropy and its relation to Temperature. The pressure-volume analogy to entropy and temperature aided materially in making clear to the members just what entropy is.

A joint banquet is being planned with the Leland Stanford Jr. University Student Branch for the evening of March 24.

John H. Fenton,
Branch Secretary.

CARNEGIE INSTITUTE OF TECHNOLOGY

February 14—The regular monthly meeting of the Student Branch of the Carnegie Institute of Technology was held, when Prof. G. H. Follows, head of the Department of Machine Design, addressed the students on The Bull's Eye: Hitting It, Chasing It, Missing It, Often. He opened his talk with a description and brief history of the science of archery and likened the aims, successes and failures of the engineer to meet his goal to the archer's attempt to strike the bull's eye of the target. He pointed out that while all engineers strive to make a bull's eye, there are very few who can predict before a machine is built just what it will do when put into operation. Professor Follows concluded by recounting many interesting and some rather amusing experiences he has had during his career as a mechanical engineer.

J. H. Davis,
Branch Secretary.

CASE SCHOOL OF APPLIED SCIENCE

February 7—A regular meeting of the Student Branch of the Case School of Applied Science was held at the Case Club. John E. Washburn, Mem.Am.Soc.M.E., of the National Carbon Co., of Cleveland, O., gave a practical and interesting talk on the Heat Treatment of Iron and Steel. Mr. Washburn has had much opportunity to observe the peculiar characteristics of our industrial metals and was therefore in position to cite many interesting examples of the behavior of steel under heat treatment. To illustrate extreme properties obtainable by heat treatment, he displayed two rods made from the same piece of stock but differently treated. One of the rods possessed such strength that when secured in a vise, it could not be bent by one man's pulling at a distance of several feet from the jaws; on the other hand, the other was so weak that it could be broken by the fingers. The latter sample, he explained, if properly reheated and treated could be made as strong as the first.

March 14—Frederic A. Parkhurst, Mem.Am.Soc.M.E., was a guest of the Student Branch of Case School of Applied Science at their dinner and meeting.

Scientific Management was the topic of Mr. Parkhurst's talk. He traced the origin and development of the Taylor principles and described the elements requisite for the successful operation of that system. Mr. Parkhurst, who is organizing engineer of the Aluminum Castings Co., is to deliver a series of lectures on the same subject to the senior mechanical engineers, this being the initial talk.

A. Treuhaft,
Branch Secretary.

UNIVERSITY OF CINCINNATI

February 16—At the regular monthly meeting of the Student Branch of the University of Cincinnati, H. S. Ernst and A. W. Schneider, both seniors, gave the addresses. Mr. Schneider spoke on Mining Methods in Anthracite Coal Fields of the Lehigh Coal & Navigation Company in Pennsylvania. He pointed out the various duties and responsibilities of mechanical engineers in keeping all equipment in good repair and operation with shut downs. Mr. Ernst followed with Modern Automobile Production at the Willys Overland Company of Cleveland, Ohio. Starting with the parts of the car from raw stock, he added each part in its turn of assembly, until the car was completed. Designs, methods of machinery and intricate parts of the construction were fully explained by Mr. Ernst.

Henry A. Wolsdorf,
Branch Secretary.

COLORADO STATE AGRICULTURAL COLLEGE

February 19—The Student Branch of the Colorado State Agricultural College held a meeting, at which time the speakers were E. C. Johnson, M. L. Gorton and Prof. L. D. Crain, Mem.Am.Soc.M.E.

Mr. E. C. Johnson gave a paper regarding the methods and systems used in the Denver Rock Drill Machinery & Manufacturing Co. Mr. Gorton gave a talk in the form of advice regarding the value of summer work and the advantages gained which the college course cannot give. Professor Crain told of the methods used at other institutions which he visited recently, giving advantages and points of comparison, thus bringing those present into closer touch with other institutions doing a similar work.

E. C. Johnson,
Branch Secretary.

COLUMBIA UNIVERSITY

King of the Rails was the subject of the highly interesting and instructive moving picture shown before the United Engineering Society of Columbia University. Prof. W. I. Slichter, Mem.Am.Soc.M.E., and Professor of Electrical Engineering at the University, accompanied the picture with explanatory notes. It included a historical review of the transportation field, leading up to the development of the electric operation of the Chicago, Milwaukee and St. Paul R.R. over the Continental Divide. Professor Slichter gave some very interesting data concerning this development and went thoroughly into the scheme of power distribution.

John L. Kretzmer,
Branch Chairman.

UNIVERSITY OF ILLINOIS

February 22—The Development of the Locomotive in the United States since 1829, was the subject of a paper, with slide illustrations, by J. H. Westbay, '17. Announcement that four prizes for the best papers delivered before the Branch and sent to the judges in manuscript form, would be given by the Pi Tau Sigma, the honorary mechanical engineering fraternity at the University, was made at this meeting.

[illegible] G. I. [illegible] President of the [illegible] Machine Co., were the speakers. Mr. [illegible] explained the special types of [illegible] design and told of the manner in which the [illegible] machines are [illegible]. The talk was [illegible] pictures showing several of these [illegible] in making a block [illegible].

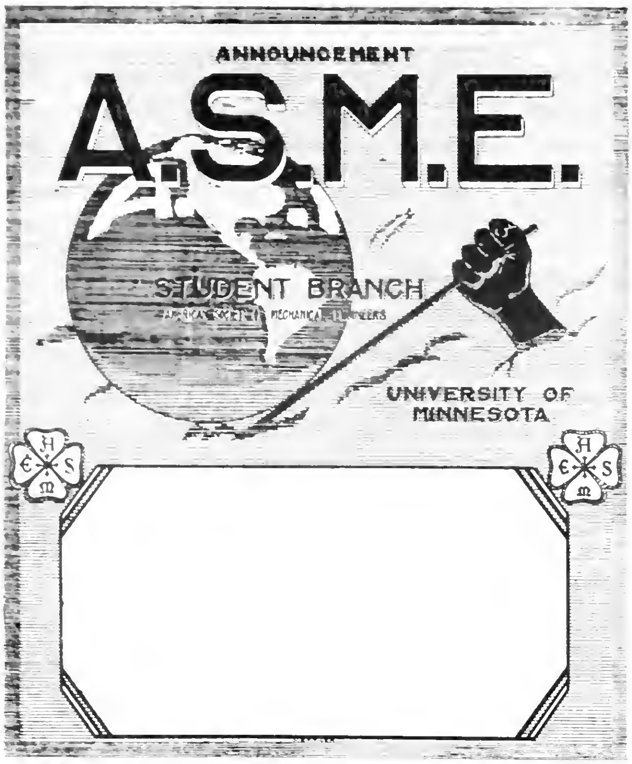
H. C. Dieserud,
Branch Secretary.

JOHNS HOPKINS UNIVERSITY

[illegible] 12—The Engineering Society of Johns Hopkins University [illegible] meeting of the year, with the Student Branch of the Am.Soc.M.E. in charge. Thomas W. Hind, of the Crown Cork and Seal Co., gave an instructive talk on the Harris-[illegible] Two-Cycle Diesel Engine, which he assisted in perfecting. With the aid of lantern slides he clearly showed its adaption to pleasure craft and boats of larger size, and gave among its many lucrative features the low fuel consumption, small upkeep and the simplicity of regulation.

[illegible] S. J. K. Shanahan, Secretary to the President of the Sparrows Point Branch of the Bethlehem Steel Co., gave a lecture [illegible] Ore to the Finished Product. Mr. Shanahan illustrated his talk by the use of moving pictures, thus showing in detail steps in the manufacture of steel from the mining of the ore in Cuba to the finished product ready for market. Both the talk and pictures aided greatly in giving the members clear and practical ideas on the methods used in the steel industry.

B. A. Sullivan,
Branch Secretary.



Minnesota Branch Announcement Blank

LEHIGH UNIVERSITY

[illegible] 25—D. MacIsaacs '17 and W. A. Haupt of the Bethlehem Steel Co. were the speakers at the meeting of the Student Branch of Lehigh University.

Mr. MacIsaacs spoke on Subway Underpinning, describing in detail the different methods and the reasons for underpinning. Mr. Haupt's subject was The Bonus System of the Bethlehem Steel Co. He stated that the cost of work depends upon having proper equipment, systematizing and planning the work and also upon obtaining the coöperation of the men. The last was secured through the bonus system. He explained the different methods of the system and showed how each was beneficial to both men and company.

F. M. Porter,
Branch Secretary.

LELAND STANFORD Jr. UNIVERSITY

February 7—H. P. Miller, Jr., '17 discussed the Lining of Tunnels with Reinforced Concrete at the meeting of the Stanford University Student Branch. He explained the various types of tunnels required on a hydro-electric development and described in detail the methods employed in lining those of the high-pressure type. The collapsible forms used and the manner in which they are set up in the tunnels was illustrated by means of sketches. He next explained the apparatus used for forcing the concrete into the tunnel through steel pipes under pressure and the procedure in placing and pouring the molds so that the work can proceed without interruptions.

A. L. Morgan,
Branch Secretary.

MASSACHUSETTS INSTITUTE OF TECHNOLOGY

February 27—F. L. Fairbanks, Mem.Am.Soc.M.E., described briefly the general layout and features of the apparatus at the Quincy Market Cold Storage and Warehouse Co. The meeting was followed a few days later by a trip through the plant by about fifty men who were conducted by Mr. Fairbanks and other engineers. The visitors were much interested in a 1000-ton vertical ammonia machine designed by Mr. Fairbanks, his description of the troubles he encountered and the resulting new features embraced in the construction proving most interesting and instructive.

Edward W. Rounds,
Branch Secretary.

UNIVERSITY OF MICHIGAN

March 1—The Branch held a regular monthly meeting, with T. Tobey, Fred Sawin and A. E. Hecker as the speakers. Mr. Tobey's subject was Fuel Oil Testing and he discussed the production of fuel oils from the raw material, the government specifications for purchasing of oil and the advantages of oil over coal as a fuel. In his paper on Alcohol as a Fuel, Mr. Sawin brought out the fact that the raw material was unlimited in supply and spoke of the special design of engines burning alcohol. Mr. Hecker showed the distribution of concrete from the mixer to the forms by the most modern methods in his lecture on The Mechanical Handling of Concrete, which was accompanied by lantern slides.

Karl Bintz,
Branch Secretary.

UNIVERSITY OF MINNESOTA

The accompanying novel and attractive poster has been designed by one of the members of the Student Branch of the University of Minnesota. The original, which measures 11 in. by 13 in., is to be used by the branch to announce its meetings; notice of these will be inserted in the blank space provided for that purpose.

February 12—An illustrated lecture was given by Mr. Goetzenberger, '14, on Power Driven Machinery. E. F. Jones and A. E. Rosenbloom discussed seminar subjects.

March 11-12—The branch held their annual meeting and were most fortunate in having Dr. Ira N. Hollis, President Am.Soc.M.E., address them. Dr. Hollis gave an extremely interesting talk which defended the profession against the assertion that machines have no emotional appeal, pointing out clearly that one who does not feel such an appeal has not the nature to be inspired by it.

Harry G. Fortune,
Corresponding Secretary.

UNIVERSITY OF NEBRASKA

March 6—J. S. Kelley, a member, gave an interesting lecture on the Manufacture and Use of S. K. & F. Ball Bearings. Mr. Kelley illustrated his talk with slides secured through the Society by courtesy of the company.

Orlo A. Powell,
Branch Secretary.

NEW YORK UNIVERSITY

Instead of the regular meetings in March two inspection trips were made by the Student Branch of New York University. The first to the Singer Sewing Machine Company's plant at Elizabethport, N. J., where the conveyor or continuous system of casting sewing machine frames was of especial interest; the other to the De La Vergne Machine Company's plant in New York where the blast furnaces, drop forging department, automatic cam cutting machines and the rolling mill and work on the testing floor proved both interesting and instructive.

Joseph Gilman,
Branch Secretary.

OHIO STATE UNIVERSITY

February 15—The Student Branch of the Ohio State University held the first meeting for the second semester, when the following officers were elected: chairman, R. H. Wasson; vice-chairman, S. W. Bowser; secretary, F. E. Smyser; treasurer, R. R. Brown, and sergeant-at-arms, W. G. Owens.

March 7—H. W. Mowery, Mem.Am.Soc.M.E., and Mr. Morgan, Safety Expert of the Norton Mfg. Co., were the speakers at this meeting.

Mr. Mowery, who is connected with the American Abrasive Metals Co., spoke on Slipping Hazards, illustrating various slipping surfaces such as poorly constructed steps and other conditions in industrial life which are the cause of many accidents. The speaker stated that the companies taking precautionary measures to prevent such accidents were not only preventing them but were saving money in so doing; the application of the product which his company manufactures was also shown. Mr. Morgan followed with some general ideas on safety work describing how his company has saved money by the prevention of accidents.

March 8—An interesting paper on The Werkspoor Diesel Oil Engines was read by Mr. Rehn, a member of the senior class.

March 13—A large meeting was addressed by Ira N. Hollis, President Am.Soc.M.E., on Armed Neutrality of the United States and Will It Lead to War. Dr. Hollis explained the position of the engineer, who is the fundamental cause of all history and the basis of all civilization; he said that the real issue of this war is citizenship and the result shall be the life and triumph of democracy.

F. E. Smyser,
Branch Secretary.

OREGON STATE AGRICULTURAL COLLEGE

March 11—The Use of Powdered Coal as a Fuel was the subject of a paper by Mr. Thorne. Plans for future meetings were discussed and the committee reported on the new constitution.

Archer O. Leach,
Branch Secretary.

PENNSYLVANIA STATE COLLEGE

February 8—The Pennsylvania State College Student Branch held a regular meeting, when C. W. Holmberg '17 discussed Surface Resistence of Materials. This was followed by a description of the boiler test recently made by the senior mechanical students at Harrisburg.

At a meeting of the student branches of the various engineering societies, R. L. Sackett, Dean of the School of Engineering, and Arthur Holmes, Dean of the General Faculty, told of the proposed plan to publish an engineering paper in which each department of the School of Engineering will coöperate.

James A. Mease, Mem.Am.Soc.M.E., has resigned as Associate Professor of Machine Design at the College to take up other work. Practically every member of the Student Branch attended the farewell dinner tendered Professor Mease to express their sincere regrets at the loss of his active interest in the Student Branch, and to wish him every success in his new work.

Robert R. Rinkenbach,
Branch Secretary.

UNIVERSITY OF PITTSBURGH

March 8—The first meeting of the Branch was held on Thursday, March 8. Thomas Preston read a paper on Protective Coatings for Steel to Prevent Corrosion. [illegible] pared discussions by W. Thomas and [illegible]

[illegible]
Corresponding Secretary.

POLYTECHNIC INSTITUTE OF BROOKLYN

March 3—The Student Branch of the Polytechnic Institute of Brooklyn held a meeting, with B. Postman '17 as the speaker.

Mr. Postman illustrated his talk on Coal Gas Manufacture and Purification with cuts and diagrams. He gave a brief history of the first application of coal gas to useful purposes, going through all stages of the manufacture and purifying of the gas, clearly describing the apparatus used in each step.

George Chuer,
Branch Secretary.

PURDUE UNIVERSITY

February 20—W. T. Miller, Purdue '16, efficiency engineer with the Lafayette Boxboard Plant, spoke on the process of boxboard manufacture, at the meeting of the Student Branch of Purdue University. Mr. Miller spoke also of the efficiency work which has been carried out by this company which proved of much interest as this plant has been tested many times in the past by members of the faculty and of the student body and as a result has been equipped with all sorts of testing apparatus. Another result has been the increased efficiency of the power plant, which was originally designed for a 40 ton plant, to such a point that the present output is 102 tons per day. This was accomplished without any increase in the power equipment other than the addition of an economizer. Further tests on this plant will be made by the senior mechanical engineers under the direction of three of their body who will base their thesis upon it.

February 27—E. F. Hamilton, Purdue '14, with The Development of Radio Telegraphic Communication as his subject first gave a résumé of the history of the development of radio telegraphy, and then by means of formulae and diagrams brought out some of the more simple of its principles. His explanations were made more understandable by reference to actual pieces of apparatus which had been set up and connected to the University aerial. At the end of the meeting messages were intercepted from several stations, the sounds being heard by the audience through a megaphone to which a loud speaking telephone receiver was attached.

W. G. Schutt,
Branch Secretary.

RENSSELAER POLYTECHNIC ISTITUTE

March 5—Dr. Ira N. Hollis, Pres., Am.Soc.M.E., addressed the Student Branch and students of Rensselaer Polytechnic Institute. The Engineer and the National Crisis was the subject of his talk, which was both interesting and instructive, as it brought before the audience the important role the engineer may play in serving his country.

Eugene E. Harris,
Branch President.

VIRGINIA POLYTECHNIC INSTITUTE

March 10—A. H. Cox spoke on The Steam Turbine vs. the Steam Engine. He described the development of the engine and turbine, the natural applications and efficiency of each and the various types of turbines.

G. F. Minor,
Branch Secretary.

WASHINGTON UNIVERSITY

March 13—Training Workmen was the subject of a talk by Prof. Franz A. Berger, Mem.Am.Soc.M.E., at the meeting of the Student Branch of Washington University.

Professor Berger spoke in particular of vocational training and its development in foreign countries, illustrating his remarks with photographic views of the different shops and plants in general. He described one plant employing a very large force and building a

. . . of variety of machines, explaining in detail their system of apprenticeship and training.

Walter H. Kelz,
Branch Secretary.

UNIVERSITY OF WISCONSIN

January 11—Prof. G. L. Larson, Mem.Am.Soc.M.E., addressed the Branch on the benefits which could be gained from the organization. He also pointed out the advantages accruing from membership in the national society, to which the Student Branch is a stepping stone.

February 15—The election of officers for the following semester was the purpose of the meeting. The new officers are: President, Asher E. Kelty; vice-president, J. Frank Roberts; secretary, John M. Wood and treasurer, Arthur O. Bushholtz. On March 1 the members participated in a theatre trip.

March 11—Before a large audience, the past work of the Branch was reviewed by the president and new plans outlined; following this Prof. C. I. Corp, Mem.Am.Soc.M.E., and Prof. G. L. Larson, Mem.Am.Soc.M.E., incoming and outgoing Honorary Chairmen respectively, addressed the members.

Professor Corp pointed out the benefits to be gained by membership in the Branch, gave suggestions for coming meetings, emphasized the need for training in public speaking, and advocated Junior membership in the Society at the earliest date possible. It was also announced that Calvin W. Rice, Sec. Am.Soc.M.E., would shortly visit the Branch.

John M. Wood,
Branch Secretary.

WORCESTER POLYTECHNIC INSTITUTE

March 2—Victor W. Kliesrath, Mem.Am.Soc.M.E., gave an address on Modern Ignition Systems. Mr. Kleisrath divided his talk into two parts: in the first he gave a résumé of the progress of engineers along the subject of ignition systems, and in the second he brought home his points very effectively by means of lantern slides.

He described the spring type of magneto which the company first manufactured, taking his listeners step by step to the high-tension rotary magneto, then describing the new field opened up by the advent of the Dual and Duplex systems of ignition. Aided by the valuable apparatus which he had with him the speaker was able to demonstrate each type of which he spoke. At the close, Mr. Kliesrath exhibited a newly designed and built magneto for use on 12-cylinder engines, which will not appear upon the public market for several months.

H. P. Fairfield,
Branch Secretary.

EMPLOYMENT BULLETIN

THE SECRETARY considers it a special obligation and pleasant duty to make the office of the Society the medium for assisting members to secure positions, by putting them in touch with special opportunities for which their training and experience qualify them, and for helping anyone desiring engineering services. The Society acts only as a clearing house in these matters.

POSITIONS AVAILABLE

In forwarding applications, stamps should be enclosed for transmittal to advertisers; applications from non-members should be accompanied by a letter of reference or introduction from a member, such reference letter to be filed with the Society. Copy for notices must be in hand by the 15th of the month.

MECHANICAL ENGINEER, single, with experience in petroleom refining and training in Europe, for work in Mexico. State experience and education. 543.

ENGINEERS to train and develop in fundamentals of firm primarily engaged in distillation of coal tar, with resultant principal production of bituminous road and roofing materials. Ultimate object, filling operating positions in various plants as foremen, head chemist, assistant superintendents, or superintendents. Preferably men with chemical-engineering training. As contemplated work will eventually be executive, ability to handle men is desirable asset. 796.

DESIGNERS and SPECIAL ENGINEERS. High-grade technical engineers for heavy machine-tool and press designing; high-grade engineers capable of working out problems and designing conveying machinery for handling heavy material between machines; engineers to work out automatic press feeds, and layout draftsmen as assistants to head designers. Location Wisconsin. 871.

SALES ENGINEER, man 25 to 28, couple of years out of college. 879.

DRAFTSMAN who would invest some money in a prosperous shop and is familiar with horizontal return-tubular boilers and boiler-shop work in general. State age, experience and salary desired. Location New Jersey. 881.

DRAFTSMAN, first class, experienced in Corliss engines and heavy machinery for shop in Southern Ohio. Give all particulars in first letter. 888.

STRUCTURAL STEEL DRAFTSMAN. Salary depends on man. 889.

MACHINERY DESIGNER in steam-turbine department. Location Massachusetts. 894.

MECHANICAL or ELECTRICAL ENGINEERS, at least three years' training in technical school of standing, and one year's experience in some branch of electrical industry. Salary $90 per month. Location New York. 895.

OFFICE and FACTORY MAN with general experience. Must be qualified to investigate conditions of any department, report to office manager, and make suggestions of value. Salary to start, $20 to $25 per week. Location Connecticut. 896.

YOUNG ENGINEER on special-plant operation and investigation work in development of oil burners. Location Minnesota. 899.

MECHANICAL ENGINEER, 25 to 30, experienced in power pumps, power working heads as used in agricultural districts and pneumatic water-supply systems of various kinds installed to supply water for domestic use where waterworks are not otherwise available. Experience in design and construction desirable. Location Iowa. 900.

SALES ENGINEER. Technical knowledge of steam turbines, centrifugal pumps, fans and blowers essential. Selling experience desirable. Prefer college man under 30, with several years' practical operating experience and some sales work. First letter must contain complete record together with minimum salary. Location Pittsburgh. 903.

TRACER for drawings and blueprints and detail work in connection with engineering office. Location Pennsylvania. 905.

MASTER MECHANIC for lead-smelting plant, operating blast furnaces and concentrating mills; must be man of strong personality, capable of handling varied classes of mechanics. Give full details of education and experience. Location Utah. 906.

COMBUSTION ENGINEER, experienced in power-plant and stoker operation. Familiar with modern instruments. Location Philadelphia. 907.

ASSISTANT in setting premium wage rates in Ohio plant, manufacturing gas tractors. Young man who has had machine-shop experience. Excellent opportunity in line of work which is not crowded. College man preferred. 908.

SUPERINTENDENT of steel foundry. Strictly confidential. Eastern location. 909.

ASSISTANT to head of experimental department. Location New England. 911.

MECHANIC, high-grade, experienced in erecting machinery. Location Philadelphia. 913.

YOUNG ENGINEER to train in sales work in territory around New York and New England. Good personality and some commercial training. Salary $75 to $120 a month. 914.

DRAFTSMAN for same company as 901, accustomed to machine design, ventilating and heating work, to train in. Salary $18 a week to start. Location New York. 915.

SALES ENGINEERS to take charge of territory in Cincinnati, Indianapolis, Chicago, Detroit districts, or work can be handled by men working some other line. 916.

DRAFTSMAN for engineering department of New Jersey plant, with engineering education and experience; laying out and installation of new machinery in various departments of plant, providing for drives, foundations, etc., making drawings and plans for changes and improvements in equipment, and location, which include roofing, machinery, fire and steam stills for manufacture of asphalt, power equipment, crushing and conveying machinery. Salary $175 per month. 918.

STEAM EFFICIENCY ENGINEER for New York concern. Man thoroughly qualified, with operating experience and theoretical training. Duties involve traveling, principally examination of large steam-turbine plants, analysis of operation and introduction of improvements and economies. Position responsible and important. Salary adequate. Tact a requisite. Replies should give full record of qualifications and experience and should state salary. 921.

ASSISTANT CIVIL ENGINEER, CORPS OF CIVIL ENGINEERS U. S. NAVY. Examination will be held at the Navy Department, Washington, D. C. Address the Chief of Bureau of Yards and Docks, Navy Department, Washington, D. C. 924.

THREE DRAFTSMEN, pipe work, covering steam, hydraulic water, and air piping. Also machine designers and plant-layout men. Also first-class structural-steel and power-plant man. Location Ohio. 927.

DRAFTSMAN familiar with valve detail and design and with experience on estimating and layout work. Excellent opportunity for competent man. State age, experience in detail, references and salary expected. Apply by letter. Location New York State. 928.

HIGH-GRADE DESIGNER on hydraulic machinery. Permanent position. Must be reliable and have capacity for work. State age, nationality, experience, and salary expected. Location Michigan. 929.

ASSISTANT ENGINEERS, one to be responsible for the layout and installation of mechanical equipment in connection with power plants and industrial-building design; the other, a man who can take the responsibility of complete design on industrial buildings and write specifications. Positions pay $2,000 a year. Location Connecticut. 930.

ASSISTANT TO PURCHASING AGENT, to take care of engineering specifications and contracts and act as consulting engineer; position calls for general experience in mechanical engineering and in all matters relating to construction. Location New York State. 932.

MEN AVAILABLE

Only members of the Society are listed in the published notices in this section. Copy for notices should be in hand by the 15th of the month, and the form of the notice should be such that the initial words indicate the classification. Notices are not repeated in consecutive issues.

RAILWAY MECHANICAL ENGINEER, at present employed, age 37, technical education. Seventeen years' experience as railway machinist, draftsman, chief draftsman and mechanical engineer. Desires position with railway company, railway supply house or industrial plant, with greater responsibility and opportunity. Location immaterial. Salary $2400. D-118.

FUEL TESTING ENGINEER. Graduate, age 34. Seven and half years' experience in scientific testing of coal in industrial plants, for large coal company in Middle West. Desires position as combustion engineer for large user of coal. At present employed. D-119.

SALES ENGINEER. Graduate, [illegible] and selling of coal. Desires position [illegible] operating company. At present employed. D-120.

SUPERINTENDENT OF MACHINE SHOP or MASTER MECHANIC. Graduate M. E. High-grade tool designer and expert in standardization of product. Good organizer and executive with [illegible] years' practical experience in manufacture of high-grade machinery and precision tools. Salary $3600. D-121.

RESPONSIBLE POSITION with manufacturing or consulting engineering firm or with a high-grade school of technology desired by mechanical engineer with ten years' experience in machine shops and engine works. Fifteen years as head of a well-known engineering school. East preferred. D-122.

MECHANICAL AND DIESEL-ENGINE ENGINEER, with practical and theoretical experiences, who held successfully executive positions in design and manufacture of, and experimenting on marine and stationary Diesels in Europe and in America, desires to associate with engineering concern contemplating building Diesels, or already producing oil engines. Best references of ability, business knowledge, etc. D-123.

INDUSTRIAL ENGINEER. Technical graduate, age 29. Three years' experience as designing draftsman of industrial plants, transmission machinery and labor-saving devices. Past two years on industrial-engineering staff; experienced in time study, scheduling, planning, modern cost system, etc. Ability to increase production and decrease costs, standardize equipment and improve method of manufacture. At present employed but desires change. D-124.

WORKS MANAGER wishes to make change. Has had more than twenty years' experience, having for the past fifteen years held position as factory or production manager in plants employing from 800 to 1500 men. At present employed. D-125.

MECHANICAL ENGINEER. Technical graduate. Over 20 years' mechanical and executive experience. Now employed. Desires to locate with large manufacturing concern as chief engineer. None but high-class executive position will be considered, where waste and patronage do not prevail but efficient plant operation is demanded. D-126.

ASSISTANT MANAGER or SUPERINTENDENT. Will consider position as chief engineer or resident engineer. Location immaterial. D-127.

DIRECTOR or PRINCIPAL of trade or vocational school. At present director of trade school. Technical education. Twenty years' practical experience in machine work and teaching. Best references. Desires to make change. D-128.

CHIEF ENGINEER. Age 35. Desires position of responsibility with live company, as head of engineering department. Successful in designing with view of low-cost quantity production, interchangeability, etc. Has held present position eight years, in charge of engineering department and drafting office with large corporation in Middle West. Desires to locate where ability counts and greater opportunity for advancement exists. Salary $250 to $300 per month. D-129.

EXECUTIVE ENGINEER. Age 30. University of Wisconsin M. E. graduate. Seven years' experience in industrial plants and consulting engineering, embracing power-plant design and testing; specifications; reports; efficiency in power generation and utilization. Employed at present, but desires change to position with better prospects. Location preferred, Middle West. D-130.

YALE GRADUATE mechanical engineer. Six years' practical experience. Desires to change his position for one with either manufacturing company or consulting engineer. D-131.

SPECIALIST in design of boiler furnaces and boiler-room equipment. Mechanical engineer. Age 42. Twenty years' experience in power-plant design, construction and operation. Would take charge of power-plant-construction work; now superintendent of large power station. Present salary $3,000. D-132.

MECHANICAL ENGINEER. University graduate. Age 34. Ten years' experience in West on contract work, design and superintending construction of industrial plants and varied projects; operation and plant efficiency; plans, estimates and reports, design of special machinery. Now in charge of mechanical and civil engineering work for Western concern, but desires to make new connections. D-133.

STUDENT MEMBER. Bucknell University; graduate '17 in mechanical-engineering course. Three years' practical shopwork;

[illegible] D-134.

MECHANICAL AND ELECTRICAL ENGINEER. Graduate [illegible] years' experience [illegible] in present [illegible] position [illegible] Can produce results [illegible] power plant. Has $40,000 worth of [illegible] anywhere. D-135.

GENERAL MANAGER [illegible] MANUFACTURING EXECUTIVE. Age [illegible] Twenty-two years in various executive [illegible] shop foremanship to vice-president [illegible] in large establish[illegible] Experience [illegible] general, covering foundry and machine [illegible] and [illegible] including engines, turbines, blowers, [illegible] pumps, condensers, miscellaneous machine shop products, [illegible] parts, tools, jigs, gages, etc. Knows men and how [illegible] them. Expert in cost accounting and control. Has done [illegible] travelled extensively at home and abroad. Capa[illegible] charge of large plant. Satisfactory reason for desiring change. Highest references. Available thirty days. Location Philadelphia or vicinity. D-136.

MECHANICAL ENGINEER. Technical graduate, age 39. Twenty years' experience in shop and office on small intricate work, such as guns, type-setting machinery, typewriters, adding machines, and cash registers. D-137.

MANAGING EXECUTIVE. Age 37. Fifteen years' experience in mining, quarrying, and manufacture of gypsum and gypsum products, as purchasing agent, designer, and operating manager. Thoroughly familiar with the business in all branches, especially organization and development of efficient machinery and working forces and value of costs and their application to manufacturing. Desires responsible position with financially responsible concern in same or similar business, in which interest may be attained at later date. Now engaged in consulting work; free for appointment after April 1. D-138.

ENGINEER. Technical graduate, twelve years' engineering and manufacturing experience, combined with business and sales. Opportunity desired where technical training and with good business judgment will be of value. D-139.

FACTORY MANAGER or PRODUCTION MANAGER. Technical graduate, 31, ten years' experience in costs, efficiency engineering and factory reorganization and management. Trained in stopping leaks and increasing output. Reference to several concerns as to ability and results secured. D-140.

COMBUSTION ENGINEER. Age 30, married, technical graduate. Four years' experience in boiler-efficiency work, thoroughly familiar with hand and stoker-firing methods and handling boiler-room labor; anthracite or bituminous coal; former assistant smoke inspector of large city. Experienced in fuel analysis, furnace design and other essentials of boiler-room practice. Location preferred, 100 miles from Philadelphia. D-141.

MECHANICAL ENGINEER. Technical graduate, age 35. Eight years' practical experience in design, construction, erection, testing and maintenance of power-generating and distributing equipment. Fully competent to handle problems in station-betterment work. Can qualify as inspector of apparatus under construction. Has had A1 experience on boilers, turbines, steam, oil and gas engines, condensers and electrical equipment. Aggressive, resourceful and capable. Can furnish best references. At present employed as estimator and sales engineer, but desires larger field of action. Available on short notice. Location immaterial. D-142.

CHIEF ENGINEER. Graduate M.E. Age 35. Now construction and maintenance engineer in charge of construction, maintenance and power departments of large electrically driven dye plant; wide experience in construction and maintenance along both electrical and mechanical lines. Seven years chief engineer Western sugar factory. Four years erecting engineer for manufacturer of large steam turbines. Minimum salary $2750. D-143.

GRADUATE ENGINEER. Will graduate from mechanical engineering in June; two years' practical experience in machine-shop work, some experience in turbine design. Will accept any good position offering advancement. References available. D-144.

WORKS MANAGER or ASSISTANT TO EXECUTIVE. Mechanical engineer, age 37. Technical graduate. Fourteen years' varied experience in design, construction, and installation work, including ordnance, ballistic apparatus, hydraulic machinery and structural steel. Well grounded in the fundamentals of steam and electrical engineering. Thoroughly practical, with executive ability, and not afraid of work or responsibility. Location preferably East or South. D-145.

ASSISTANT PROFESSOR or INSTRUCTOR, if there are possibilities of advancement, in mechanical engineering. Degrees of E.E., M.E. and Sc.D. Six years' teaching experience in two of the leading technical schools and some in power plant work. Will be open for engagement after June 15. Location in or near New York preferred. D-146.

ASSISTANT SUPERINTENDENT, age 25, M. I. T. graduate. Experienced in woodworking and in the design of package conveyors. At present employed. Location preferred, New England. D-147.

MECHANICAL ENGINEER, age 31, married. Technical and practical shop work. Wide experience in testing of materials and equipment for large modern factory. Seven years' work on the designing, testing and installation of valves, fittings and steam specialties. Competent in getting out concise reports and business correspondence. Desires position where ambition and hard work are prime necessities. D-148.

WORKS ENGINEER or ASSISTANT WORKS ENGINEER. Mechanical engineer married, age 32. Graduated from prominent engineering school. Three years' experience in operation, erection and maintenance of large boilers, steam engines, gas engines, piping systems and small steam turbines. Three years' experience teaching mechanical, steam and gas engineering practice. Resourceful, tactful and can handle men. Will start at $2000 per year if with good concern, and there is opportunity for advancement and responsibility. Available July 1. D-149.

MECHANICAL ENGINEER with experience in the design and manufacture of aeroplane motors, also expert tool designer, desires executive position in connection with engineering department. Now employed. Location immaterial. D-150.

TECHNICAL GRADUATE, age 31, experienced as a general machinist in locomotive repairs, gasoline-engine construction, foreman in the motive-power department of a leading railway, draftsman in the manufacture of brass goods, pressure regulators and tools connected with the same, and, in the factory system connected with the latter position, desires to locate with a going concern in the industrial field with aim of developing into a position of responsibility. Other conditions considered. Prefers medium-sized cities of Middle West. D-151.

COMBUSTION ENGINEER, age 34, technical and practical. Ten years' experience in combustion and boiler-house efficiency. Familiar with large and small boiler-house practice, different types of boilers and stokers. At present employed by large concern, having produced their best results. Desires a change. Would like to connect with firm having large boiler house or chain of boiler houses requiring the services of a progressive man. Highest references. D-152.

MECHANICAL ENGINEER. Technical graduate with ten years' experience as draftsman and superintendent of construction desires position where his four years' railroad shop training and knowledge of works management will be of value. D-153.

MECHANICAL ENGINEER, age 25, technical graduate. Has machine-shop and drafting experience, knowledge of accounts and up-to-date efficiency methods. Desires position as assistant to executive or works manager. Successful experience as executive. Now employed. D-154.

POWER ENGINEER or FACTORY MAINTENANCE ENGINEER. Technical education and six years' experience in gas, oil, and steam plants, light, heat and power transmission, factory upkeep and extensions. At present employed. D-155.

ASSISTANT PROFESSOR in mechanical engineering or electrical engineering or similar position as supervising technical instructor. Graduate M.E. from one of the leading engineering universities. Eight years' experience in teaching engineering subjects. D-156.

MANAGER, ASSISTANT, SUPERINTENDENT, EXECUTIVE or SALES ENGINEER. Technical graduate in mechanical engineering; varied experience in mechanical, electrical, and civil engineering lines, involving design, inspection, reports, responsible charge of construction work, plant operation, management, purchasing, etc., in connection with power, lighting, and industrial plants, electric railways, etc. Salary $3,000-$3,600.—D-157.

ENGINEERING SURVEY

A Review of Engineering Publications in All Languages. All the leading periodicals of the engineering world, embracing over 1000 different publications, are received at the Library. These are systematically examined for review each month in the Survey.

SUBJECTS OF ABSTRACTS

Arranged in the Order of Their Appearance in the Survey

One of the most significant movements brought about by the European War is an intensification of scientific and engineering research. The reasons for this are fairly obvious. In the first place, it is due to the effort to satisfy the tremendous demand for war materials and necessities of life, where the supply of the latter has been interrupted. In the second place, the search for new ways and means of production is caused partly by the desire to make the country independent of foreign supply of basic essentials of manufacture; and further, it expresses the effort to pay the cost of the present struggle by a production increased in volume and more economical in method.

In the present issue, this tendency is exemplified by the article of Le Chatelier on Scientific Problems Awaiting Solution.

THIS MONTH'S ARTICLES

In the section Aeronautics attention is called to a description of sand-load tests on wings of a Curtiss flying boat.

Data on the structure of the coating of tinned sheet copper, in relation to a curious case of corrosion of this material, are reported from a Technologic Paper of the Bureau of Standards, of which an advance abstract has been courteously supplied to The Journal by the Bureau.

At Queens University, Kingston, Ontario, an investigation on cobalt alloys with non-corrosive properties has been carried out.

Also from an advance publication of the Bureau of Standards is reported a description of a specific-gravity balance for gases.

The limits of inflammability of gaseous mixtures form the subject of an investigation by Prof. W. M. Thornton, abstracted from the (British) *Philosophical Magazine*.

The engineering phases of smoke abatement are discussed by Osborne Monnett, who considers draft as by far the most important factor in the question of reducing smoke effectively.

An editorial in a British publication, *The Auto*, reports a discussion at the Midland Institute of Mining Engineers, Birmingham, England, on the use of benzol as a fuel in Great Britain after the War. The discussion is of particular interest because it covers the question of distribution as well as the more strictly technical features of use.

In the section Hydraulics will be found a description of a California water-power installation, claimed to constitute a record for low-head development. Its turbines are so designed as to handle hydraulic heads of but 8 ft. In this description particular attention is called to the design of the sliding-jaw clutches and the oil-pressure governor.

From the *Cornell Civil Engineer* is briefly abstracted a paper, by G. C. Brown, entitled Some Notes on Stream Flow. In addition to the information reported in the abstract, the paper contains highly interesting passages which could not be reported on account of lack of space.

Experiments carried out at Purdue University on carburetor performance have been reported by Prof. R. C. Berry in a paper before the Society of Automobile Engineers. They present coördinated data on the performance of the carburetor proper, apart from that of the engine, and show clearly the variation of output and efficiency of the engine as functions of fuel consumption.

A novel type of combustion engine invented in this country by R. M. Hvid is described by E. D. Blakely. While it works essentially on the same principle as the Diesel engine, its cycle is rather different from the latter.

The Railroad Engineering section contains three articles of interest. The question of superheat in locomotives is treated in an abstract of the discussion at the last convention of the American Railway Master Mechanics' Association.

A description of the application of Mogul running gear and machinery to a Mikado locomotive is taken in abstract from the *Railway Mechanical Engineer*.

From a paper by [illegible] Fowler are abstracted some [illegible] water conditions in the locomotive boiler which [illegible] [illegible] depend on the analysis of the raw [illegible] to determine the conditions prevailing [illegible] boiler.

[illegible] contain two articles de[illegible] subject, viz., power generation [illegible] Wilson describes the Ford [illegible] boilers. The editorial [illegible] devoted to the description [illegible] Company, presents data on [illegible] plant for 200,000 kw. capacity, in [illegible] kw., using pressures and superheats [illegible] ago would have been deemed practically [illegible]

Aeronautics

Sand Load Tests on Wings of Curtiss Flying Boat H-12, John H. DeKlyn and G. E. Hawthorn

The tests described here were conducted at the order of and according to the standard instructions of the British Admiralty. The wing was the largest ever tested in this country, the overall span being 92 ft. The wing on but one side of the boat was tested.

The loading required is given by the formula:

$$P = N(W + W_1 - W_2) - W$$

in which P = weight of sand on wing surface; N = required factor of safety; W = net weight of machine; W_1 = useful load carried, including gasoline, pilot, passenger, and any other useful load; and W_2 = weight of wings. The total load applied was 28,110 lb., of which the upper plane carried 69 per cent, or 19,400 lb.; and the lower plane 31 per cent, or 8700 lb.

As a result of the test (fully described in the original article) it was found that the wing withstood the load specified by the Admiralty instruction without permanent deflection or signs of failure.

An illustration of the strength of the wings is afforded by the fact that the wing was tested with a load of sixty people, amounting to 9930 lb., which is, however, only about half the maximum load. (*Aviation and Aeronautical Engineering*, vol. 2, no. 3, March 1, 1917, pp. 136-137, 2 figs. *c*)

Note on Stresses in Built-up Rectangular Bodies Due to Rudder Forces, Alexander Klemin and W. B. Ford

The article discusses the stresses in a body produced by a rudder when its center of pressure is fairly high above the center line of the body. In this case the wire and longeron stresses induced by the forces of the rudder are worked out for a single panel of a typical rectangular body, assuming the stabilizer to be 35 sq. ft., the elevator 11 sq. ft., the rudder 8 sq. ft., and the vertical fin 45 sq. ft., in area.

The rudder forces produce, first, bending in a vertical plane through the middle of the aeroplane; and second, twisting about the axis passing through the centers of the transverse diagonal wires in any panel. To allow for bending, it is sufficient to divide the rudder load equally between the upper and lower planes of the body, and to draw stress diagrams in these planes in the usual manner. A process is indicated to allow for twisting.

The article presents complete computations for one panel of a body under rather severe air-load conditions; these computations including also the landing stresses. The data are presented in the form of a table, showing, among other things, that the effect of the rudder loads is by no means negligible; while the air loading assumed (speed 100 miles per hour; rudder of 7 sq. ft. area, turned at 20 deg. simultaneously with stabilizer at 6 deg. and elevator at 20 deg.) is rather severe, it may well occur after a steep dive. In such an event the factor of safety would be considerably smaller than that which would follow from the ordinary calculations under Army specifications. Incidentally, it is shown that the stresses due to landing are sometimes of lower and sometimes of greater value than those obtained from the combined air loads, showing the advisability of carrying through both air- and landing-stress calculations. Engineering Materials

The Structure of the Coating on Tinned Sheet Copper in Relation to a Curious Case of Corrosion of This Material, Paul D. Merica

The attention of the author has been directed to a curious and instructive case of local corrosion or pitting in tinned sheet-copper roofing. The pits occur in general along the line of surface scratches, having appeared some eight or ten years after completion of the roof. These pits are apparently unrelated to the service conditions and to the direction of rolling of the sheet.

A study of the structure of tin coating on copper has been made, and has shown that this coating consists of at least three layers, viz., a thin layer of Cu_3Sn immediately next to the copper, then a layer of Heycock and Neville's constituent N, containing about 60 per cent by weight of tin, and, finally, a layer of the eutectic of tin and copper, in which is found most probably also the lead when it is present in the tinning mixture. This coating in the case of the corroded sheet was thin, averaging about 0.012 mm. in thickness, and quite variable in both thickness and structure, varying from 0.006 mm. to 0.03 mm. in thickness. At many points there were breaks in the continuity of the alloy layer; at others, breaks in the continuity of the eutectic layer.

Etching experiments and measurements of electrolytic e.m.f. of these layers towards various solutions, such as water, dilute acids, and acids to which ferric or stannous chlorides had been added, showed that the constituents of these intermediate alloy layers are more electronegative, i.e., less corrodible than either the tin or the copper. Values were found for the e.m.f. of these alloy constituents against copper in various solutions varying from — 5 to — 80 millivolts.

When the copper becomes exposed, therefore, as in the present case at the bottom of the scratches on the surface, it forms together with the alloy layer a galvanic couple, electrolytic action sets in, and the copper at these points is corroded, forming the pits described.

Many instances are known, of course, of roofs of such material which have been in service for twenty or more years, under severer conditions as regards soot, smoke, etc., than were those under which the roofing in question failed, and which nevertheless have not shown signs of such pitting. Explanation of this variation in service rendered by different samples of the same type of roofing material must be sought in the variation of mechanical abuse, such as scratching, which it receives, and also in the uniformity of structure and thickness of the tin coating. (Abstract of *Technologic Paper No. 90*, Bureau of Standards, Washington, D. C., July 11, 1916.)

COBALT ALLOYS WITH NON-CORROSIVE PROPERTIES, Herbert T. Kalmus and K. B. Blake

Data of an investigation conducted at Queens University, Kingston, Ontario, for the Mines Branch of the Department of Mines, Ottawa, with a view to determining the use of cobalt as an inhibitant of corrosion.

The main purpose of the present investigation was to determine the effect of the addition of small quantities of cobalt on the atmospheric corrosion of iron and mild steel—in particular, very pure iron prepared by the open-hearth method for sheet roofing material.

The comparative effects of small amounts of cobalt, nickel, and copper were studied.

The experiments cannot be considered as conclusive, partly because of the methods used and also because no heat treatment was given to the alloys. But from these premiminary experiments it appears that additions of small percentages of either cobalt or nickel to very pure ingot iron add to its non-corrosive properties. When used in like amounts, cobalt seems to be more effective than nickel.

It was also found that the rust on the cobalt samples is more tenacious than that on the other samples, and particularly that it is of a much darker color and is removed by mechanical means with very much greater difficulty than the rust formed on very pure ingot iron containing no cobalt. In this connection it has also been found that annealed samples differ from unannealed in that for the annealed samples the rust is light in color and much more readily removed than in the case of unannealed ones.

In addition to ordinary corrosion tests with long exposure, a few accelerated corrosion tests were made on some of these alloys. These tests, which must be considered as only preliminary, would indicate that the addition of monel metal to American Rolling Mill Company ingot iron to the extent of about one per cent produces a more non-corrosive alloy for sheet roofing materials than the addition of similar small percentages of cobalt.

It has also been found that the addition of copper to American ingot iron to an extent between 0.25 and 0.75 per cent seems to be conducive to reducing the corrosion of this quality of iron under atmospheric conditions. It is difficult to say, however, whether or not the addition of copper in these amounts has a greater or less effect than the corresponding amounts of nickel or cobalt. Fuel and Firing

ENGINEERING PHASES OF SMOKE ABATEMENT, Osborne Monnett

The writer states that if he were to answer the question: What are the three most important things in smoke abatement? he would be tempted to say: first, draft; second, *draft;* and third, DRAFT.

In investigating the smoke problem in Chicago, where he was formerly Chief Smoke Inspector, it was found that draft was so important as to overshadow every other consideration; and through a long series of investigations covering some thousand separate and distinct studies of boiler settings, the curve was developed (Fig. 1) which tells how much draft is needed for different rates of combustion. Roughly, the rule is this: We need 0.1 in. draft over the fire per pound of coal burned per square foot of [illegible] tells the story almost entirely [illegible] of the curve. Beginning with 0.15 in. per [illegible] fire, we are able to burn 15 lb. coal per square foot [illegible] surface per hour smokelessly. Cases can be cited [illegible] burned, but not smokelessly.

The limit rate of successful smokeless combu[illegible] fired units is about 28 lb. coal per square foot of grate surface per hour.

The rate of combustion in any plant is fixed, first, by the load. When the load is known, the ratio of grate surface to heating surface has to be fixed. These two factors decide the rate of combustion, and with these the curve will show how much draft is needed over the fire.

In laying out a stack it is necessary to know how much draft loss there is in the particular type of boiler setting selected, so as to know the proper amount of draft over the fire to be provided. This loss runs from 50 to 65 per cent of the draft available at the stack side of the damper. For

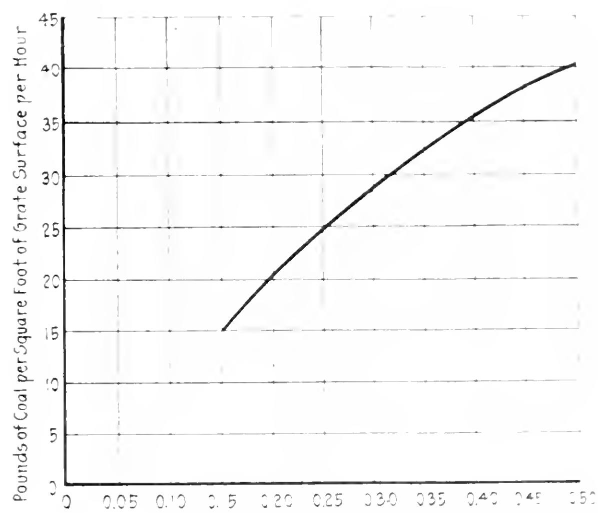

FIG. 1 DRAFT FOR SMOKELESS COMBUSTION

determining the height of stack the author recommends the Stirling formula.

In studying the smoke problem in Chicago, it was realized that it would be necessary to develop some type of hand-fired furnace that could be operated within the smoke limits. After several designs had been tried, they came to flush-front Dutch-oven settings. These settings, however, made more smoke than the standard Hartford setting. The reason for this is supposed to be as follows: When high-volatile coal is thrown on a fire, there is a normal distillation of volatile matter due to the heat of the firebrick. But when you throw coal on a fire with a Dutch oven, there is not only the normal distillation of volatile matter, but in addition an artificial distillation due to the high temperature of the heat radiating from the red-hot firebrick over the fire, resulting in a double distillation of volatile matter. This causes dense smoke in spite of all efforts to prevent it.

By taking off the brickwork over the fire the rate of volatile distillation was reduced, because there was no radiation of heat from the red-hot firebrick. This not only gave a smokeless furnace, but also increased the steaming capacity of the boiler, because there was a direct radiation from the grate into the boiler.

The next problem discussed in the paper is that of burning coal at lower rates of combustion. Here, after a long evolution, we have come to a down-draft boiler with a water-cooled grate, which, if properly handled, is smokeless. (*Proceedings of the Engineers' Society of Western Pennsylvania*, vol. 32, no. 9, December 1916, pp. [illegible]-295, 10 figs. *dp*)

Benzol After the War

The demand for explosives created an enormous increase in the production of benzol in Great Britain. A certain amount of this product and of toluol, which is produced side by side with benzol, will be required for dyes, even after the cessation of hostilities, but a market will have to be found for the excessive production, or approximately forty million gallons of benzol per year.

W. Newton Drew touched upon this question in his paper on The Rectification of Benzol, recently read before the Midland Institute of Mining Engineers, Birmingham, Eng. He expressed the opinion that this excess of benzol will have to be sold as a motor spirit to take the place of gasoline. To make this possible, the benzol must be of standard quality as regards distillation tests, purity and dryness, and must be easily obtained everywhere in convenient form, and at a standard price.

While nothing has been done as yet to prepare for this emergency, the speaker urged that the by-product installations of each district throughout the country should be linked up in some association or associations outside thé coal and coke industries.

As regards the advantages and disadvantages of benzol as motor fuel, the President of the Institute, C. C. Ellison, remarked that he was one of the first to use benzol in cars, but had to give it up because of its objectionable smell. Since then, however, improvements in washing it have progressed so far that now a very good spirit is obtainable.

W. Newton Drew pointed out that 90 per cent of benzol contained approximately 84 per cent benzene, 15 per cent toluol, and 1 per cent xylene, and that standard benzol consisted of 96 per cent benzene and 4 per cent toluol. It is important to bear in mind that a small addition of toluol is not only not an adulterant, but has proved of great benefit in that it increases the calorific power of the fuel, and in winter it prevents its freezing. (Editorial in *The Auto,* vol. 22, no. 6, 840. February 9, 1917, pp. 92-93, *g*)

Vertical Furnaces

A furnace has been recently completed to a Government order in England by the Monometer Manufacturing Co., Ltd., Birmingham, in which a novel method is used.

The problem was to have several long tubes heated uniformly throughout their length to a red heat, the temperature to be kept constant within small limits. This was effected by supporting the tubes in a vertical position in the furnace and applying automatic heat control. Several rings or series of burners are arranged round the furnace at different heights in order to obtain a uniform distribution of the heat, a muffler or protection tube being interposed between the burners and the tubes to be heated in order to prevent heat from impinging directly upon the inner tubes. By this means the temperature throughout the periphery of the furnace as well as the height of the furnace is made uniform.

One control is provided for each ring or series of burners. The control operates on the thermostatic principle and is adjustable to suit the temperature desired. (*Aeronautics,* vol. 12, no. 170, January 17, 1917, p. 55, 1 fig. *d*)

Gas Engineering

A Specific-Gravity Balance for Gases, Junius David Edwards

The need for an accurate method of determining gas density has been especially urgent in the natural-gas industry, where the measurement of gas by means of orifice meters requires a knowledge of the density of the gas. An investigation by this Bureau of the effusion type of apparatus, which has been generally used for this purpose but which has proven unreliable in practice, has shown the need of more precise methods. To supply this need the present method was adopted and suitable apparatus designed.

The principle of the method employed is based upon the laws of the compressibility (Boyle's Law) and the buoyant effect of gas. The balance contains a beam which carries on one end a relatively large globe and on the other a small counterweight; the beam is enclosed in a gas-tight chamber. The buoyant force exerted upon the globe is proportional to the density of the gas and therefore to its pressure. Therefore, if the buoyant force exerted upon the globe is made the same as shown by its position of equilibrium when it is suspended successively in two different gases, then the densities of the two gases must be the same at these pressures, or the specific gravity is the inverse ratio of the pressures. In operation the balance case is filled with air and the pressure adjusted until the beam balances. It is then filled with gas and the pressure required to secure a balance is determined in the same way.

The apparatus described provided a quick, accurate means of determining gas density. The balance beam is supported on two needle points, which give high sensibility. The needles are easily adjustable and in contrast with the metal or quartz knife edge usually used can be obtained almost anywhere, are inexpensive, and can be replaced as often as necessary. The success obtained in the use of this apparatus is mainly due to the high sensibility afforded by this means of support. It is necessary to remove the beam from the case only when it is desired to transport it. No leveling bottle is necessary in adjusting the gas pressure within the balance, this being accomplished by means of a needle valve which affords precise control. A portable outfit is described which combines lightness of weight, convenience in use, and durability without any great sacrifice in accuracy. No preliminary calibration of the apparatus is necessary. The results obtained with this balance were compared with those obtained by a direct weighing method and it was shown that an accuracy of one or two parts per 1,000 could be obtained quickly and without elaborate precautions. (Abstract of *Technologic Paper No. 89,* Bureau of Standards, Washington, D. C.)

. Gas Gate Valve, D. E. Keppelmann

Gate valves depend upon a disk or disks riding into a groove between two seats for their tightness. As a rule, leaks develop either because of accumulation of foreign matter in the valve or through the scoring of its disk or seats by the pressure.

In fact, the groove in the bottom of the valve acts as a constant trap for deposits of foreign matter. If the groove has been filled with foreign matter, however, it becomes finally impossible to lower the disk, which causes leaks.

The valve described in this article does away with this difficulty by eliminating the grooved trap. The opening and closing feature consists of a solid wedge with the port constantly riding on its seats located in the sides of the valve, creating a clean opening through the valve. This makes the valve self-cleaning, for with the valve open it presents a clean surface flush with the body of the valve. Consequently the foreign matter rides through since there is no trap or groove or restriction of any kind for the accumulation of foreign matter, making it possible at all times to close the valve whenever necessary. When the valve is closed the foreign matter will accumulate against the wedge, and simultaneously with the lifting of the wedge this accumulation is immediately cut from the wedge and carried through the valve by the liquid or gaseous substances in the line.

An additional advantage claimed for the new valve is that no by-pass is necessary to equalize the pressure on both sides of the disk before the latter has been raised, for the seats are never exposed to the elements passing through. Hence scoring is impossible and leakage from this source is eliminated. (*The Gas Age*, vol. 39, no. 3, February 1917, pp. 121-123, 6 figs. *d*)

The Limits of Inflammability of Gaseous Mixtures. Prof. W. M. Thornton

The ignition of an inflammable gas mixed with air depends in a variety of ways upon the proportion of oxygen present. With impulsive sparks or condenser discharge the ignition passes through critical stages when the ratios of the number of oxygen atoms to one molecule of gas are whole numbers. The writer shows that the proportions of oxygen in a limiting mixture are in regular systems.

Burgess and Wheeler have shown that in the case of the paraffins the lower limit of inflammability is inversely proportional to the calorific value of the gas. But this is also the case when the number of oxygen atoms in the limiting mixture bears the same proportion in each case to those required for perfect combustion. The present paper is devoted to an examination whether in general the proportion of oxygen in the limiting mixture has any direct relation to that for perfect combustion. The author finds that in the upper-limit mixtures of the paraffins there is twice the volume of inflammable gas there is in the mixture for perfect combustion, and that, further, the ratio of the upper to the lower limits of inflammability should be nearly constant. He points out that while the upper and lower limits of inflammability can be considered as controlled by the heat liberated in the reaction, it is not the heat set free that controls the oxygen that can be present (and so decides the percentage of gas), but the oxygen that controls the heat. Hence inflammation can only occur when certain numerical relations exist between the oxygen and gas molecules. From this the author derives certain data from which may be predicted the limits of inflammability of certain groups of compounds with fair hope of accuracy. (*The London, Edinburgh and Dublin Philosophical Magazine and Journal of Science,* vol. 33, no. 194, February 1917, pp. 190-196, 1 fig, *et*)

Heating

Relative Economy of Heating by Steam at Different Pressures. A. Bement

Recently in Chicago tests were made to determine the relative cost of heating with steam at atmospheric pressure as against 3 to 5 lb. pressure in modern office building plants.

In an analysis of the problem a heat requirement of 5000 B.t.u. per hour was taken. On the whole it appears that there is no appreciable difference in cost of heating at different pressures. There is, however, an advantage in higher pressure from the standpoint of first cost of plant because as the pressure is greater the plant may be smaller. This factor, however, has a limited value in practice unless excessive pressures are used. As a matter of fact, any plant designed to work at 5 lb. should have margin enough to work perfectly at atmosphere, and vice versa, so that in the end the cost of heating will be identical in both cases. (*The Heating and Ventilating Magazine,* vol. 14, no. 2, February 1917, pp. 27-29, *ce*)

Hydraulics

A New Record for Low-Head Development. Rudolph W. Van Norden

Description of an unusual water-power installation of great interest in that the turbines are so designed as to handle hydraulic heads of but 8 ft. The installation was built by the labor of the convicts at the State Prison, Folsom, Cal., and it is stated that the work was free from accident. The prison is situated two miles east of Folsom, on the south side of the American River, tributary to the Sacramento, having its source among the high altitudes of the Sierra Nevada range. For about nine months in the year there is sufficient water in the American River to operate the Pacific Gas & Electric Company's plant at the end of the canal line. During the remainder of the year the river's flow dwindles until in most years it will not exceed 100 cu. ft. per sec. With a canal full of water flowing, and the water level above the prison plant at the spillway line, the difference in water level above and below the prison power house is actually 8.5 ft. During the period of low-water flow the tail-water level falls until the difference in head may be as great as 12 ft. In other words, a variation in head on the turbines may be almost as great as 50 per cent of the normal head. It was required to supply a plant which would deliver continuously not less than 400 hp.

A runner design for high specific speed and consequent great water capacity was essential, and one was adopted of 51 in. mean diameter, operating at 100 r.p.m. and having a nominal shaft horsepower of 215 while operating under 8.5 ft. head with a flow of 285 sec-ft. The design of the turbine was such that while the power output increases more than 50 per cent when the head is increased to 12 ft., the efficiency also increases several per cent.

All machinery is driven by induction motors.

The total weight carried by the thrust bearing is 19,000 lb., to which must be added a hydraulic thrust on the runner of 6000 lb., making 25,000 lb. total load. The two vertical steady bearings are oiled from a glass cup having a capacity of 0.6 gal. of lubricating oil. To prevent the oil following the shaft after passing through the bearing, there is provided between the lower end of each bearing and the annular cup a baffle ring which solidly clamps the shaft, thereby deflecting the oil into the cup.

A horizontal jackshaft extends between the vertical shafts of the two turbines and runs at 300 r.p.m. Upon each end of the jackshaft is mounted a rawhide bevel gear driven from the turbine shafts by cast-iron bevel gears having split hubs mounted on the turbine shaft. As it is intended to drive the

quickly from either turbine but not from both at one time, there are two sliding jaw clutches operated by levers which extend above the generator floor. In the design of these jaw clutches, the following problem had to be solved. In throwing out one clutch in order to engage the other, with both turbines running, it must be possible to momentarily engage the idle clutch before disengaging the running clutch. The generators operating in synchronism, there are 36 points of relative position between the two rotors, any one of which may take place when the machines are synchronized. As the bevel gears have a ratio of three to one, there are 36:3 = 12 positions in a jaw clutch when the two halves of the clutch might engage. In order that the incoming clutch may always be in a position to engage, the jaw clutches are built with twelve radial jaws. The object of the jackshaft was to furnish by belt drive the power to drive the exciter, the governor head and the oil pump furnishing oil under pressure to operate the governor.

One oil pressure governor controls both turbines. It is so arranged that both turbines may be controlled by the governor or one turbine by governor and one by hand, or both by hand. The governor proper stands on the station floor midway between the two generators, the operating cylinder being horizontal and close to the floor. The piston rod of the operating cylinder extends through both heads. Close to either generator and in line with the direction of motion of the governor are the two handwheel mechanisms, which are mounted on a cast-iron frame that carries the crosshead into which the piston rod is fastened: an arm of this frame, which is flush with the floor, carries at its extremity a ball thrust bearing, and passing down through the arm and supported by the thrust bearing is the rotating gate shaft which operates the turbine gates through push-and-pull rods at the lower end of this shaft. Above the thrust bearing and keyed to the gate shaft is a bell crank, and this is operated through two links from the crosshead. The handwheel is on top. Its vertical shaft carries a spur gear which engages a pinion for the purpose of a gear motion reduction. The pinion shaft carries another pinion which engages a rack on the back of the crosshead. The handwheel rigging is contained in a housing integral with the main frame, but is mounted on an eccentric which is moved by a lever fitted with a hand pull. By this means the handwheel mechanism may be thrown out of gear with reference to the crosshead. On the handwheel shaft is a brake operated by a small crank. The piston passes through the crosshead freely, but engages the crosshead by means of a spring bolt operated by a swinging handle. While governing, the spring bolt is in and the handwheel mechanism by means of the eccentric is entirely out of gear. When operating by hand, the pin is pulled out and the eccentric thrown in, and the brake is used to hold the handwheel where desired. The turbine gates are designed to be so balanced as to have an opening tendency up to 0.4 load and a closing tendency above this point. While the gates and mechanism are heavy, one man can handle the gates without difficulty, while the governor moves them easily with an oil pressure as low as 60 lb. (*Journal of Electricity*, vol. 38, no. 3, February 1, 1917, pp. 65-69, 6 figs, *d*)

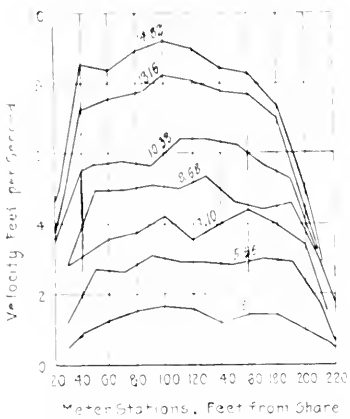

FIG. 2 SURFACE VELOCITIES FOR EACH 20 FT. STATION

SOME NOTES ON STREAM FLOW, G. C. Brown

While taking current-meter readings in the Beaver River at Newport, Pa., a certain measurement was about three-quarters completed when the meter refused to tick off the revolutions. Eight sections had been measured and the stage of the river was such that it was highly desirable to have a reading at that point. Accordingly, the discharges for the eight stations measured were computed for stages just above and below the one under consideration, and also their ratio to the respective total discharges. The results proved to be surprisingly alike, and this prompted a more thorough investigation of the relations that might possibly lie hidden in the field notes gathered from that same stream.

The Beaver River is a stream of no unusual characteristics. A cross-section of the river where the current-meter measurements were taken shows a stream with fairly uniform sand and gravel bottom paved with hand-laid rip-rap on one bank and having a natural dirt slope covered with weeds and brush on the other bank.

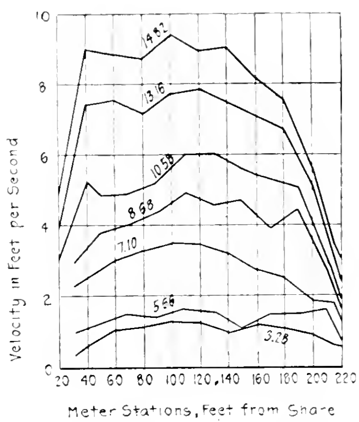

FIG. 3 MEAN VELOCITIES FOR EACH 20 FT. STATION

Gage height 3.28 indicates a very low stage of the river and 14.28 a high flood stage. It might naturally be supposed during this wide variation in height, velocity and discharge that increased cross-current eddies and other disturbances would so confuse the natural line of flow in the stream that no similarity could possibly exist in the curves of low and high stages. It is a surprising fact, however, that marked relations do exist. Fig. 2 shows the surface-velocity curves at each 20-ft. station for different stages. While there are marked variations in some of the curves, there is also a great similarity among them all. The same likenesses, but in greater degree, are seen in the curves of mean velocity given in Fig. 3. The curves of discharge in each 20-ft. section show a more marked similarity. The effect of the difference in roughness between

the paved slope and the natural-earth slope is very clearly indicated in each set of curves. The section of deepest water and freest flow is also indicated by a high point in the curves.

Other curves show that the discharge in any 20-ft. station of the stream for any given stage bears a certain relation to the total discharge for the same stage, and nearly the same relation holds true whatever the stage of the river. For sections outside of approximately the middle third of the stream, the ratio of discharge in any section to the total discharge is nearly constant, except for very low stages.

In the main body of the stream, where the conditions of flow are such that the effect of friction is practically constant, the mean velocity of all sections is increased to the same fold for any change in state when the form of the curves showing this relation remains almost constant.

The paper is of particular interest in showing how an intimate study of a single discharge section of a river brings out the interesting features of stream-flow measurements. (*The Cornell Civil Engineer*, vol. 25, no. 4, January 1917, pp. 161-169, 5 plates, *et*)

Internal-Combustion Engineering

New Rotary-Valve Engine Design

Description of the Van Keuren mono-valve engine which is about to undergo tests in one of the Detroit laboratories. It

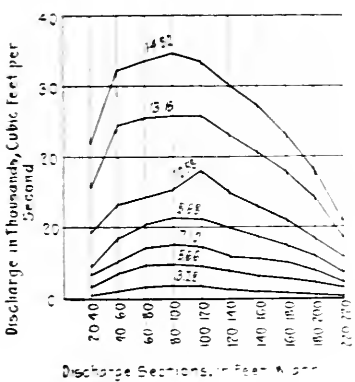

Fig. 4 Discharge for Each 20 Ft. Station

is of interest because of its use of an overhead rotary valve. The difficulty hitherto has been of properly cooling the valve, with the result that warping soon occurred and the engine failed. In this particular engine the cooling water is free to circulate through the entire length of the overhead cylindrical valve. The valve is lubricated by mixing the oil with the gasoline in the proportion of about 1 pt. of oil to 5 gal. of gasoline.

In this engine the cylinder block is suspended over the valve cylinder. In this way all upward reactions are transmitted to the valve and the valve operates under about 60 lb. maximum pressure per square inch of bearing area. The purpose of this is to allow the cylinders to seat upon the valve members and maintain gas tightness in the cylinder ports. In other words, the seating is directly opposite to that of the poppet-valve type, as the cylinders are brought to their seat inside of the valve. To eliminate the carbon troubles which have also been prevalent on overhead-rotary-valve engines, the valve is so shaped as to scrape the carbon from the seat as it is formed.

Another feature of an engine of this type is the possibility of obtaining proper combustion-chamber [illegible] In this case the chamber is conical and machined all over. The spark plug at the side fires directly into the charge. ([illegible] *Automobile*, vol. 36, no. 8, February 22, 1917, p. 412, 1 [illegible])

The Hvid Engine, E. D. B[illegible]

Description of an oil engine invented in [illegible] by R. M. Hvid and working on a cycle approaching that of the Diesel engine.

The engine is of interest because of the wide variations in fuel which it is able to use. The writer claims to have actually run a Hvid-type motor on the following fuels: kerosene, crude oil, fuel oil, road oil (35 per cent asphaltum), cod-liver oil, castor oil, lard oil, cylinder oil, melted butter, and thick cream. It is not claimed of course that all these fuels could

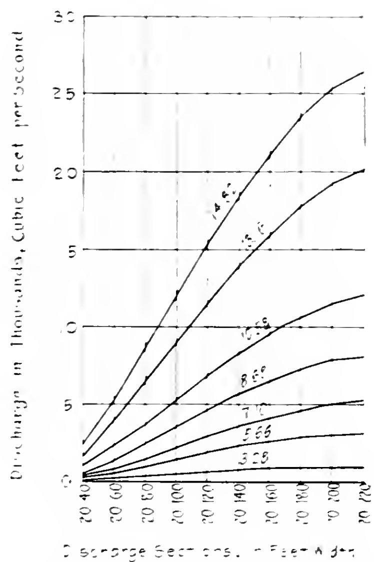

Fig. 5 Total Discharge Progressing Across Stream

be used practically, but the fact that the engine will run on them speaks for the principles involved.

The Hvid-type motor may be made either four-stroke or two-stroke cycle. Ignition is secured by the heat of compression, but unlike the Diesel motors the Hvid motor requires no air compressor.

Fig. 6 is a cross-section of the Hvid injector valve, the extreme end of which projects into the combustion chamber and operates as follows:

On the suction stroke of the motor, pure air only is admitted to the cylinder through the inlet valve 1. While this air is being drawn into the cylinder, the fuel valve 2 is mechanically opened and some fuel flows out of a hole 3 into a steel cup 4, the amount of oil being controlled by the needle valve 5. The fuel valve 2 closes again just before the end of the suction stroke and seals hole 3. The compression stroke follows next and the air previously admitted to the cylinder is compressed to about 450 pounds per square inch, which renders it incandescent. The compression pressure enters cup 4 through holes 6 at the bottom of the cup, and a minute amount of the oil lying at the bottom of the cup is ignited by the incandescent air. The combustion which takes place gives rise to a pressure within the cup far in excess of the compression pressure in the cylinder, and the oil lying at the bottom of the cup is forced out of cup 4 through holes 6 into

the incandescent air in the cylinder, where it ignites spontaneously, the pressure arising from combustion forces the piston forward on the working or expansion stroke.

The Hvid cycle is as follows:

First, a charge of pure air is drawn into the cylinder at or near atmospheric pressure and temperature. During part of this suction stroke, fuel is admitted by gravity through a mechanically operated valve into a small steel cup, the inside of which is connected with the main cylinder by two small pinholes which are located at the bottom of the cup and point toward the piston. The amount of oil admitted is controlled by the governor by means of a needle valve.

Second, the pure air in the cylinder is compressed to between 400 and 500 lb. per sq. in., which gives rise to temperatures of from 950 deg. to 1050 deg. fahr.

Third, as the temperature of the air in the cylinder rises, due to compression, so does the temperature of the small amount of air which is in the steel cup, since the cup is connected by the two small pinholes with the main cylinder. There ensues then within the cup an ignition and combustion of a very small amount of the oil previously admitted to it.

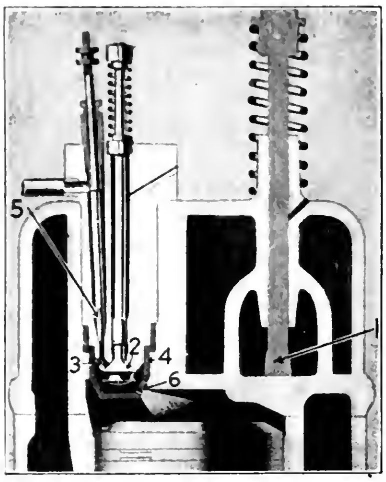

Fig. 6. Cross-section of the Injector Valve of the Hvid Engine

(The amount of oil consumed by this preliminary or primary combustion within the cup must necessarily be infinitely small because there is not sufficient air in the cup to support the combustion of more than a minute amount.) As this combustion takes place, the pressure within the cup rises above that in the combustion chamber and drives the surplus oil out through the two pinholes in a heated spray, which, on coming in contact with the hot compressed air in the cylinder, ignites and burns at approximately uniform pressure.

Fourth, the products of combustion are exhausted. The cycle is then repeated.

It is stated that recently a test of a three-cylinder Hvid-type engine was made in Lansing, Michigan. The same size of engine operating as a conventional type of gasoline engine was rated at 60 hp., with a maximum output of 70 hp., but when converted into a Hvid type it showed a maximum output of 87 hp. and was rerated at 75 hp. The fuel consumption during this test with fuel oil as fuel was 0.42 pint per hp. The complete log of the tests is not given. It is also stated that the Hvid type can be built in units as small as 1 hp. (*Motor Boating*, vol. 19, no. 1, January 1917, pp. 25, 56 and 58, 2 figs., *d*)

A Standard of Carburetor Performance, Prof. R. C. Berry

Carburetor performance is often reported in terms of engine performance. This may serve the purpose when it is desired to compare the merits of different carburetors for use on a good engine, but it does not throw much light upon the performance of the carburetor itself. There ought to be established a standard of carburetor performance that would be expressed in terms of the ability of a carburetor to perform those functions for which it was designed.

The best carburetor is the one maintaining a sufficient volume to atomize the fuel properly, and at the same time adding just enough heat to gasify the mixture. The amount of vacuum required will depend partly upon the scheme used in atomizing, and partly upon the character of the fuel. The amount of heat required will also depend partly upon the way in which it is applied, and partly upon the character of the fuel.

Some experiments have been recently carried out in the laboratories of Purdue University, on a Haynes "Light Six" engine mounted on a Diehl electric dynamometer. The paper reports in detail the methods used in the tests. Curves similar to Fig. 7 were drawn in each case. In this figure the vertical (at 0.0671 lb.) represents the theoretically perfect mixture of fuel and air, or the one in which there is just enough oxygen in the air to burn the fuel, and no excess of either fuel or air. The curve shows that the engine will run with a *mixture* of less than 0.055 lb. of gasoline per pound of air, but will not pull well with so lean a mixture. As more fuel is added, the power will increase rapidly until nearly full power is reached, when the curve becomes almost horizontal, increasing slowly to a maximum, then decreasing slowly for a time but finally reaching a point where it falls off rapidly.

The richest mixture with which the engine could be run was 0.155 lb., or nearly three times as rich as the leanest mixture. In other words, a carburetor can be adjusted with as lean a mixture as can be used to carry full load, and the amount of gasoline can be nearly doubled without greatly affecting the power capacity of the engine. It is practically impossible to stand by the side of an engine mounted on a test block and distinguish any difference whatsoever in its performance as the mixture is being changed through this range. But the effect of this change upon the *efficiency* of the engine is very different. The point of highest efficiency seems to coincide almost exactly with the point of the theoretically perfect mixture. As the mixture is made richer than this the efficiency will decrease, even while the power is increasing slightly, and will decrease rapidly after the point is reached where the power is also decreasing.

Another set of curves given in the article shows that the mixture for maximum power is not noticeably affected at *half-load* by the speed, but that at high speeds the engine cannot hold up its power with quite as much excess fuel as at lower speeds. With a leaner mixture the power holds up equally well at all speeds.

The above curves offer the explanation as to why of two cars of the same make, and of equally good mechanical characteristics, one can travel 10 miles on a gallon of gasoline and the other 15 miles. This is because on one car the carburetor gets a powerful but lean and therefore efficient mixture; while the other carburetor receives too rich a mixture.

The following rule is suggested for adjusting a carburetor: Decrease the quantity of gasoline until the engine loses power; and then increase it slowly until good power is restored, but not a notch beyond this point. (*S. A. E. Bulletin*, vol. 11, no. 5, February 1917, pp. 556-564, 5 figs. *ep*)

Machine Parts

Notes on Screw Gages, Col. R. E. B. Crompton

Paper presented to the Institution of Automobile Engineers. It begins with definitions of various terms used in discussion of screw gages as adopted by the Engineering Standards Committee (Great Britain), and then, after a brief history, proceeds to the discussion of the various threads, such as the Whitworth and British Association (B. A.).

The writer points out that notwithstanding the work done at Woolwich, at the National Physical Laboratory, and elsewhere, when the war broke out there was no satisfactory system in use for gage making. If gages had at that time been so designed that they could have been cheaply and readily produced in quantity, England would have saved many thousands of pounds and much delay in the turning out of shells.

One of the opinions as to the causes of difficulty in producing gages in England was that the rounded roots and crests of the Whitworth form of thread require elaborate plants and form a costly item in gage work. The American Sellers form and the Continental International thread use an angle of 60 deg. with flats on crests and roots, for which gages are more easily made.

The writer states further that when the demand for interchangeable screw work for shells became so pressing that a large supply of accurately made gages became necessary, it was found that many of the gages proposed in Report 38 of the Engineering Standards Committee were very difficult to make, especially those parts where accurate machining or lapping of the grooved portions of the thread at crests and roots were supposed to be necessary and were insisted upon in many of the government specifications. Of all the gages the most difficult to make accurately are the full-form "go" gages. As regards the theory and practice of these gages, it is evident in the first place that in order to secure interchangeability and at the same time take the fullest advantage of any tolerances which can be allowed on the work, the "go" plug-and-ring screw gages should each follow the same mathematical outline which is most naturally defined by the theoretical nominal size and form of thread. The tolerances on the work should be such that all screwed plugs are on or below this size and all screwed holes on or above it. In practice, however, it is not possible to make either gages or work so perfectly that the plug and ring of the *same* mathematical size will screw together. Some tolerance needs to be allowed on the gages themselves, and reference and check gages have also to be considered.

As regards tolerances on screwed work, the writer believes that part of a tolerance is a fixed quantity, i.e., that made necessary by roughness of surfaces, films of dirt, or similar physical matters, and this applies equally to a small screw and to a large one. It follows that the proportion which this constant tolerance bears to the thread depth in the small screw is very large as compared with the same constant tolerance applied to the large screw. This was not at first realized, so that it was found in practice that although the tolerances for the large screws laid down in Report 38 are workable, those for small screws on the Whitworth or B. S. F. scale (½ in. to ¼ in.) and the B. A. series were far too fine and are practically non-workable.

Hence the writer suggests that the whole series of screws, from 3 in. down to the tiny screws used for instruments, should follow one law for tolerances modified only by considerations of the method of manufacture. Small tolerances or close fit on effective diameter are chiefly required to prevent the screws and nuts from working loose.

As regards clearances, although decisions on this point are urgently needed, nothing definite has been done.

It is further evident in the opinion of the writer that if high-crested taps having a core diameter somewhat above the nominal are used for all nuts, the high crests will insure triangular clearances at the crests of the male threads and the increased core diameter of the tap will reamer away the inner salients of the nuts so that the threaded surfaces of bolts and nut will come in contact only on the slopes. Their fit, therefore, is a question of the tolerances on effective diameter. The full diameter and core diameter of the bolts may take care of themselves and, if specified at all, very wide tolerances might be allowed on them.

But if we allow the above clearances before addressing ourselves to securing a good fit by tolerances graduated according to the requirements of the work on effective diameter, we can greatly simplify the gaging question by practically confining it to the gaging of the male screws by means of an

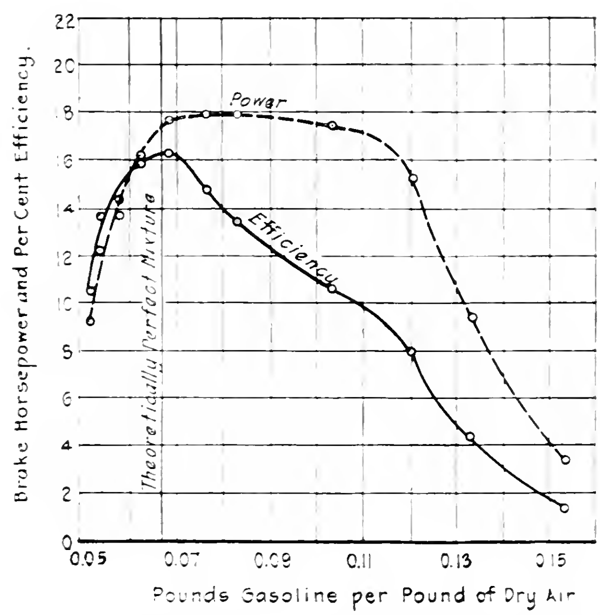

Fig. 7 Engine Performance Curves (1300 R.P.M.)

adjustable split nut accurately made as to pitch and thread form and cleared in such a manner that it only bears on the slopes of the threads that are to be tested and, therefore, tests the effective diameter only. Such a method of testing is not new but has rather been lost sight of.

As regards the gaging of nuts, the writer believes that the real gage for nuts is the tap, and nothing may improve screw interchangeability so much as improvement in tap manufacture. Errors in pitch introduced in the process of hardening taps must be minimized and a system of cutting the taps directly and accurately out of hardened blanks should be encouraged. (Paper presented before the Institution of Automobile Engineers, abstracted through the *Automobile Engineer*, vol. 7, no. 99, February 1917, pp. 35-37, *gp*)

Munitions

Heat Treating Shrapnel Forgings

Description of the methods used at the Hofman plant of the Symington Machine Corporation, at Rochester, N. Y.,

wh[illegible] Russian shrapnel are being made at the rate of over 10,000 per day.

The equipment for hardening the shell forgings consists of three twin chamber, double end, overfired oil furnaces built by the Metals Production Equipment Co., of New York. The combustion chamber of each of these furnaces is above the working chamber and is separated from it by a perforated arch of refractory tile. The oil is delivered from overhead feed lines to five burners at each side of a two-unit battery of furnaces. The oil is atomized by steam and delivered to the burners at 80 lb. pressure. The flame of combustion is retained in the combustion chamber and the heated gases flow down through the checked refractory arch into the working chamber containing the shell forgings. After circulating in this chamber the gases pass out through an outlet in the side wall into a duct under the chamber and up through flues in the other side wall to vents in the top.

The roughly machined forgings are placed in metal trays providing convenient means of quickly placing four shells at the proper distance apart so that the heat of the furnace may circulate between them.

Hydraulically operated cylinders push three trays of shells into the furnace when water under 70 lb. pressure is admitted to the cylinders.

After the furnace has been filled with trays of forgings each succeeding group of three trays that is pushed in through the door at the front pushes all the others before it so that the last one emerges from the door at the back. As the shells leave the furnace an operator inserts the hooks of a two-pronged rake into holes in each tray and by a quick movement pulls it forward on smooth ways to a stop.

The forgings are subjected to a temperature of about 1500 deg. fahr. for a period of one hour and twenty minutes. The following device is used for regulating the movement of the shells through the furnace. It was determined that in order to subject each group of forgings to the heat of the furnace for exactly the required length of time, three trays must enter the furnace every five minutes. To insure the strict observation of this schedule an electric gong was installed to warn the operator when it was time to place another group of trays in the furnace. The ringing of the gong is timed by a revolving drum driven by a small direct-current motor.

From the furnace the shells go into the quenching oil. The oil reservoir contains 8000 gal. of oil which is maintained at the uniform temperature of 120 deg. fahr. by an extensive circulating and refrigerating system.

All the furnaces are equipped with automatic recording pyrometers which are arranged on shelves in a room adjoining the superintendent's office.

An important feature of shell making is the formation of the conical-shaped nose of the open end of the shrapnel forging, and the mechanical method of pressing the open end of the forging owes its success to the physical properties imparted to the metal in the annealing process.

The article describes the general features of the annealing furnaces.

Among other things the writer calls attention to the fact that the previous work done to satisfy the exacting demands of automobile, locomotive, and machine-tool construction has brought the art of heat treating previous to the beginning of the present war to the stage which alone made possible the wonderful strides made in the new art of shell making in this country during the last two years. (*The Iron Trade Review*, vol. 60, no. 6, February 8, 1917, pp. 365-368, 6 figs. *d*)

Railway Engineering

Water Conditions in the Locomotive Boiler, George L. Fowler

Data of a recent study of boiler feedwaters on a railroad where there was a variety of troubles from this source. An important feature brought out by the investigation is the impossibility of depending on the analysis of the raw water as drawn from wayside tanks.

As regards the formation of scale, cases have been observed where the scale formed was of medium hardness and brittleness, and was easily removed from the surface to which it adhered by tapping it with the hand. Where the sheets were bare or the scale thin, there was no corrosion; but where the scale formed, corrosion took place beneath it forming a large pit as shown in Fig 8. The thicker the scale the deeper was the pit (Fig. 8).

As the water appeared harmless and the corrosion occurred only beneath the scale, it was surmised that the scale might be corrosive. A sample of it was analyzed (complete data given in original article), but nothing was found of a corrosive nature, and it would seem therefore that after the deposition of a certain amount of scale the plates beneath it became locally overheated. This caused a decomposition of the organic matter, the calcium sulphate and magnesium hydroxide forming free sulphuric acid, which is partially protected from dilution with the boiler water and attacked the sheets. The cure then lies in preventing an accumulation and adhesion of scale.

In another case there was little or no trouble from scale, but there was an intense and rapid corrosion that would destroy tubes by pitting in nine or ten months. The water that was doing this did not even give an acid reaction, and there was apparently nothing to account for the intensity of the action which actually took place. A lime-and-soda treating plant had been erected at one place, but the result appeared unsatisfactory.

After a rather thorough examination of analyses of the water, it was decided that something was happening in the boilers of which nothing was known. Two boilers were selected, the water of each of which had been taken from a single tank, and samples analyzed after having been in service for about eight days. The variation in the composition was startling, as shown by Table 1.

The water taken from the boiler was extremely bad. The free sulphuric acid coupled with a large quantity of organic matter fully explained the rapid corrosion that takes place in the boiler using the raw water from which it is formed.

Because of the uncertainty as to the uniformity of the quality of the water delivered to the boiler, an experimental small boiler, of about two gallons' capacity, was built, in which definite samples of water were evaporated. The boiler was operated under a pressure of 200 lb. per sq. in. The method of operation was to draw a quantity of water from the tank to be examined and analyzed; then to take 75 gal. of the sample and evaporate it to 1 gal. in the small boiler. Table 2 gives a typical result which presents a good example of the change repeatedly found to take place in water that has been subjected to the high pressure and temperature obtaining in a locomotive boiler.

While some compounds disappeared, others were apparently formed. In this case the raw water contained neither calcium sulphate nor magnesium chloride, and yet both were found in the water taken from the boiler. On the other hand, the sodium sulphate and magnesium carbonate disappeared. The

decomposition of the magnesium chloride formed hydrochloric acid, which directly attacked the sheets.

As to the decomposition of sodium sulphate, which may appear incredible, the writer states that in seven cases where these evaporation tests were made, each showed an apparent disappearance of the salt and the formation of new compounds that did not exist in the raw water.

In fact, an attempt was made to regulate this phenomenon. One of the worst of the waters was selected and subjected to the boiling test, followed by an examination. The raw water was then treated with sufficient barium hydroxide to precipitate all of the sulphates as barium sulphate. Again, a concentration test was made of 75 gal. of water thus treated, with the results given in Table 3.

These results show that notwithstanding the practical elimination of the sulphates and presence of a certain amount of organic matter, all of the sodium was retained in solution and combined with a liberated carbonic acid. Some of the

sulphuric acid and silicic acid were present, making the water strongly foaming.

For waters that did not lend themselves to successful tank treatment two methods were adopted to prevent the corrosive action, both of which appear to be working successfully. One is to make an examination of the water in the boiler each day and prescribe the amount of soda compound that is to be used. The examination requires only five to ten minutes' time and the application is made through a hose attached to the suction chamber of the injector. Enough of the compound is used to maintain the alkalinity of the water in the boiler at 0.3 per cent, which, while not entirely noncorrosive, is so nearly so as to avoid trouble.

The other and simpler method is to apply a corrosion inhibitive at each washout. If the boiler has been in service for some time and the corrosion has started, it has been found to require three or four applications to stop it. After that the water drawn from the boiler will be clear and free from oxides. Where this treatment is used and the water in addition to its corrosive qualities carries scale-forming matter in any quantity, it is necessary to add a scale preventive to the inhibitive. (*Railway Age Gazette*, vol. 62, no. 9, March 2, 1917, pp. 359-362, 1 fig. *cp*)

SOUTHERN RAILWAY DUPLEX LOCOMOTIVES

Description of the application of Mogul running gear and machinery to a Mikado locomotive.

By such an application the Southern Railway has materially increased the capacity of these locomotives without increasing the wheel load, and with a marked decrease in fuel consumption per ton-mile. This has been done with but little change to either the running gear of the retired engines or to the water tanks of the Mikados. The diameter of the cylinders of the tender engine has been reduced, which with the reduction of one inch in diameter of the Mikado-type cylinders, does not overtax the Mikado boiler to any extent. In addition to the reduction in cylinder diameter, the boiler capacity has been increased by the addition of brick arches

and a feedwater heater which uses the exhaust steam from the air compressor.

Steam for the tender engine is taken directly from the superheater, through a well-lagged 3-in. pipe extending backward underneath the cap. A second pipe which permits the added use of saturated steam taken direct from the top of the boiler, is also connected with this pipe. This has been added in order to provide greater steam supply to the tender engine for peak loads on heavy grades.

With the application of the Consolidation running gear to the tender, the drawbar pull of the Duplex locomotives is made 39 per cent better than that of the original Mikados.

Several of these locomotives have been installed on the line between Asheville, N. C., and Hayne, S. C., a distance of 68 miles. On this line, eastbound, heavy-traffic direction, there are 1.5 and 1.7 per cent grades.

With the single Mikado locomotives the maximum tonnage handled over the first 22 miles of this line is 1100 tons. The Duplex locomotive will handle 1400 tons, or an increase of 27 per cent.

As regards the factor of adhesion in the Mogul, with the minimum weight of tender, it is much too low, viz., 2.25.

with the tender practically empty of water and coal. In the case of the Consolidation tender, the minimum factor of adhesion is about 3.25.

Fig. 9 shows the application of the Mogul running gear and machinery to the water tank of the Mikado type locomotive. The entire lower part of the locomotive remains practically unchanged, the cylinder casting is retained intact, and the front and rear draft castings are changed slightly, the front draft casting being shown in one of the illustrations. A pocket is formed in the tank at the front end to provide a proper clearance for the rear cylinders. (*Railway Mechanical Engineer*, vol. 91, no. 3, March 1917, pp. 121-123, 6 figs. *d*)

Superheat in Locomotives

At the Fifty Ninth Annual Convention of the American Railway Master Mechanics' Association held in June 1916 at Atlantic City, N. J., a report was presented by the committee on superheated locomotives. W. J. Tollerton of the C. R. I. & P. Ry., Chicago, Ill., Chairman.

This report provoked an interesting discussion.

D. R. MacBain (N. Y. Cent. R. R.) spoke of tests with locomotives equipped with Schmidt superheaters. An engine was taken of exactly the same type as those used without superheaters and an accurate account kept of every gallon of water and every pound of coal used, and also of every car that was moved about the station—as closely as was possible. An actual saving of fuel on superheated locomotives was found. No claim is made that any high degree of superheat was obtained on a switching locomotive, but this is what was found: On three different tests it was ascertained that even in the summer time, say for the month of September, there was a drop of approximately 25 per cent in the steam temperature from the time it left the boiler until it entered the cylinder. This was the result of the saturated tests. With the superheated switching locomotive this 25 per cent was taken up; or, in other words, it became possible to maintain on that slow-moving, short-work switching engine just about boiler temperature in the cylinder. The experience of that road so far indicated is that on short switching not much superheat is obtained, but that a vast saving is secured, due to cutting out the condensation, especially on a switching engine working with practically cold cylinders.

C. F. Giles (L. & N. R. R.) discussed the use of the drifting valve. It was found very difficult to get the engineers to use a cracked throttle in drifting down a long grade. An intercepting valve in the throttle was introduced with the expectation that it would be kept open when the main throttle was closed. This did not prove entirely satisfactory and, besides, the steam that is taken into the cylinder from the superheater units is naturally superheated and one cannot get as good results from superheated steam in drifting as with saturated steam.

In October 1915 an automatic drifting valve was applied with satisfactory results. In this case the pressure from the valve chamber keeps the valve closed when the engine is working steam. There is a spring on the opposite side that allows the valve to open when the pressure from the valve chamber is cut off. The valve is connected by a pipe direct to the dome which provides saturated steam continuously to the cylinders while drifting, with a branch pipe running from each side of this drifting valve to the valve chamber.

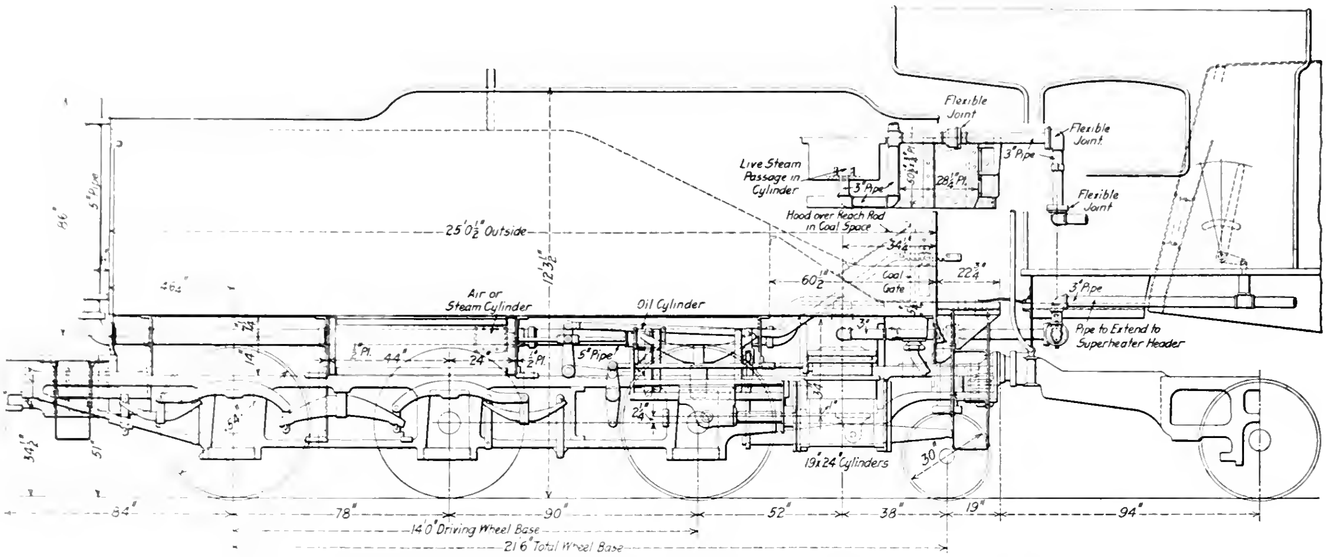

FIG. 9 APPLICATION OF MOGUL RUNNING GEAR AND MACHINERY TO WATER TANK OF MIKADO LOCOMOTIVE

The speaker had the valve chamber and cylinders on the first engine to which the valve has been applied opened up and found that they were lubricated as satisfactorily as any saturated engine he has examined.

H. C. Woodbridge (Assistant to Gen. Mgr., B. R. & P. Ry.) discussed the operation of slide-valve locomotives with high-degree superheat. About three years ago he tried a method by which the face of the valve and seat were bathed with lubricated saturated steam, and a circulation between the seat and the valve face established. He ran the engine using saturated steam for eleven months, testing it out as far as possible with a wide-open throttle and a short cut-off for long distances. A Schmidt superheater was then applied to that locomotive. Since the application the engine has made 35,000 miles, being handled during the past five or six months in pooled service, and in that pooled service the engine was allowed only 1¾ pt. oil for a 107-mile run. (The writer believes that this oil allowance should be increased to properly provide for irregular service.) The locomotive, a 40,000-lb.-tractive-effort consolidation engine, was then put in passenger service to see if the valves could be burned out. It performed

very satisfactorily on the fastest trains where it was necessary to run 53 to 54 miles per hour, which, with a small wheel, means 5 r.p.s. a good deal of the time. The same scheme was applied to an Atlantic-type passenger locomotive carrying 200 lb. of steam and is at present being applied on a Decapod pusher engine.

The writer expressed his belief that the distortion of a properly designed slide valve will not be sufficient to cause any trouble if it is properly lubricated. After the writer had found a slight distortion in the valves run with a superheater he was surprised to find just as much distortion in the same character of a valve with saturated steam.

R. P. Blake, speaking of his experience on the Northern Pacific, stated that observations of the performance of the engines led to the conclusion that there was little if any advantage in the five-feed lubricator. The same quantity of valve oil regularly and properly introduced into the cylinder through the valve would give better results than attempting to feed part of it into the cylinder direct. At present the results which are being secured in cylinder packing are probably averaging about 20,000 miles between renewals. (*Report of the Proceedings of the 59th Annual Convention of the American Railway Master Mechanics' Association*, Chicago, 1916, vol. 49, pp. 130-155, *g*)

Sieves

A Standard Screen Scale for Testing Sieves

Since the adoption by the Bureau of Standards several years ago of specifications for standard 100- and 200-mesh sieves, frequent requests have been received that this Bureau test and certify sieves of other sizes than these. With a view to the adoption of a series of standard testing sieves which might be of use to all industries making fineness tests, this Bureau for two years has been studying the question of such a standard screen scale. Various scales that have been proposed were considered, and information was sought of representative firms in the various industries interested as to their requirements. Manufacturers of sieves have also been consulted as to the desirability of different screen scales and the practicability of their manufacture. As a result of this study of the question, a conference was called at the Bureau of Standards April 20, 1916, of representatives of various committees of the American Society for Testing Materials. American Society of Civil Engineers, American Institute of Mining Engineers, American Foundrymen's Association, Mining and Metallurgical Society of America, American Water Works Association, American Institute of Metals, and the American Spice Trade Association; also representatives of the Committee of Revision of the U. S. Pharmacopœia, the U. S. Geological Survey, the U. S. Bureau of Mines, the U. S. Office of Public Roads and Rural Engineering, the U. S. Office of Grain Standardization, and the U. S. Bureau of Standards; also representatives of a number of private firms engaged in industries in which sieves are used, such as the glass, the drug-milling, the abrasive, the asphalt, the mining, the spice, the chemical, and the graphite industries; also representatives of the firms in this country manufacturing wire cloth and sieves.

This conference, after considering the various screen scales either proposed or now in use, adopted as a Standard Screen Scale that given in a table in the original paper, and recommends that it be adopted generally by scientific, technical, and engineering societies and committees, and by branches of national, state, and municipal governments as a part of their specifications for materials and methods of tests; also that it be used by private firms who have need of standard sieves.

This screen scale is essentially metric. The sieve having an opening of 1 mm. is the basic one, and the sieves above and below this in the series are related to it by using in general the square root of 2 (or 1.4142), or the fourth root of 2 (or 1.1892), as the ratio of the width of one opening to the next smaller opening. The first ratio is used for openings between 1 mm. and 8 mm., while the fourth root of 2 is used as the ratio for openings below 1 mm. to give more sieves in that part of the scale. The series has been made large enough, it is hoped, to meet the needs of all industries. Some industries may have occasion to use all the sieves in a certain section of the series and none of the others, while in other industries it may be desirable to use only certain sieves selected from the whole range of the series. In making such selections it is recommended that this be done on some systematic plan, as, for example, the selection of every other sieve or of every fourth one in the series below 1-mm. opening and every other sieve above 1-mm., in which case the ratio of each opening to the next smaller one would be as two to one.

Because of the wide range of openings in sieves now manufactured which are possible with a given number of meshes of wire per unit length by the use of wires of different diameters, and the consequent confusion and uncertainty which arises in designating sieves by the number of meshes per unit length, the sieves of this series have been designated by the width of the opening in millimeters, as, for example, a 1.41-mm. sieve, or a 0.36-mm. sieve. It is urgently recommended that all users of sieves in the future designate these standard sieves in this way and that the manufacturers mark and list the sieves in this manner rather than by the meshes per inch.

In the designation and certification of the sieves the metric units will be used by the Bureau of Standards. In the table (in the original paper), however, are also given the equivalents of these metric quantities in inches in order that the series may be more readily related to work previously done. It is, of course, immaterial whether units of the metric system, or of the customary system, or of any other system are used in the manufacture of the sieves provided they are within the tolerances.

To meet the need for sieves of this series at the present time a temporary provision has been made in the specifications for the acceptance of sieves of slightly different mesh and wire diameter than those called for in the screen scale, provided the resultant opening is the same as the nominal opening within a small range. This will make possible the use of a number of sieves now on the market in which the ratio of wire diameter to opening is only slightly different from that of the screen scale. This provision will be withdrawn when conditions are such that the manufacturers of sieves can furnish sieves made more exactly in accordance with the specifications.

The Bureau of Standards hereby announces that it will test sieves of this series to determine whether they conform to specifications given below. This test will consists of the examination of the mesh of both the warp and shoot wires of the cloth to ascertain whether it comes within the tolerances allowed; also measurements of the diameter of wires in each direction to determine the average diameter, and a measurement of any large openings to ascertain whether they exceed the limits given in these specifications; also an examination of the sieve to discover any imperfections of the sieve which

may seriously affect its sieving value. Sieves which pass the specifications will be stamped with the seal of this Bureau and will be given an identification number, and a certificate will be furnished for each sieve that passes the requirements.

For sieves which fail to meet the specifications, reports will be rendered showing wherein the sieve was not up to the standard.

A fee of \$2.00 per sieve will be charged for the test of the sieves when submitted singly. For from two to nine sieves submitted at one time the fee will be \$1.50 per sieve. For lots of ten or more the fee will be \$1.00 per sieve. Only half of the above fees will be charged for such sieves as may be rejected for exceeding the tolerances of mesh, in which case the wire diameter will not be measured. (*Abstract from an advance notice supplied by the Bureau of Standards,* Washington, D. C.)

Steam Engineering

Ford Boiler and Gas Plants, Thomas Wilson

In the Ford boiler plant seven of the largest boilers yet to be put in operation are in the course of erection. They are of the Badenhausen six-drum type, with six passes over the gases and with 25,000 sq. ft. of heating surface. While rated at 2500 hp., it is proposed to operate them continuously at 4000 hp. Steam will be generated at 180 lb. pressure and superheated to a temperature of 600 deg. fahr.

The article describes in detail the system of location of the boilers, which permits of an important economy of space.

Each boiler will be served by a 12-retort Taylor stoker of especially large size, driven by a variable-speed motor through a silent-chain drive. Clinker crushers are provided with a 5-hp. constant-speed motor at either side, with the drive by belt, gear box and ratchet, the throw of the latter being adjustable.

The water-back is of special design. It consists of two headers in the open space at the rear of the bridge wall, with $3\frac{1}{4}$-in. U-shaped tubes placed $6\frac{3}{4}$ in. apart passing through the bridge wall and projecting far enough to prevent clinkers coming in contact with the brickwork. Expansion is taken care of by arranging the brickwork to give a space of $\frac{1}{2}$ in. around the tubes, which space is packed with asbestos. By drawing them into the furnace the tubes can be removed without seriously interfering with the bridge wall. The headers are flexibly connected to the boiler by long bends and provided with handholes through which the tubes may be expanded or cleaned.

As the feedwater enters at the rear, the coldest water in the boiler goes to the water-back. The flow enters into and assists the regular circulation of the boiler. There are four blow-off connections to each boiler: two on the lower drum of the economizer section, and two on the lower drum of the boiler proper.

To obtain the high superheat anticipated, a Superno superheater is located between the first and second passes, or in the path of the gases just after the first bank of tubes. To obtain uniform heat transfer, a superheater is made up with an increasing number of tubes of decreasing diameter, the constant area approximately equal to the steam-outlet area from the boiler.

Between the third and sixth passes is located a damper hinged on to the boiler side and closing against an angle iron on the division wall between the two lower drums. Normally, this damper will be closed, and all of the gases will flow through the six passes of the boiler. Should the draft be lower than usual and it is desired to reduce the drop through the boiler, the damper will be raised so that a portion of the gases will enter directly from the third into the sixth pass.

When the plant is complete, the intention is to induce the draft by utilizing the exhaust from the gas engines. It is expected that the temperatures of both exhaust and stack gases will approximate 300 deg. fahr., so that the exhaust will be called upon to increase the draft.

In the small Wickes boilers, also, the steam is generated at 180 lb. pressure and superheated to 600 deg., with the boiler feedwater raised to a high temperature in the gas-engine cylinder jackets and the feedwater heaters.

The heat in the stack gases is utilized in an air preheater rather than in an economizer. The preheater consists of a rectangular sheet-iron box with tube sheets and 190 tubes of $3\frac{1}{2}$ in. outside diameter, placed on 6-in. centers both ways, set in the uptake from the boiler. The gases pass through the tubes. The air from the fan comes in at the side of the preheater, flowing across the tubes and back to the outlet, thence down through a duct to the wind box of the stoker. A series of sleeves with baffle flanges fit over the tubes to increase the area of contact, and to stratify the air so that all the surface will be used to advantage.

In the water heaters each unit is divided into four elements, receiving the exhaust and the jacket water from three engines. The gases pass through the four elements in series counter-current to the flow water. It is estimated that they will enter at the temperature of 550 deg. fahr. and leave at possibly 300 deg. The water leaves the gas-engine jackets at an average temperature of 195 deg., and it may reach a temperature of 275 deg. in the heater before being delivered to the economizer sections of the boilers.

The article describes in detail the ash- and coal-handling equipment and the gas-producer plant. In connection with the latter, it is stated that recently an experimental producer was built to make gas which would not require scrubbing apparatus. The outfit consists of a standard Hughes producer, fed with coal and discharging gas to another producer of special construction charged with coke, the tarry vapors in the gas from the first producer being fixed into permanent gases by passing through the bed of hot coke in the second machine. This unit is now in operation. (*Power,* vol. 45, no. 8, February 20, 1917, pp. 239-243, 5 figs. *d*)

Large Modern Steam Power Plant

Description of a large power plant of the Buffalo General Electric Company, the interest of which lies in its use of a pressure of 275 lb. and a superheat of 275 deg., together with a general discussion on the future of high steam pressures.

A consideration of the general state of the art of steam-power generation tends to indicate that except for the gain of 10 or 12 per cent that might be added by increasing the heat range by going to higher pressures or higher superheat, there appears to be at present no other source for bettering the economy of the steam plant.

The passage from the high pressures of today, 180 to 225 lb., to such as 600 lb., is not likely to come in a single jump, as it requires suitable materials of construction and a change in the whole steam side of the station. Further, because with pressures like 600 lb. the dew point is advanced much nearer to the comparatively inefficient high-pressure

stages of the turbine, there appeared to be serious obstacles in the way of an immediate increase to 600 lb., or thereabouts. It is, however, likely that in the near future, large turbines will be ordered so designed that a high-pressure wheel may be put on if it is desired to increase considerably the boiler pressure after installation, as has already been done at Boston.

The writer discusses in this connection the various features of high-pressure and high-superheat turbines, such as turbine materials and wheel friction. As to this latter the writer calls attention to the experiments of Konrad Anderssen, who found that the resistance to rotation in the wheel is approximately proportional to the density of the steam, and that it increases with the fifth power of the diameter of the wheel and the third power of the revolutions.

From this the writer passes to the description of the Buffalo plant. While much of the power required for the industries at Niagara Falls, and for some at Buffalo, has heretofore been exported from the Canadian side of the Niagara River, the Canadian authorities have curtailed the sale of this power to American industries, and for this reason to the other head. One connection from each header joins a receiver at each turbine, with which 15 in. diameter bends connect the turbine. The figure shows how well provided is the piping for the movement that 275 lb. pressure and 275 deg. fahr. superheat make inevitable.

All valves on the main steam piping except throttle valves are gate valves. The valves in the high-pressure steam lines are all steel. Although the steam velocities are not unusually high, the valves have been provided with seats designed to minimize the cutting and scoring effects of wire-drawing. The article illustrates various types of valves used, such as the boiler drumhead stop and check valves having the disk for seat screwed in instead of formed or pressed in, and seats, disks and stems of monel metal.

As regards boilers, the rate of coal feed by the plungers with the boilers operating at normal rating is 127 lb. per retort per hour. The stoker is capable of being operated to feed 1000 lb. of coal per retort per hour. When feeding 700 lb. per retort per hour, or 10.5 tons per boiler per hour, the boiler will evaporate about 160,300 lb. water per hour, from and at 212 deg. fahr., or 14.4 lb. per hour per sq. ft.

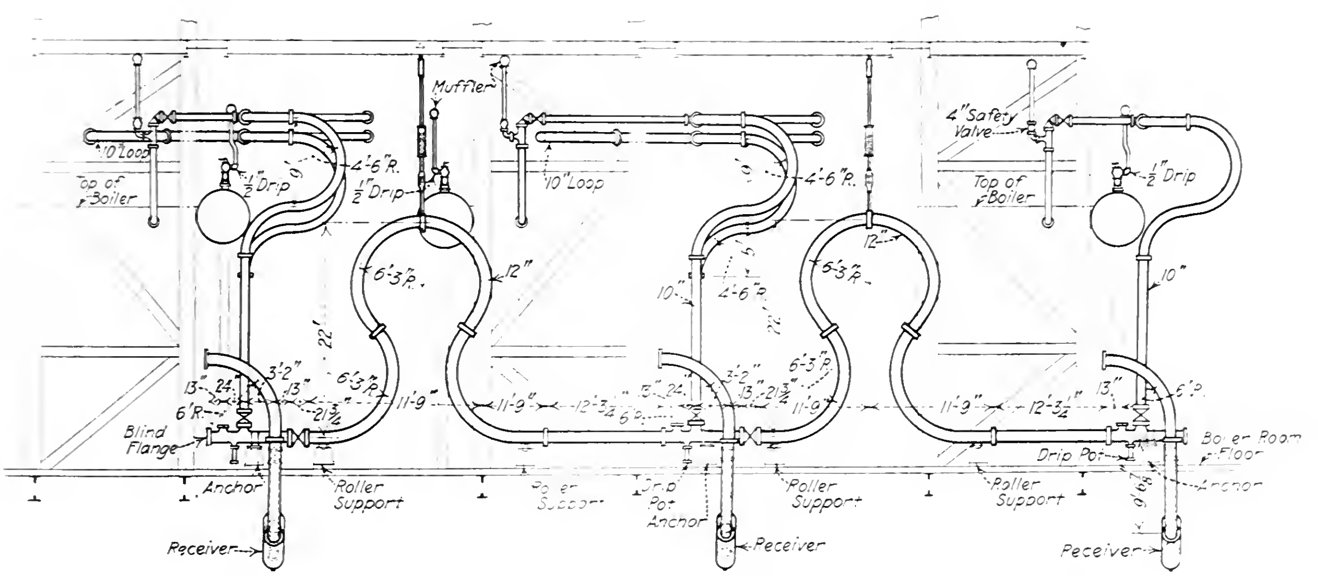

Fig. 10 Elevation of Steam Main and Leads from Three Boilers, Buffalo General Electric Company

the River Station of the Buffalo Electric Co. was built on Black Rock just outside the city limits of Buffalo, N. Y. The station was planned for 200,000 kw. capacity, 3 units each of 20,000 kw. at 90 per cent. power factor being installed initially; future units are to be 30,000 or 35,000 kw.

As regards time of construction a world's record has likely been made. The ground was broken for this work in January, 1916, and the station was put in commercial operation in November of the same year, a truly remarkable performance even in normal times, and especially when one realizes that the conditions of steam temperature and pressure require a considerable amount of special material.

An interesting feature is the high-pressure steam piping. As one stands facing the boiler-room wall, the bends in the 12-in. steam mains rise 23 ft. above the floor, as high as the boilers. Each bend, as shown in Fig. 10, consists of three parts, two 45-deg. bends from the horizontal, joined by a U-bend of 6ft. 3 in. radius, producing a double offset bend with four joints. There are two 12-in. headers, the 10-in. leads from the boilers at one side of the house going to one of these; the leads from the boilers on the other side going of heating surface. Hence, overload capacities can be obtained which would have been deemed impossible a few years ago. In fact, these boilers are heavily over-stokered as compared with usual practice.

The raw-water evaporator system for supplying distilled make-up feedwater is of interest. The purpose of it is to prevent formation of scale in the boilers or elsewhere in the system. This make-up water evaporator system has a capacity of 30,000 lb. of distilled water per hour, 24 hours per day. Distillate to have less than five grains of solid matter per U. S. gallon upon evaporation to dryness.

The diagrammatic layout of the evaporator plant is shown in Fig. 11. In the evaporator proper, the coils are of 1-in. outside-diameter seamless drawn-brass tubing wound in small coils so as to be quickly detachable. It is in the evaporator that most of the scale is formed and from which the sludge is blown to the waste pipe. The steam pressure is 275 lb. from the boilers, and the superheat 275 deg. As the heat transmission from superheated gas such as this steam is not as great as when saturated steam is used, a reducing valve and a de-superheater are used to reduce the steam to saturation at

[illegible] before it goes to the evaporator. One should, to facilitate the understanding of the system of Fig. 11, begin by tracing the lines from the raw water line, or start at the hot well and trace the course of the condensate from the hot well of the turbine condensers through the evaporator system condenser, and to the main open feedwater heaters, from which it goes to the economizer and then to the boiler. The raw water which is taken from the circulating water discharged from the main condensers, enters an open heater supplied with steam from the exhaust of the auxiliaries and then passes through a heated generator, the shell of which is supplied with vapor from the second effect evaporator, while the raw water passes through the opening of each evaporator.

The evaporator system is practically automatic in its operation, and the evaporators may follow very closely without personal attention the output as required by the load on the plant, or in accordance with the feedwater requirements.

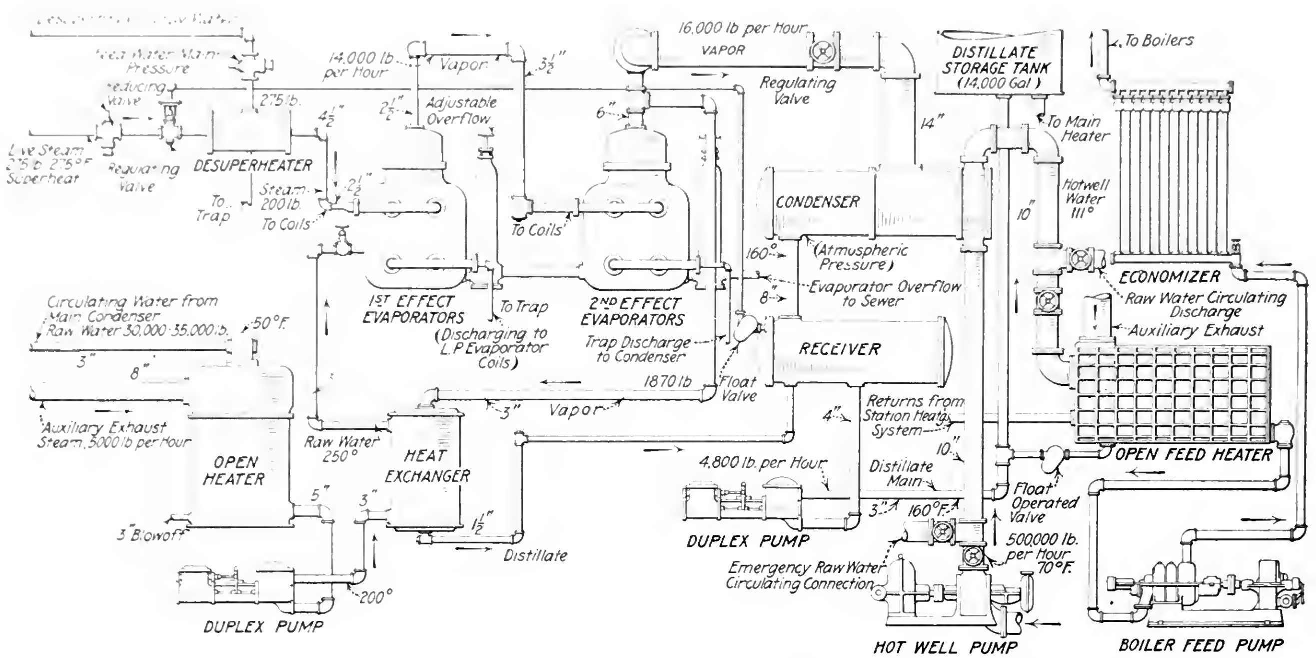

FIG. 11 DIAGRAMMATIC LAYOUT OF MAKE-UP WATER EVAPORATOR SYSTEM HANDLING 30,000 LB. DISTILLATE PER HOUR, BUFFALO GENERAL ELECTRIC COMPANY

Varia

SCIENTIFIC PROBLEMS AWAITING SOLUTION

Henry le Chatelier, in a recent address to the French Academy of Sciences, indicated certain scientific problems with special reference to French engineering which still await solution.

The French industries are now actively interested in attempts to produce laboratory glass, which hitherto used to be imported from abroad. At present they are only melting experimental masses at a considerable cost in time and money. At the same time it is known that the main property of glass on which depends the entire success of production is the extension of the range of its fusibility. Preliminary measures of the variation of the viscosity of glass as a function of temperature and chemical composition would be of inestimable value, in that they would reduce the necessary number of experiments on a commercial scale, and while these latter experiments cost hundreds of francs each, laboratory experiments could be carried out in small platinum crucibles with a dozen grams of material, and would cost quite little.

The same methods could be used for the preparation of test pieces for the determination of expansion, which is of such great importance in ceramics, and for the determination of electrical resistance in insulators, and of chemical stability, valuable in chemical analysis.

Here, in the opinion of the speaker, lies a field of scientific work of the greatest value.

Metallurgy. Penetrating projectiles used in the navy must have a very hard tip in order to pierce surface-hardened armor plate. Hence, in order to control the production of these projectiles, it is necessary to have a method of measuring the hardness of heat-treated steel. As a matter of fact, we have not got it. The least unsatisfactory of all that we have at present is the Shore scleroscope, which uses the rebound of a small steel projectile having a diamond-pointed end. The results are, however, not comparable, since in addition to hardness they are affected by various elementary factors, especially the shape of the pieces tested.

The study of the behavior of elastic bodies under shock is a matter of great interest, but so far as this problem is concerned, knowledge has scarcely advanced beyond where it was left by Leonardo da Vinci. The rebound amounts, on the average, to three-quarters of the height of fall, varying from 60 to 90 per cent of this height. Calculus, together with experiments, would no doubt rapidly advance our knowledge and supply means for determining the conditions under which the rebound would depend only on the hardness of the surface of the body measured.

Pyrometry. The measurement of heat and temperatures acquires a constantly growing importance in the industries. Each one of our shops for heat-treating projectiles uses a good many pyrometers. Unfortunately, their indications are not as precise as would be desirable. One cannot use the standard

gas thermometer, which is too complicated for use outside of physical laboratories. The Siemens-Callendar platinum thermometer is very exact, but too fragile for everyday use in shops. The only three types of pyrometers exclusively used in shops are the thermo-electric, optical, and calorific radiation pyrometers. But their readings are not sufficiently exact.

Their defects are not due to the capricious action of natural laws. The laws are absolutely uniform in their action, but several elementary factors or several independent variables act simultaneously, and should we happen to neglect any of these factors, or even to fail to make sure that they remain absolutely invariable, we would obtain results necessarily lacking in precision, in accordance with the greater or lesser importance of the neglected factors.

The thermo-electric force of a couple depends, above all, on the temperature at the welded joint, but also, in a lesser degree, on the law of distribution of temperatures along the conductor between the hot weld and the cold weld. This is a phenomenon which we know qualitatively, but its quantitative investigation is still to be made.

The homogeneous wire heated in the middle under such conditions that the gradient of temperature differs from one part of the heated zone to the other, generates a parasitic thermo-electric force, and this phenomenon varies in intensity with the nature of the metal used.

The readings of the optical pyrometer depend on the emissivity of the bodies observed. Hitherto the emissivity of three bodies has been determined: platinum, oxide of iron, and oxide of nickel. A good many other common bodies are still to be studied.

The results obtained with a radiation pyrometer are affected by the variable distribution of temperatures in the metal box of the apparatus. This factor is yet to be studied, and it is also necessary to determine the conditions required to eliminate this disturbing cause.

Heating. The heat conductivity of materials used for walls of commercial furnaces, and also that of the masses of coal burned on the grates, are essential factors in the problem of proper utilization of combustibles. The conductivity of metals is known, but for refractory materials we have only empirical data which vary as much as 100 per cent in accordance with conditions of manufacture. There is no information at all, even empirical, as to the heat conductivity of the masses of coal; and still this conductivity is an essential factor in the important matter of the possibility of burning out the grate bars. To make these measurements really scientific, it would be necessary to carry out experiments on heaps of spherical balls of known constitution, systematically varied as to diameter and temperature. In this way it would be possible to determine the laws of transmission of heat through porous masses, of radiation, convection, and of conduction proper.

In the course of the same experiments one could determine the laws of flow of gases through masses of this character; and the results obtained would be used not only for heating but also for the selection of molding sands and in other problems.

The author discusses in a similar manner certain problems affecting agriculture. (*Quelques problèmes scientifiques à résoudre,* Henry Le Chatelier. *Le Génie Civil,* vol. 70, no. 6, February 10, 1917, pp. 95-96, *g*)

Detinning Apparatus

Prior to the war steel scrap in the form of cans, etc., was shipped from England to Germany for removing the tin, solder and zinc. The following apparatus has been recently patented in England to do the work at home.

The apparatus essentially consists of a slowly rotating inclined cylinder and a stationary hopper with a sleeve encircling the rotating cylinder. The latter has a feed aperture which once in every revolution registers with the aperture on the hopper and allows the cans to be fed into the internal heating chamber. To reduce the friction the latter is mounted upon roller bearings. The heating is effected by gas or oil burners.

The heating chamber is surrounded by a firebrick-lined cylinder with outlets for the products of combustion through the short flues at the top. Cans feed into the heating chamber, gravitate slowly through as the chamber rotates, and eventually find their way to the outlet where they pass down the chute. The temperature is gradually raised along the length of the chamber and is the highest at the outlet end. In the interior of the heated chamber channels are formed for collecting the molten tin and solder. *Aeronautics,* vol. 12, no. 170, January 17, 1917, p. 55, 1 fig., *d*)

American Institute of Mining Engineers

The 114th Meeting of the American Institute of Mining Engineers, which was held in New York City, Feb. 19 to 22, was one of public, technical and social interest. The general or public interest of the meeting was more than is usually the case, due to the activities of the Institute in connection with public affairs as well as to papers of general interest, as for example: a new source of potash supply (the isolation of Germany has cut off the chief source of this material); a study of the world's reserves of manganese ores and of petroleum; and finally a research on the subject of erosion of guns. This latter paper attracted the interest of members of the Naval Consulting Board, of experts of the United States Army and Navy and of the Spanish Military Commission, many of whom attended the meeting and discussed the paper. General interest also centered around the personality of Herbert C. Hoover, Chairman of the Commission for Relief in Belgium, who, since before the war, has been a Vice-President of the American Institute of Mining Engineers and who was guest of honor at the Reunion Smoker and at the Annual Dinner, where announcement was made that he had been elected an Honorary Member. Finally, ladies of the families of members of the Institute gathered to the number of about one hundred, and formed a Women's Auxiliary of the A.I.M.E., "for service along any lines which may prove useful now or in the future to the country or community or to humanity at large." The activities of the Auxiliary are being extended to every part of the globe where mining engineers and their families reside.

The technical interest of the meeting is indicated by the fact that eighty-five per cent of the papers presented were discussed. In some cases the discussion was more important, and in some cases more voluminous, than the paper which brought it forth.

The social features of the meeting included a Reunion Smoker, on Monday evening; the Annual Dinner, on Tuesday evening; an Exhibition of Moving Pictures in colors, on Wednesday evening; Luncheon for all members and guests, including the ladies, on each day; and finally, an All-Day Excursion to the West Point Military Academy, by special train, on Thursday, Washington's Birthday, where the members and guests were royally entertained by the Superintendent and his staff, and where they had the opportunity in

[illegible] entertaining [illegible] at luncheon. Other most enjoyable occasions in connection with the meeting consisted of a visit to the magnificent Art Galleries of Senator William A. Clark and Henry C. Frick, Esq., Tea and Exhibition Ice-Skating on the roof of the Waldorf Astoria, a theatre matinee for the ladies, and a visit to a moving picture studio.

Bradley Stoughton,
Secretary.

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquiries for further information in connection with articles reported in the Survey.

A new society under the name of the American Institute of Weights and Measures has been organized, with the purpose of opposing the introduction of the metric system in the United States.

The following officers were elected: President, W. R. Ingalls; Vice-Presidents, Henry D. Sharpe and D. H. Kelly; Treasurer, Walter M. McFarland; Secretary, F. A. Halsey.

According to a statement given to the press by State Engineer (New York State) Williams, daily service on the new Barge Canal between Buffalo and Albany will be begun in May. This will mean direct barge connection between the Great Lakes and the Port of New York, although facilities for the reception of all classes of freight will not be provided until next year. Freight rates will be approximately two-thirds of the railroad carrying charges.

In anticipation of the early need of cars of higher average capacity than those now in common use, the Pennsylvania Railroad, according to the *Railway Review*, has constructed a hopper gondola car of eighty-five tons capacity. This particular car has been constructed as an experiment, but if should prove successful, will serve as a model for future coal-carrying equipment. The design involves the use of four-wheel trucks and imposes loads thereon in excess of 60,000 lb. per axle, which approaches very nearly the limits recognized in locomotive construction.

When a modern large gun is fired with nitrocellulose smokeless powder, the temperature of combustion reaches from 4,000 to 5,000 deg. fahr.; and if the powder contains 25 per cent of nitroglycerine, it may rise to 5,000 to 6,500 deg. Steel melts at 2,650 deg. fahr., and a thin film of steel is fused in about one-sixtieth of a second. As soon as the projectile has left the gun, the big outflow of gas washes away a portion of this thin film of fused steel, and the bore is thus enlarged 0.001-in. in a 14- or 16-in. gun at each shot. With 58 per cent nitroglycerine, as in some English powders, the erosion is much greater.—Hudson Maxim, at the A.I.M.E. Annual Meeting, New York, Feb. 21, 1917.

The Pennsylvania Railroad has recently installed at Pitcairn, Pa., a novel type of plate-fulcrum track scales. This form of construction eliminates the knife edges which have been practically universally employed in scales of all kinds. In consequence of this change, the need of regrinding and renewing knife edges and bearings is done away with.

The place of the knife edge is taken by a thin plate continuous from lever to bearing. These novel plate fulcrums consist of relatively thin central portions connected to heavier portions or heads. The thin portion gives the desired flexibility, while the large heads distribute the load on the supported members and decrease the unit stresses. The design is such that the necessary vibration is taken care of without need of such wear as takes place in a knife-edge scale.

As a result of experiments recently carried out at the Consolidated Gold Fields Laboratory, an easy, cheap, and effective method of removing iron oxide from corroded and pitted iron plates has been evolved. Previous practice on the Rand has been to remove this mechanically, either with hammers, chisels, or a sand blast. While largely efficient, each of these methods is liable to leave traces or nodules of rust, especially at the bottom of the pitting, and these nodules prevent the covering of paint adhering to the iron and form nuclei for further corrosion.

The method evolved consists in applying to the surface of the iron a mixture of finely crushed sodium bisulphate and common salt, in the proportion of two parts of the former to one of the latter. This mixture is prepared, then wetted (just sufficiently to be cohesive) and applied to the iron plate. If time be no object, the moist mixture can be left until the plate is clean, but the action is much more rapid if the mixture is scraped off every two or three hours and the iron scrubbed thoroughly with a wire brush, applying water at the same time. The treatment is repeated until the plate is clean. Usually 24 hours is sufficient for a badly corroded plate.

The liberation of hydrochloric acid takes place slowly, and its action on the metallic iron appears to be slight.

When the plate is thoroughly clean it is washed well, finally with an alkaline solution, and dried quickly. A coating of paraffin oil is at once applied to protect the surface against atmospheric action. The metal is then ready for application of paint or other protective covering.

At the College of Engineering of the University of Minnesota a new educational experiment is being tried in the application of the task-and-bonus plan to the departments of shop work and design. Every job given to a student carries with it the time allowed, which is estimated on a fair basis. Any time saved by the student is given to him as a credit by means of which his time in college may be shortened if he accumulates a sufficient amount. It is assumed that the best men can save one-third of the time; and on the other hand if they prefer to do more work and not use the credit in reducing the time spent on the subject they can get one-third more value out of the course.

Prof. J. J. Flather reports that the system is working well both in the shop and drawing room and that all the instructors are enthusiastic in its application. The output per individual is at least 25 per cent and in some cases 50 or 60 per cent more than was the average before the scheme went into effect. There is an increased enthusiasm on the part of the men; their ambition is stimulated, and no drop in the quality of the work has been apparent. In fact, there is a strong tendency to maintain a high standard because additional credit is given for superior work and an extraordinarily good man may earn one-third bonus for quality in addition to the bonus he may earn for quantity.

Diagram for figuring dimensions of dished heads.

Wing Loading and Lift Coefficients. Flight, vol. 9, no. 5, February 1, 1917, pp. 105.

LIBRARY NOTES

From the Libraries of the Four Founder Societies and the United Engineering Society, in the Engineering Societies Building, New York City

Our New Librarian

W[illegible] the appointment of Dr. Harrison W. Craver, until recently librarian of the Carnegie Library of Pittsburgh, to be Director of the combined [illegible] of the American Society of Civil Engineers, the American Institute of Electrical Engineers, the American Institute of Mining Engineers, The American Society of Mechanical Engineers, and the United Engineering Society.

Dr. Craver was born in Owaneco, Illinois, August 30, 1875. He was educated in the public schools of Carmi, Illinois, and Terre Haute, Indiana, and the Rose Polytechnic Institute, from which he was graduated in 1895, having specialized in industrial chemistry. The following year was spent in post-graduate chemical study with Dr. W. A. Noyes. In 1896 he became chemist to Kirkpatrick & Co., Limited, of Pittsburgh, and later to the Shoenberger Steel Co., the Virginia Iron, Coal & Coke Co., and the Duquesne Reduction Co. During this period he acquired a practical knowledge of iron metallurgy, particularly of open-hearth steel manufacture.

Dr. Harrison W. Craver

In 1900 Dr. Craver first became associated with the Carnegie Library of Pittsburgh, being asked by the librarian, Dr. Edwin H. Anderson, now director of the New York Public Library, to undertake the organization of a technological department. To this work his attention was given until 1908, although interrupted by some returns to metallurgical work. Among these the most important was in 1902, when he became assistant superintendent of the Allegheny Steel Co., then in process of organization, and was placed in charge of their rolling mills. In 1908 he was elected librarian of the Carnegie Library of Pittsburgh, which position he has held since.

Dr. Craver's library experience has been unusually varied. The Technology Department, his first task, was a venture in a field hitherto untried, as no municipal library had attempted to meet the special wants of engineers and manufacturers. The methods of organization and the plan of service adopted have proved the model for the technology departments since inaugurated in most similar institutions in America. He has developed an unusual system of coöperation with the public schools and has been able, through the constant succession of bibliographic publications issued by the Library under his direction, to be of service to libraries and students throughout the world. The bibliographies on engineering subjects have been especially appreciated.

Among librarians his services to the profession have long been recognized. He has been since 1909 a member of the Council of the American Library Association, a member of the Executive Board since 1913, and Chairman of the Finance Committee since 1914. At present he is also First Vice-President of the Association.

Dr. Craver has been a member of the Engineers' Society of Western Pennsylvania since 1900. He was for several years a director of the society and chairman of the publication committee. He is also a member of the American Chemical Society and of the American Association for the Advancement of Science.

Now that the libraries of the four Founder Societies are grouped under one roof, an opportunity occurs to mold them into one all-embracing Engineering Library and to render this of service to the greatest degree to the members of the Societies and the profession generally.

Dr. Craver will be given most cordial support by the Library Board to develop his ideas and bring this all-important problem to a successful issue.

Library Service Bureau

THE Library Service Bureau, conducted by the United Engineering Society, has greatly increased its clientele since its foundation in April 1915. Service has been rendered to correspondents in 239 localities in 45 States in the United States, as is shown on the map here reproduced, and to foreign correspondents in 70 localities in 23 foreign countries. Photostat copies of articles in engineering periodicals have been sent to far-distant Australia, Korea and South Africa. Bibliographical assistance has been given in connection with the unification of railways in Australia, and the revision of the mining laws in that country; the development

of mining in China, Korea and South Africa; the raising of a sunken vessel in Chile; the construction of oil storage tanks in India, and the electrification of railways in Austria. The service is therefore nation-wide and world-wide.

American Iron & Steel Institute. Year Book. 1910, 1912-1915. *New York, 1910, 1912-15.* Gift of American Iron & Steel Institute.

American Library Annual, 1915-16. *New York, 1916.* Purchase.

American Railway Engineering Association. Proceedings, vols. 15-17. *Chicago, 1914-16.* Purchase.

American Railway Master Mechanics' Association. Proceedings, vol. XLIX. *Chicago, 1916.* Purchase.

The Ash in North Carolina. Press Bulletin no. 156, N. C. Geological & Economic Survey. *Chapel Hill, 1917.* Purchase.

Bibliography of Fishes. Volume I. Authors' Titles A-K. *New York, 1916.* Purchase.

Bibliography of Recent Literature on Flotation of Ores. January to June 1916. U. S. Bureau of Mines. Technical Paper 135. *Washington, 1917.* Purchase.

A Brief Description of the Physical and Operating Properties of the Subsidiary and Affiliated Companies of the General Gas and Electric Company, May 1915. *New York,* n.d. Gift of Chas. H. Armstrong.

Buyers' Guide for Textile Mills. A handy reference book for buyers of textile mill supplies and equipment. New York, n.d. Gift of Textile World Journal.

By-Product Coke and Gas Ovens for the Recovery of Ammonia, Tar and Benzols. Designed and built by H. Kopers Company. *Pittsburgh,* n.d. Gift of H. W. Nicolson.

Calculus. By H. W. March and H. C. Wolff. *New York, 1917.* Purchase.

Dutch East Indies. Jaarverslag van de Winning, het Vervoer en den Verkoop van Banka-Tin over het Exploitatiejaar 1914. *Batavia, 1916.* Purchase.

Electric Central Station Distribution Systems; their design and construction. Ed. 2. By H. B. Gear and P. F. Williams. *New York, D. Van Nostrand Co., 1916.* Price $3.50. Gift of Publishers.
The first edition of this work was published in 1910, and was based on articles in the Electrical Age. This new edition is due to the rapid progress in the last few years and has been largely rewritten.
W. P. C.

English and Engineering. A volume of essays for English classes in engineering schools. By Frank Aydelotte. *New York, 1917.* Purchase.

Federal Valuation of the Railroads in the United States. Statement prepared by H. C. Phillips, of the developments in connection with Federal valuation as of February 10, 1917. Gift of Clemens Herschell.

Feldspar in Canada. Canada. Mines Department, pub. no. 401. *Ottawa, 1916.* Purchase.

Gas Industry. vols. 11-21. *Buffalo, 1911-12.* Purchase.

Geology of the Country to the South of Kalgoorlie, including the mining centers of Golden Ridge and Feysville, Western Australia. Geological Survey, Bulletin no. 66. *Perth, 1916.* Purchase.

Grandes Voûtes. vol. 6. By Paul Séjourné. *Bourges, 1916.* Purchase.

Graphite, 1916. Gift of Joseph Dixon Crucible Co.

[illegible] State Geological Survey. Year Book for 1915. Administrative Report and [illegible] papers. Bulletin no. [illegible] [illegible], 1916. Purchase.

India Rubber, Gutta Percha and Electrical Trades Diary and Year Book, 1917. London, 1917. Purchase.

Institution of Civil Engineers. List of Members. 1917. *London, 1917.* Purchase.

Institution of Gas Engineers. Transactions, 1916. *London, 1916.* Purchase.

Manchester Association of Engineers. Transactions. 1915-16. *Manchester, 1916.* Purchase.

Manufacturing Costs and Accounts. By A. H. Church. *New York, 1917.* Purchase.

Marine Steam Engine. Ed. 13. By Richard Sennett and H. J. Oram. *London N. Y., 1916.* Purchase.

Master Car Builders' Association. Proceedings. vol. 50, pt. 1-2. *Chicago, 1916.* Purchase.

Metal Mine Accidents in the United States during calendar year 1915. U. S. Bureau of Mines. Technical Paper 168. *Washington, 1917.* Purchase.

Metropolitan Water Board. Twelfth Report on Research Work by A. C. Houston. *London, 1916.* Purchase.

Motor Cycling Manual. Ed. 3. *London,* n.d. Gift of Frank Gilliland.

National Association of Cotton Manufacturers. Transactions. No. 101. *Boston, 1917.* Purchase.

National Committee for the Prevention of Blindness. Annual Report, 2d, Nov. 1916. *New York, 1916.* Gift of L. Cammen.

National Lamp Works of General Electric Company. Abstract. Bulletin of Nela Research Laboratory Works. *Cleveland, 1917.* Gift of National Lamp. v. 1, no. 2.

New York (City) Department of Water Supply, Gas and Electricity. Communication from Commissioner William Williams to the Board of Estimate and Apportionment, transmitting report of Deputy Commissioner Wilcox upon the Citizens Water Supply Company of Newton, Borough of Queens, Feb. 5, 1917.

—— Report of Delos F. Wilcox, in relation to the Citizens Water Supply Company of Newton, Oct. 7, 1916. Gift of City of New York Department of Water Supply, Gas and Electricity.

New Zealand. Mines Statements for 1915. *Wellington, 1916.* Purchase.

North Carolina and her Natural Resources, some Facts and Figures. Ed. 2. *Raleigh, 1917.* Purchase.

North East Coast Institution of Engineers and Shipbuilders. List of Members. Feb. 1917. *Newcastle-upon-Tyne, 1917.* Purchase.

Oil Investigations in Illinois in 1916. Illinois. State Geological Survey. Bulletin 35. *Urbana, 1917.* Purchase.

Operation of Gas Works. By W. M. Russell. *New York, 1917.* Purchase.

Pennsylvania. Department of Agriculture. Proceedings of the Farmers' Annual Normal Institute. Bulletin 283. *Harrisburg, 1916.* Purchase.

Pennsylvania. Department of Mines. Report. Part I—Anthracite, 1915. *Harrisburg, 1916.* Purchase.

Physical Experiments for Engineering Students. By Samuel Sheldon and Erich Hausmann. Part I. Mechanics, Sound, Heat and Light. *New York, D. Van Nostrand Co., 1917.* Price $1.25. Gift of Publishers.

Prepared for sophomore students in the Polytechnic Institute of Brooklyn. There are thirty exercises, covering a course of ninety hours. W. P. C.

Pilot Butte Oil Field. Wyoming State Geologist. Bulletin no. 13. *Cheyenne, 1916.* Purchase.

Preliminary report on the Crystalline and other marbles of Alabama. Alabama Geological Survey. Bulletin no. 18. *University, 1916.* Purchase.

Quarry Accidents in the United States during the calendar year 1915. U. S. Bureau of Mines. Technical Paper 165. *Washington, 1917.* Purchase.

Railway Business Association. A Glimpse at the Works by Frank W. Noxon, Jan. 16, 1917. Purchase.

Railway Problem. Address by Frederick A. Delano, at the annual dinner of the Railway Business Association, Jan. 16, 1917. Purchase.

Refining and Utilization of Georgia Kaolins. U. S. Bureau of Mines. Bulletin 128. *Washington, 1916.* Purchase.

Russian Electrotechnical Commission. Standardization Rules of the American Institute of Electrical Engineers. In Russian. n.p. 1916. Gift of Commission.

Russian Electrotechnical Terminology. By L. D. Tsaxoff. Russian. n.p. 1916. Gift of International Electrotechnical Commission.

Russia. Scientific Committee of the Ministry of Agriculture. Bulletin of Bureau of Agricultural Mechanics. vol. 8, nos. 1-3. n.p. 1916. Gift of Committee.

Seaboard Air Line Railway Company. Annual Statement, 1909-1916. *Portsmouth, Va., 1909-16.* Gift of Company.

The Solution. Address by Alfred P. Thom, at the Annual dinner of the Railway Business Association, Jan. 16, 1917. Purchase.

Some Business Aspects of the Railroad Problem. Address by Walker D. Hines. Annual meeting of the Chamber of Commerce of the U. S. *Washington, D. C., January 31, 1917.* Purchase.

Springfield (Ill.) Insurance Department. Addresses and Papers on Insurance. By R. M. Potts. *Springfield, 1917.* Gift of Insurance Department.

Staffordshire Iron and Steel Institute. Proceedings. vol. 31. *Stourbridge, 1917.* Purchase.

Strength of Ships. By A. J. Murray. *New York, Longmans, Green & Co., 1916.* Price $5.00. Gift of Publisher.

An extensive treatise, largely mathematical, of the strength of beams, columns, shafts, bulkheads, plating, fastenings, rigging, and outboard fittings, plate brackets and rudders, as well as discussions of longitudinal and transverse strength. W. P. C.

System. vols. 11-28. *New York, 1907-1915.* Purchase.

Tables giving the Times of Rising and Setting of the Sun and Moon, 1917 and 1918. Supplement to the American Ephemeris, 1917. *Washington, 1917.* Purchase.

Tentative Valuation by Interstate Commerce Commission, Feb. 14, 1917. Elgin, Joliet & Eastern Railway. Gift of Clemens Herschel.

Thermodynamics of the Steam Engine and Other Heat-engines. Ed. 6. By C. H. Peabody. *New York, 1914.* Purchase.

The Toltz-Lipschutz Acetylene Car Lighting System. By Max Toltz. Gift of W. P. Cutter.

U. S. Bureau of Standards. Circular nos. 14, ed. 5; 16, ed. 4; 30, 35, ed. 2; 38, 3d. 2; 48-49, ed. 2; 51, 52, ed. 2; 53, 54, ed. 2; 55; 57, ed. 2; 59, 60.

—— Scientific Papers. nos. 267-8, 271-6, 278-9; 282-91, 293-5.

—— Technologic papers. nos. 25, 41, 70, 73, 76, 77, 79, 82. Purchase.

U. S. Bureau of Standards. Weights and Measures. 11th Annual Conference. *Washington, 1917.* Gift of Bureau of Standards.

U. S. Interstate Commerce Commission. Valuation in the matter of the property of the Atlanta, Birmingham & Atlantic Railroad Company, Georgia Terminal Company and Alabama Terminal Railroad Company. Hearing, Washington, Jan. 29-Feb. 3, 1917. Gift of Clemens Herschel.

Water Powers of Alabama, Second Report on. Alabama Geological Survey. Bulletin no. 17. *University, 1916.* Purchase.

Western Reserve University. Catalogue, 1916-17. *Cleveland, 1917.* Gift of University.

Who's Who in America. 1903-05. *Chicago, 1905.* Gift of Clemens Herschel.

A.S.M.E. Accessions

Atlantic Deeper Waterway Association. Report of Proceedings of 9th Annual Convention. *Philadelphia, 1917.* Gift of Association.

Detroit (Mich.) Board of Water Commissioners. Annual Report 64th, 1916. *Detroit, 1917.* Gift of Board of Water Commissioners.

Hawaiian Volcano Observatory. Weekly Bulletin. vol. IV, no. 11, 12. *Honolulu, 1916.* Gift of A.S.M.E.

Huddersfield Engineering Society. Journal of Proceedings. 17th session, 1915-16. *Huddersfield, 1916.* Gift of Society.

Inferences Concerning Auroras. By Elihu Thomson. Reprinted from the Proceedings of the National Academy of Sciences, vol. 3, Jan. 1917. Gift of A.S.M.E.

Johnson's Steam Vessels of the Atlantic Coast, 1917. New York, Eads Johnson Publishing Co., 1917. Price $5.00. Gift of Eads Johnson.

This handy volume contains a list of the steam vessels of American registry on the Atlantic Coast. The main facts are given in the list by companies or owners, an alphabetical index being furnished. W. P. C.

Mayor's Committee on Unemployment. Planning Public expenditures to compensate for decreased private employment during business depressions. Extension of an address by John R. Shillady. *New York City, 1916.* Gift to Mayor's Committee on Unemployment.

National Association of State Universities in the United States of America. Transactions and Proceedings. vol. 14, 1916. *Burlington, 1916.* Gift of A.S.M.E.

Walworth Log. February 1917.

PERSONALS

In these columns are inserted items concerning members of the Society and their professional activities. Members are always interested in the doings of their fellow-members, and the Society welcomes notes from members and concerning members for insertion in this section. All communications of personal notes should be addressed to the Secretary and items should be received by April 16 in order to appear in the May issue.

CHANGES OF POSITION

Lieut. Philip B. Eaton of the U. S. Coast Guard Cutter "Bear," San Francisco, Cal., is now stationed at the Naval Aeronautic Station, Pensacola, Fla.

Mark E. Smith, until recently affiliated with the Erie City Iron Works, Erie, Pa., as draftsman, has become associated with the Union Iron Works of the same city.

Frederick W. Starr, formerly connected with the Toledo Scale Company, Hartford, Conn., has become identified with the Fisk Rubber Company, Chicopee Falls, Mass.

T. E. Buck, formerly draftsman with the Donora Steel Company, Donora, Pa., has entered the employ of the United Engineering and Foundry Company, Springfield, Ill.

C. W. Hunting, recently vice-president and general manager of the Minneapolis and St. Louis Railroad, Minneapolis, Minn., has been elected president of the Virginian Railway.

James McNaughton, formerly vice-president of the American Locomotive Company, has been made assistant to the president of the Eddystone Munition Corporation, Eddystone, Pa.

Paul A. Fusselman, formerly general shop foreman of the Kansas City Gas Company, Kansas City, Mo., has become associated with the Counties Gas and Electric Company, Ardmore, Pa.

Waldo H. Blackmer has severed his connection with the American Ammunition Company, Worcester, Mass., and has become affiliated with The Harrison Radiator Corporation, Lockport, N. Y.

John R. LeVally, formerly engineer with the Burrell Belting Company, Chicago, Ill., has become affiliated with Armour and Company, Chicago, Ill., in the capacity of assistant chief engineer.

Harold B. Bernard has resigned his position with The Foxboro Company, Foxboro, Mass., to accept the position of mechanical engineer with the Oklahoma Petroleum and Gasoline Company, Tulsa, Okla.

Arthur Driver, formerly chief tool designer, Gray and Davis, Inc., Boston, Mass., has accepted a position with the Canadian Cartridge Company, Ltd., Hamilton, Ont., Canada, in the capacity of mechanical engineer.

C. J. Bacon has resigned his position as assistant engineer of construction with the Illinois Steel Company, South Chicago, Ill., to enter the engineering department of E. I. du Pont de Nemours Company, Wilmington, Del.

Norman L. Baker has become connected with the American Steel Foundries, East St. Louis, Ill., in the capacity of works engineer. He was formerly mechanical engineer with the By-Products Coke Corporation, Chicago, Ill.

George C. Vennum, until recently assistant chief engineer of the Union Electric Light and Power Company, St. Louis, Mo., has assumed the duties of mechanical superintendent of The Douglas Company, Cedar Rapids, Ia.

Harry D. Carter, until recently fuel engineer with Samuel M. Green Company, Springfield, Mass., has become affiliated with the Warner-Klipstein Chemical Company, Inc., South Charleston, W. Va., in the capacity of superintendent.

Robert B. Adams has resigned his position as assistant superintendent of the New England Westinghouse Company, Meriden, Conn., and has accepted a similar position with the King Sewing Machine Company, of Buffalo, N. Y.

Virgil A. Root has accepted a position in the engineering department of Warner and Swasey Company, Cleveland, O. He was formerly connected with the engineering department of the Subers Fabric and Rubber Company, Cleveland, O.

Kenneth I. Tredwell, until recently purchasing agent with The Sentinel Manufacturing Company, New Haven, Conn., has accepted a position on the production engineer's staff of the Winchester Repeating Arms Company of the same city.

Newman Comfort, manager of the Nebraska Division of the Universal Inspection Company of Iowa, Omaha, Neb., has assumed the duties of manager of the Ohio Branch of the National Workmen's Compensation Service Bureau, Cleveland, O.

John C. Hoar has resigned as master mechanic of the Chateaugay Ore and Iron Company, Lyon Mountain, N. Y., and has assumed the duties of general foreman of repair departments of the American Locomotive Company, Schenectady, N. Y.

Wallace H. Martin, until recently instructor of mechanical engineering at the University of Minnesota, Minneapolis, Minn., has become associated with the mechanical engineering department of The Pennsylvania State College, State College, Pa.

Theodore H. Hermanson, formerly superintendent of the Blake and Knowles Works of the Worthington Pump and Machinery Corporation,

[illegible] Cambridge, Mass., has assumed the duties of superintendent of [illegible] plant of Henry R. Worthington, Harrison, N. J.

George W. Rich, formerly works manager of The Aultman and Taylor Machine Company, Inc., Mansfield, O., has resigned his position and has accepted the position of assistant general factory manager for the Curtiss Aeroplane and Motor Corporation of Buffalo, N. Y.

H. J. Markey has left the hydraulic turbine department of The Wellman-Seaver-Morgan Company of Cleveland, O., and is now connected with the Firestone Tire and Rubber Company, Akron, O., in the special engineering department handling new plant construction.

Monroe R. Hull has resigned his position as chief engineer of the Arizona Copper Company, Ltd., Clifton, Ariz., to accept the position of mechanical engineer for the Sissert Mining Company, Ltd., with general office at London, and will be located at their properties in Russia.

M. William Ehrlich has become associated with the sales force of the Kewanee Boiler Company, with headquarters in New York. He was formerly connected with Hersh and Brother, heating and ventilating contracting engineers of Allentown, Pa., in the capacity of chief engineer.

Wallace J. Newell, formerly with the Westerman Iron Works, Seattle, Wash., is in the employ of the British Columbia Salvage Company, Vancouver, B. C., as engineer in the salvaging of the German S.S. "Sesostris" which went ashore off the west coast of Guatemala some years ago.

ANNOUNCEMENTS

Carl Eihrmann has become associated with the T B Gasoline Company, Chelsea, Okla.

James Stokoe has accepted a position with the Sinclair Refining Company, Chicago, Ill.

George W. Dunham has been elected a member of the board of governors of the Aero Club of Detroit.

Walter W. Hagerty has accepted a position with The Roessler and Hasslacher Chemical Company, Perth Amboy, N. J.

John J. Swan has been commissioned by the President as a captain of Engineers, in the Engineer Officers' Reserve Corps of the United States Army.

Palmer Collins, assistant superintendent of the South Works of the American Steel and Wire Company, Worcester, Mass., has severed his connection with the company.

Lieutenant Martin A. Doyle, formerly identified with the U. S. Coast Guard Cutter Mohawk, New York, is now stationed at Pensacola, Fla., Coast Guard Cutter Penrose.

Henry D. Sharpe, president of the Brown and Sharpe Manufacturing Company, Providence, R. I., has been elected a director of the New England Telephone and Telegraph Company.

R. B. Sheridan, president of the Allied Machinery Company of America, New York, left on March 2 for a business trip to Spain and France. He will be away for two months or more.

Cass L. Kennicutt, who for many years has been known as one of the foremost experts in water softening, has become associated with The Permutit Company, in charge of the Chicago office.

Clyde C. Elmes, superintendent of the Eddystone Ammunition Corporation, Eddystone, Pa., has been commissioned a captain in the Engineer Officers' Reserve Corps of the United States Army.

William H. Smead, manager of the heating and equipment department of the Austin Company, Bridgeport, Conn., has been transferred to the home office of the company, Cleveland, O., in a similar capacity.

H. Ralph Hadlow, formerly consulting mechanical engineer, Cleveland, O., has become mechanical engineer with The Watson Engineering Company, Cleveland, O., which has been incorporated to carry on the business of Wilbur J. Watson and Company.

George H. Woodroffe has accepted the position of mechanical and metallurgical engineer with The Parkesburg Iron Company, Parkesburg, Pa. He was formerly in the employ of the Philadelphia Steel and Forge Company, Philadelphia, Pa., as superintendent of the forge department.

Rolla C. Carpenter reaches the retiring age at the end of the present college year and will sever his active connection with Cornell University at that time. Professor Carpenter expects to maintain his activities in the fields of engineering investigation and research for several years to come.

Edwin G. Hatch, consulting engineer, of New York, is arranging to have manufactured in this country a large quantity of 5 per cent nickel steel turbine blades for the Victoria Falls and Transvaal Power Company, Ltd., of South Africa, whose plant serves the Rand Gold Mines. These buckets were, previous to the war, manufactured in Germany.

Stewart M. Marshall, formerly chief engineer of the Cambria Steel Company, Johnstown, Pa., and latterly chief engineer for the Southwark Foundry and Machine Company, Philadelphia, Pa., has formed a partnership with Charles Page Perin, to undertake consulting work connected with the iron and steel industry, with offices at 2 Rector Street, New York.

Benjamin F. Wood, for 16 years electrical engineer, Pennsylvania Railroad, and for the past three years vice-president and chief engineer of the United Gas and Electric Engineering Corporation, announces the organization of B. F. Wood, Engineers, Inc., New York. The new firm will investigate, design, construct and supervise engineering works in power development, transmission, railroad electrification, electric railway and lighting systems and industrial plants.

Gustaf Akerlund and George W. Semmes, formerly chief engineer and assistant chief engineer, respectively, of the Standard Gas Power Company, have established a consulting and contracting engineering business under the name of Akerlund and Semmes, with headquarters at 17 Battery Place, New York. The firm will specialize in gas producer equipment for power as well as for metallurgical and ceramic ware furnaces.

E. Howard Reed, vice-president of the Reed and Prince Manufacturing Company, Worcester, Mass., has enlisted for three months' service as an executive at the United States torpedo station, Newport, R. I., with the rank of a lieutenant commander in the United States naval reserve, thereby releasing one or more officers for active sea duty. Mr. Reed, who is rated in class 4, composed of experienced manufacturers, will be attached to the torpedo-making branch of the station.

APPOINTMENTS

Harold L. Green has been appointed resident manager of the Cleveland office of Scovell, Wellington and Company.

John A. Leach has recently been appointed mechanical engineer of the Minneapolis Steel and Machinery Company, Minneapolis, Minn.

William L. Batt, formerly sales engineer with the Hess-Bright Manufacturing Company, Philadelphia, Pa., has been appointed sales manager.

William L. Saunders of New York, chairman of the Ingersoll-Rand Company, has been appointed as Class C director of the New York Federal Reserve Bank.

Edward J. Kearney, secretary and treasurer of the Kearney and Trecker Company, has been appointed a member of the Wisconsin State Board of Industrial Education, by Governor E. L. Philipp.

AUTHORS

J. E. Johnson, Jr., is the author of a book entitled Blast-Furnace Construction in America.

Richard Moldenke has contributed an article entitled The Seasoning of Castings to the March issue of *The Foundry*.

Fred. M. Heidelberg is the author of An Ideal Changehouse, which appears in the March 3 issue of the *Engineering and Mining Journal*.

Percy H. Wilson, consulting engineer, of Philadelphia, has contributed an article entitled, Edison Portland Cement Plant Remodeled, to the March 3 issue of *Engineering Record*.

N. W. Akimoff is now completing a text book on Applied Hydrodynamics, which will be of the same general character and for the same grade of engineers as his recent book on Lagrange's Equations.

THE NEW BOOKS

ALL books received by The Journal will be listed under this heading, generally accompanied by brief descriptive notes. Works of special importance to mechanical engineers will be commented on at length by members and others peculiarly qualified by reason of their experience and training. In this issue are included two comprehensive reviews of recent works in cost accounting.

Cost Accounting and Burden Application

Cost Accounting and Burden Application. By Clinton H. Scovell, A. M. Harvard University; C. P. A. New York and Massachusetts, Assoc. Am.Soc.M.E., etc. Cloth, $5\frac{1}{4}$ x $7\frac{3}{4}$ in., xiv + 328 pp. D. Appleton & Co., New York, 1916. $2 net.

The author of this little book is a specialist in industrial accounting. He is of the modern school, recognizing the fact that cost accounts are of no value unless they are properly interpreted and made use of as one of the elements of scientific management. The book is not a systematic treatise, suitable for students, but is a logical discussion of general principles, criticizing the errors in belief of many of the old school of accountants. It should be read by practical accountants who wish to be informed as to the latest and best theory of their profession. Two of the controversial subjects in accounting theory are treated at great length: Interest Charged to Cost, and Methods of Applying Burden. As to the first the author gives a most convincing argument that interest on investment should be considered as a part of factory cost, taking issue with A. Lowes Dickinson, who presents the opposite view in his book Accounting Practice and Procedure. As to burden application, he condemns the percentage on wages, the percentage on labor and material, and the man-hour rate methods, and approves what he calls the "new machine-rate," which is called by most writers the "machine-hour rate." He shows the necessity of checking the burden charged to cost through the machine rate with the actual burden during corresponding periods, and exposes the unsoundness of the theory proposed by A. Hamilton Church in his book on The Proper Distribution of Expense Burden, and his "supplementary rate" by which the total burden during a period is charged to the cost of the goods produced during that period. The author states the correct principle as follows: "Only a part of the total burden is chargeable to the manufacturing cost of the product made during periods of curtailed production, the part chargeable being the same percentage of total burden as the curtailed production is of the total production."

In a footnote Mr. Scovell seems to claim that he was the discoverer of this principle, and states that he made practical application of it in 1911. The present reviewer, however, used it in 1909 in a works with which he was then connected, not suspecting that it was anything new, and in reviewing Mr. Church's book in *The Iron Trade Review* of Feb. 4, 1909, condemned the supplementary rate and advocated charging a machine with the same burden throughout the year, irrespective of the fluctuations of business conditions outside of the shop.

In a chapter on Unearned Burden the author describes the correct method of treating it in these words: "Monthly cost reports show comparatively the amount of unearned burden, indicating the tendency of business conditions. [It may, however, indicate bad shop management, by which some of the machines are unnecessarily idle.] This unearned burden may either be charged off each period to Loss and Gain or a reserve may be accumulated out of profits during busy times to which the unearned burden may be charged during time of business depression." Special chapters are devoted to discussions of Foundry Costs, Textile Costs, Candy Costs and Paper Manufacturing Costs.

In the interest of good English it would be well for the author in his next edition to avoid the use of the word "inventory" (p. 91) in the sense of "materials" or "stores" and confine it to the dictionary meaning, and on page 50 to change "data" to "datum."

William Kent.

Manufacturing Costs and Accounts

Manufacturing Costs and Accounts. By A. Hamilton Church. Cloth, $5\frac{3}{4}$ x 9in., 452 pp., 139 illustrations and 4 folding plates. McGraw Hill Book Co., Inc., New York, 1917. $5.

Mr. Church's immediate purpose is to define the "why and wherefore," the mechanism, and the operations of cost accounting, and to make clear the relations of cost accounting to general accounting. His further intent is to enable the cost accountant on the one hand and the general accountant on the other each to understand and appreciate better the importance of the other's work.

He is therefore concerned wholly with the principles of costing, their application under the three methods of expense distribution later defined, and the nature and proper use of factory cost reports. He does not attempt to describe any specific cost-keeping system, and indeed expressly disclaims any intention or desire of so doing.

The province of factory operations in which the cost accountant works, Mr. Church discerns as an intermediate term in the series by which business generally transforms money into goods, goods into sales, sales into cash again. That is, in a merchandizing enterprise we have the cycle

Cash—purchases—sales—accounts receivable—cash.

The function of the general accountant is to record, separate, classify, and summarize all the details of these transformations, using therefor the standard media—the journal and ledger—conveniently subdivided when a large business is to be handled.

In a manufacturing proposition the cycle becomes

Cash—purchases—*factory operations*—sales—accounts receivable—cash.

The cost-accountant's province includes the whole region of these intermediate changes. He must keep with each item of material, labor, and expense therein an account similar to that which the bookkeeper maintains with each customer and item of cash. He should assume control where the general accountant leaves it at the factory gate, maintain it until the finished product is ready for delivery, and connect his records with the main accounts, of which they form a specialized and detailed subdivision.

His peculiar problems arise from the fact that different items of the purchases (i. e., material) may be justly charge-

[illegible] different fractions of the collateral outlay for overhead and expense, and may be in very various stages of completion when a balance is to be struck, and the difficulties thus created increase enormously with the diversity of manufactures carried on in the plant.

Mr. Church sets himself the task of describing the art by which these problems are solved, and of outlining approved practice in dealing with the subjects, situations, and transactions met in actual cost keeping work.

He begins with a survey of the mechanism of accounting and of cost accounting, the elements of cost, and the means for connecting cost with product. He defines three methods of charging direct labor and expense: *A*, by departmental hour cost; *B*, by hourly burden or percentage of wages; *C*, by scientific machine rates. He distinguishes further three degrees of subdivision of the unit quantity to which cost may be applied—entire departmental output, definite lots, and individual pieces or parts. He recognizes finally two degrees of detail practicable in determining the departmental cost of any unit—i. e., all departmental processes may be lumped as a total, or each process costed separately. He then outlines the processes of costing by each of the three primary methods *A*, *B*, and *C*, and concludes Part I by a discussion of the common problems of waste, scrap, by-products, depreciation of small tools and equipment, and selling expense.

Part II takes up the actual operations of purchase and production, the departmental activities involved, the standard system of accounts as usually necessary and common to all cost work, and the books, forms, blanks, etc., used for records common to all systems. Four chapters out of the twenty-four in this part are devoted to special forms peculiar to the three primary methods of allocating expense already referred to as *A*, *B*, and *C*, and the last three chapters deal with the collecting of departmental costs and general considerations affecting cost keeping. Part III discusses the nature, scope, and preparation of factory reports and returns.

Of the 140 illustrations in the book, about one-fourth are diagrams tracing the relations between accounts, and the course of items of cost in their passage from original entry to the final controlling account. The remainder are typical rulings and printings for the various books, sheets, cards, schedules, and other forms requisite in standard cost-accounting practice as defined by the author.

Mr. Church appears to have achieved his declared purpose to approach his subject from an angle and by a method different from any foregoing attempt, and to present a survey of the general structure of cost accounts free from detailed description of any specific system of cost keeping. It is open to question whether the view he gives is "comparatively simple," or indeed whether any simplicity, even comparative, can be given to such a conspectus. Ready comprehension of his subject matter, and even of his diagrams, seems to presuppose a familiarity with the processes of general accounting and the phenomena of manufacturing that comes only after long experience with more elementary aspects. The book is hardly one for student beginners. On the other hand, no degree of proficiency is likely to be so great as to put a practitioner beyond the capacity for finding interest and profit in the volume. Certainly, mature minds exercised in the problems appearing along the field of contact between factory production and commercial accounting will find in it suggestion, explanation, and direction obtainable, so far as the reviewer knows, nowhere else.

CHARLES BUXTON GOING.

Strength of Ships. By Athole J. Murray. 5½ x 8¾ in., 400 pp., 218 diagrams, 3 folding plates and many tables. Longmans, Green & Co., New York, 1916. $5 net.

In this book, which is said to be the first in the English language to be exclusively devoted to the subject, the author has aimed to include all available information in the field of the strength of materials which has a special application to the design of the structure and fittings of vessels, as well as some of the recently published research work of shipbuilders. The thirteen chapters following an introductory section deal respectively with stress, strain, and elasticity; materials of ship construction; beams; columns; shafts; longitudinal strength; transverse strength; watertight bulkheads; strength of plating; fastenings; rigging and outboard fittings; plate brackets; rudders.

The Marine Steam Engine. By the late Richard Sennett, Engineer-in-Chief of the Navy; Fellow of the Royal School of Naval Architecture and Marine Engineering, etc., and Sir Henry J. Oram, K. C. B., F. R. S., Engineer-in-Chief of the Fleet; Engineer Vice-Admiral, etc. Longmans, Green & Co., New York. Thirteenth edition, 1916, 6 x 9 in., ix + 502 pp., 414 illustrations. $6 net.

In the last two editions of this well-known work—first issued in 1882, much matter has been added to the chapters dealing with the steam turbine, the torsion meter, and the internal-combustion engine, to take account of their rapid development and increasing importance in marine engineering.

Electric and Magnetic Measurements. By Charles M. Smith. 5 x 7¾ in., 373 pp., 171 illustrations. The Macmillan Co., New York, 1917. $2.40.

This course, which has been developed from the author's lecture and laboratory notes, presupposes on the part of the student a year's study of general physics and some knowledge of the calculus. The 56 laboratory exercises which are given are so described that particular types of apparatus are not called for unless they happen to be well known and generally available.

Pipe and the Public Welfare. By R. C. McWane. 5 x 7½ in., 165 pp., 77 illustrations. The Stirling Press, New York, 1917. $1.

After a brief historical sketch of the use of pipe from the earliest days, the author describes the methods used in manufacturing cast-iron, wrought-iron, and steel pipe. A third chapter gives much technical and historical information on the deterioration of metal pipe and canvasses the relative merits of the wrought and cast forms. The final chapter, of 21 pages, is devoted to wood-stave pipe.

The John Fritz Medal. Embossed boards, 6 x 9 in., 98 pp., 14 illustrations. Obtainable from the Secretary, John Fritz Medal Board of Award, Engineering Societies Building, New York City. $4.

The John Fritz Medal is a gold medal presented for achievement in applied science as a memorial to the great engineer whose name it bears. The John Fritz Medal Board of Award, appointed by the four great national engineering societies, has published this handsome volume—from the Bartlett Orr Press, giving a history of the medal, the rules governing its award, biographical sketches and portraits of the thirteen medallists, and the names of those who have served on the Board of Directors and the Board of Award from the establishment of the medal, in 1903, to the present.

The Taylor Society announces that its next meeting will be held in Syracuse, N. Y., May 18 and 19.

SPRING MEETING PAPERS

THIS country is now in a war of great magnitude and far-reaching results. It is a war of brains and has resolved itself into a contest putting the utmost demand on the ability of engineers to organize and direct the industries which constitute the vital forces of the nations involved. Two and one-half years of the war have emphasized this truth. One of the most potent requirements for a successful issue is an ample and sufficient output of war material from engineering workshops. To bring out the results of valuable experience in munitions manufacture, which has been obtained by many engineers through the period of war, and to make these results available to all, professional sessions of the Spring Meeting of The American Society of Mechanical Engineers will be devoted to the various phases of the subject. Papers to be presented at these sessions are printed in comprehensive abstract below.

Other important professional features of the Spring Meeting, to be held in Cincinnati, May 21 to 24, are sessions on Machine Shop Practice, Gas and Steam Power Subjects, and Protection of Industrial Workers and also a Joint Session with the National Machine Tool Builders' Association for the consideration of papers on Employees' Service Work and Industrial Education. Abstracts of papers to be presented at the first three of these sessions are also published in this issue. The topics at the Joint Session will be introduced in the form of addresses without previous publication.

MUNITIONS PAPERS

THE Committee on Meetings, in arranging for sessions at the Spring Meeting on the subject of the Manufacture of Munitions, desired to obtain a general discussion of the basic problems involved, which have to be met and solved to ensure success in the quantity production of arms and ammuition. The brief papers which follow are in the nature of introductory discussions, designed to draw out further discussions on such fundamental questions as Financing, Organization, Manufacturing Principles, Special Machines, Essentials for Quantity Manufacturing, Procuring Materials, Specifications, Limits and Tolerances, Gages and Inspection. The sessions will be entirely informal, and all members who have had experience in munitions manufacture are urged to attend and contribute to the common cause.

Following the papers is a bibliography of current articles on munitions production which have appeared during the past eighteen months.

MUNITIONS CONTRACTS AND THEIR FINANCING

By FREDERICK A. WALDRON, NEW YORK, N. Y.

Member of the Society

THE manufacture of munitions is a strictly engineering proposition in which the functions of the engineer dominate. Had engineering methods been employed in the initial stages of the work in the past two years, instead of "corner grocery" methods of beating down in price for the sake of letting the contract at an advantageous figure, the profits in many cases would have been far in excess of what they are today.

Few people realize the penetration of financing into the bone and sinew of our national existence. In the daily routine of life, with the majority of people receiving a stipulated income by the day, week, month or year, the intricacies and risks involved by those providing the money to pay this income are seldom if ever thought of.

The forces set in motion by signing a contract, large or small, penetrate and accelerate industrial and natural resources.

In the last two years wonderful progress has been made in the development of resources hitherto thought to be remote or inaccessible, and the education and training of men in the allied industries has developed at a rate heretofore unknown. Why this sudden development? Why such an exhibition of human energy, both mental and physical? It was dire necessity, and necessity knew no master.

Money or currency is the visible medium of exchange, and if there is no money or other recognized medium of exchange, man resorts to primitive methods and fights for existence.

With the advent of contracts amounting to millions, few manufacturers, if any, at the beginning of the war, fully realized the time that would be required to deliver the materials. Not only this, the amounts involved were staggering. It has now become customary to converse in terms of millions of dollars instead of dollars and cents. Further, the difficulties of the problems, such as sub-contractors failing to perform, the increased cost and difficulty of transportation, the obtaining of tools, equipment, materials, and labor, for the fulfillment of these contracts, were not anticipated.

With these conditions, which are now in retrospect, many industries are charging off deficits of considerable size to experience in the manufacture of munitions. Few have made fair profits. Some have made abnormal profits.

With the foregoing as a matter of history, the question as to how the Allied Nations obtained their credit would be extraneous to the subject. This brings the question before us for discussion as to how the contractor is to receive his money promptly and regularly for his work.

It is sufficient for the manufacturer to know that the work which he is to do will be regularly and promptly paid for, and any risks taken by him to produce in quantity within the time specified are to be amply protected by an advance of money sufficient to cover the expense of preparation.

For presentation at the Spring Meeting, Cincinnati, Ohio, May 21 to 24, 1917, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. The paper is here printed in abstract form and advance copies of the paper may be obtained by members gratis upon application. All papers are subject to revision.

Undoubtedly the cause of failures in the delivery of munitions of sufficient quantity within the time specified, is directly traceable to the lack of judgment in the amount of money demanded as advance payment, combined with a lack of business and financial management.

If we review carefully the ratio of the amounts advanced to the total amount of the contract and its time of completion, it will be found that in no case has a sufficient advance been made to enable the contractor to finance this work on the same basis as he would adopt in the conduct of his regular business.

WHAT IS FINANCING?

Financing is providing the coin of the realm in adequate and opportune quantities for the purpose of obtaining an object desired. Where ready cash is not available, the usual way of providing the coin of the realm is by the issue of mortgages, bonds or notes, which are papers promising to pay at maturity the amounts advanced, with interest of course for the use of the money, payable at specified periods during the time for which the loan is made.

All mortgages, bonds or notes must have tangible and preferential security, rights, etc. These principles cover the salient points necessary for a government, corporation or individual to obtain the necessary amount of money to pay for the object to be obtained.

Documents given by the party wishing to obtain the object (called the Owner or Purchaser) to the party who is to provide the object (called the Contractor or Vendor) are in the form of leases, contracts, or purchase orders, supplemented by specifications and drawings, or samples of the object desired.

Prior to the signing and exchange of these documents, the money which the purchaser wishes to use to attain his object has been provided. Upon the signing and exchange of these documents, the details are planned for distributing this money in adequate and opportune quantities in order that the object to be attained may be completed as rapidly as possible and the contractor provided with sufficient funds to promptly and efficiently complete his work.

If a purchase order or contract exceeds a certain amount and covers a definite period of time, a bond is required in order to protect the purchaser.

On large munitions contracts, the bonds of sub-contractors are marshalled by the general contractor and deposited as security. This is to indemnify the purchaser against loss. In fact, the bond is the purchaser's insurance to secure him against failure to complete the work, or the dissipation of moneys paid by the purchaser to the contractor as an advance payment. A bond is also required by those financing the work.

ADVANCE PAYMENTS

1 When and how met
2 Amount in percentage of the total amount of the contract
3 Rate of liquidation
4 Interest charges.

PAYMENTS ON ACCOUNT

1 When to be met. Depends on:
  - *a* Resources of contractor
  - *b* Volume and rate of delivery of material
  - *c* General progress of work
  - *d* Complete information.

2 Amount of payments:
  - *a* Purchase value less a certain percentage for reserve or adjustment at end of contract
  - *b* A purchase value or agreed amount to liquidate advanced payments.

3 Type of payments:
  - *a* Sight draft, check, notes or bonds.

FINAL PAYMENTS AND ADJUSTMENTS

1 Adjustment of percentage held back on part payments
2 Adjustment of debits and credits during the progress of the contract
3 Type of funds:
  - *a* Notes, bonds, sight drafts, checks.

DISCUSSION OF ADVANCE PAYMENTS

In manufacturing and contracting requirements, it is a well-known fact that from three to five turnovers of inventory per year are essential to a reasonable profit.

The general contractor, on a large munitions contract, has to provide in turn advances not only to the sub-contractor, but he must also be able to take advantage of the market, and oftentimes buy materials long before they are required. He has also to meet the payments for materials of sub-contractors furnished long in advance of the time they are to be used. Then, again, contracts have been let to some small concerns who have failed to fulfill the requirements of the contract. This also applies to the larger sub-contractors and, as has been the case, it is necessary for the general contractor, in order to protect himself, to take control of the entire properties of the sub-contractor on an entirely different basis and under entirely different conditions. This involves delays not ordinarily estimated in the contemplation of the work to be done.

A further necessity for ample and proper financing during the progress of the contract, is that assembling contractors be supplied with a sufficient number of component parts of proper quality in order to complete the work.

It is quite possible (in fact, it has happened) that manufacturers of component parts have held up shipments awaiting payments on their materials. To my knowledge, this has involved at different times delays in the completion of work valued at from one to three million dollars over a period of time of from two to five weeks, which, if figured on the basis of six per cent, would mean a loss to the general contractor of from $4,000 to $12,000 on interest charges alone.

But, beyond all of this is the demoralizing effect on a sub-contractor and the discouragement which he experiences. This reacts upon the organization, and in a very short time the enthusiasm and efficiency of the personnel of the plant have rapidly deteriorated.

Then, again, the question of financing depends to a large extent upon the government with which the general contractor is dealing. With some there is no trouble, and businesslike methods are used in the handling of all financial transactions. There are others, however, that are exceedingly troublesome and irregular in meeting their financial obligations and, while they are good for the money obligated, the irregularity and slowness of payments oftentimes creates suspicion and distrust on the part of the manufacturer, with a corresponding demoralization.

After an observation and experience of two years in this work, the writer feels safe in assuming that an advance of at least 25 per cent is necessary and 33 1-3 per cent would

leave a sufficient margin of safety, with good management.

It is not necessary that all of this amount be paid upon the signing of the contract, but it should be available for drawing upon as occasion might require.

The rate at which advance payments should be liquidated is a matter which can only be adjusted to the requirements of the case in hand. A good rule to follow is to deduct from each invoice the same percentage of this invoice as would liquidate the advance payment upon the completion of the contract. It is customary, in some contracts, to deduct an additional ten per cent as an adjustment fund to protect the purchaser at the completion of the contract.

Interest charges are sometimes demanded on advance payments, but the usual practice is to dispense with this charge.

PAYMENTS ON ACCOUNT

Payments on account depend on the resources of the contractor, volume of business, rate and quality of materials delivered, general progress of the work, and complete audit information as to the financial condition of the contractor.

The amounts of these payments are generally made on the invoice value of the materials shipped, less deductions for the liquidations of the advance payments and insurance to the purchaser.

The types of payments usually made are either cash on receipt of the bill of lading or sight draft; or settlements at certain defined periods, either by the week, semi-monthly or monthly; sometimes, thirty days from the receipt of the invoice, bills of lading or inspectors' certificates.

Where the financial standing of the company is such as enables it to have cash on hand or available to conduct its business, payments are taken in bonds or short-term notes of the government for which the work is being done.

FINAL PAYMENTS

Final payments should be made as promptly as possible upon the completion of the contract. It is hardly possible, in the majority of contracts, to make these final payments promptly, as it oftentimes involves the adjustment of debits and credits for expenses on the part of the contractor and rejected work or spoiled materials on account of the purchaser. It is essential, therefore, in order to have a prompt adjustment, that a close check be kept on the progress of the work at all stages and a clear and definite method of maintaining records be kept by both the purchaser and the contractor.

The types of funds used in final payments are the same as those used for payments on account.

ORGANIZING FOR MUNITIONS MANUFACTURE

By ARTHUR L. HUMPHREY, WILMERDING, PA.

Member of the Society

THE task of organizing a plant to undertake the manufacture of munitions is one of many factors. In fact, organizing involves all of the items in the general list: specifications, materials, designing, limits, gages, inspecting, etc.

For presentation at the Spring Meeting, Cincinnati, Ohio, May 21 to 24, 1917, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. Pamphlet copies of this paper may be obtained by members gratis upon application. All papers are subject to revision.

The general success of the undertaking is dependent upon the perfection of the working organization, upon the selection and installation of adequate machines and other tools, and upon the careful planning of the work, which is not limited to that within the shop alone, but involves a consideration of the market, the purchase and delivery of supplies.

The financing accomplished, the task of organizing comes next in order. Their work done, the financial backers of the undertaking become impatient to see deliveries made because of their failure to understand the mechanical and human problems in the task of organizing, and a net loss is the result of insufficient time being allowed for perfecting the working organization, equipping for and planning the work. Haste makes waste in most affairs and it is not the exception here. A premature beginning may result in an encounter with conditions which will mean an entire revamping of the whole scheme—conditions which would have been determined and provided for had sufficient time been given for careful planning and making schedules complete in every detail from start to finish.

It is quite essential that an organization for the manufacture of munitions be built around a nucleus of men who have had experience either in munition making or in work of an allied character. With such a group as a basis, it is comparatively easy to place new men and ramify the organization into the various departments and divisions, each properly correlated with the other. It should be so arranged that each department acts as a unit within itself and attends to but one thing, such for instance as manufacturing the shrapnel time fuse and that alone.

Many operations in the manufacture of munitions cannot only be as well done by women as by men, but are better done by female help. These operations are such as involve light, delicate work, requiring deftness and dexterity in the use of the fingers. Therefore, such work should be segregated at every opportunity and the organization be made to include the requisite number of women.

The work to be accomplished is first revealed by the specifications submitted. Conferences between the engineers and shop foremen should be held at frequent intervals as the planning and scheduling progress in accordance with the results demanded by the specifications, and the whole problem should in this way be thoroughly "threshed over."

This problem of organizing is closely bound up with that of equipment. The condition of the machinery market and the urgency of the contract will determine largely the type of machines installed. In every case, where possible, automatic or semi-automatic machines should be given preference in order to get maximum accuracy with a minimum skill requirement on the part of the operators. This reduces materially the losses due to error of the individual. Careful consideration should be given to every detail of the manufacture, a thorough time study made, and the most logical sequence of operations worked up and scheduled before decisions are made as to the types of machines to be installed. Too much stress cannot be placed upon this feature, for any changes it may be necessary to effect after the machines have been ordered will result either in considerable loss or inefficient manufacture. Grouping of the machines should also be gone into very carefully to avoid unnecessary handling between successive operations.

Great emphasis must be placed on the necessity for a well-organized and well-equipped tool room. It is of paramount importance to have an unstinted supply of gages, jigs, machine fixtures and other special tools, for these are needed in great number in the manufacture of munitions. They are, in

fact, indispensable to the successful quantity production of accurate work.

Also, upon the inspection department will depend the proper utilization of the gages supplied by the toolroom—in other words, the inspection department and the toolroom are links in the same highly important chain of accuracy. A carefully organized inspection force must check the product not only at the end, but at each successive stage of manufacture. The product must be checked not only for variations in dimensions but for chemical and physical properties as well. The personnel of the inspection force is of the utmost importance, for it is quite unwise to give the power of rejection to a group of uninformed inspectors who are lacking in judgment. And if power to reject be withheld, the inspection force might well be entirely dispensed with.

Other points of interest in this general connection may be found in the writer's paper on The Mobilization of Material and Industrial Resources, read before the Engineers' Society of Western Pennsylvania on May 31, 1916.

ORGANIZATION FOR MUNITIONS MANUFACTURE

By HARRY L. COE, BOSTON, MASS.

Member of the Society

I HAVE approached the subject from the viewpoint of a manufacturer already engaged in a metal-working business, and have tried to suggest some of the factors which he should consider if he expects to produce projectiles. Assuming that the manufacturer has ample financial resources, adequate equipment, a satisfactory source of raw materials, etc., what type of an organization is essential to the successful production of munitions: and among the various kinds of munitions, what articles can the particular plant produce economically?

Much time and effort will be wasted if this double process of selection is not given attention. The characteristic optimism and confidence of the American manufacturer, coupled with the strong desire to be of service to his country, or to make money, lead many firms into making persistent efforts to get munitions contracts which should, logically, go to firms of an entirely different character and facilities.

Before looking for a munition contract, there should be an honest self-analysis. It isn't a question of "can my shop produce this piece?" but "can it make this piece as well and as economically as anyone else?"

Many firms having a good manufacturing organization will feel that they require only a little additional equipment. To these people I say, "Beware!" Three years ago they might have had as good a chance of success as anyone, but today they will have to compete with the firms which have not only the organization but the proper equipment as well.

On the other hand, they may have a general equipment which can be adapted to munitions, but their shop and executive organization may not be trained to think and act along the lines of specialized mass production. And here again I say, "Beware!" Difficult, slow and expensive though it may seem to start from nothing and equip a complete munitions plant, it is much more difficult, slow, and expensive to develop and get into effective operation the organization which will make this kind of a business successful.

For presentation at the Spring Meeting, Cincinnati, Ohio, May 21 to 24, 1917, of The American Society of Mechanical Engineers. The paper is here printed in abstract form and advance copies of the paper may be obtained by members gratis upon application. All papers are subject to revision.

CHARACTERISTICS WHICH MUNITIONS PLANTS LACK

We turn with pride to our great industries,—the steel corporation, our railroads, etc.—and feel that certainly the American genius and ability which has made them possible can turn out unlimited quantities of shells. And so they can, *if they have time.* Unfortunately for the manufacturer, this element of time is of the greatest importance to the fighting units. The advantage lies with the side which first gets the necessary supplies.

The big, centralized organizations are the result of a slow process of evolution, and while their working force may be constantly changing, one finds that the habits and traditions of the work are maintained, and it is this force—habit and tradition—which is entirely lacking in the munitions business. To produce shells economically, this force must be generated in and by the organization, which means embodying in that organization a certain proportion of picked men, chosen because they possess these habits, or who, because of their versatility and training, can quickly acquire them. Such men are not easy to find and the time it would take to get *enough* of them together in one place to make a large organization successful is almost a fatal handicap.

It would seem, therefore, that the greatest success would be obtained by comparatively small units specializing in one type of munitions. One may say, "Why not have a big shop departmentalized, with a case shop here, a shell shop there, time fuses or primers in another section, etc.?" Theoretically, this would be all right, but if one studies the organizations which have tried this in the past few years, he will find a tremendous amount of lost time, effort and money. In other industries where this principle has been successfully developed, I believe there will be found quite a percentage of men in each division who have grown gray-haired with years of service along that particular line.

This condition does not obtain today with respect to the munitions business. Before the present year the firms manufacturing projectiles in the United States were very few. The orders placed by our Government outside of its own arsenals were so small that even at the high figures paid they offered no attractions to anyone to develop a business along these lines. As a rule, the training in the arsenals has not fitted men to produce the best results under our existing industrial conditions. At the present time the arsenals are not letting any of these good men get away. In general, the attitude of the War Department has not encouraged the development of this industry except in the cases of a few manufacturers, as mentioned above. The result is that there is a very limited field from which to draw either workmen or executives "skilled in the art."

It would seem, therefore, that the manufacturer must build an organization around such of his men as possess the proper habits and training, and they in turn will have to see to the development of the manufacturing units. Here, again, large and complicated units do not develop rapidly, and in them mistakes are tremendously expensive and slow to correct.

The manufacturer should therefore take stock of his organization carefully. If it does not contain men whose habits of thought and training are consistent with specialization of processes and mass production, it lacks one of the prime factors in successful munition manufacture.

ADAPTABILITY OF PLANT TO PRODUCT

If, on the other hand, the organization *is* of this type, he should look carefully over the wide range of articles classified

as munitions and select something which is as similar as possible to his regular product in size, material, and general nature.

We hear of gray-iron foundries making strenuous efforts to get contracts for producing cartridge cases, when the nearest thing they have to a press is a plate-molding machine and they never had an opportunity of running to capacity on a single pattern for more than a few days at a time. Needless to say, if such people are so unfortunate as to get a contract, it is almost certain to prove an expensive failure for them and may result in a serious shortage of supplies for the fighting line.

Assuming now that there is an organization which is accustomed to specialization and that a type of munitions adapted to the available equipment has been selected, what subdivision should be made in the organization and what functions should be performed by each?

In the first place, it is futile to try to handle a projectile department as an appendage to some other part of the business. It is a business in itself and its success or failure will probably depend on the completeness with which every detail is worked out and checked.

This is a product in which duplication inside exceedingly small limits is essential. Moreover, if one agrees with the theory of specialization mentioned above, the type of munitions manufactured will be limited to a few pieces, or even to a single piece, of the same nature. The size of the order should be large enough so that even the smallest working unit —man or machine—can be employed constantly on the same operation. Under such conditions no detail is so small but that it pays to give it careful attention. Every motion will be repeated many times an hour, and the expense due to trivial losses will soon reach large proportions. Realizing this and knowing that this is a temporary business, many firms have gone outside of their regular force and employed special managers to look after their projectile manufacture. This has been their sole function and the arrangement was terminated when the order was completed.

The internal mechanism of the organization, then, might be classified somewhat as follows:

1 General Service Department
2 Diplomatic Staff
3 Production Department
4 Inspection Department

1 General Service Department

Under the General Service Department, we find

a Records and accounting (with special prominence given to control of manufacture rather than to details of cost finding)
b Purchasing and stores organization
c Designing, drafting and experimental development
d Protection and safety (with special reference to destruction by representatives of the enemy's government and to the safeguarding of unskilled workers).

With reference to these general departments, it may be safe to modify our general principle of entirely separate organizations. Whether or not these departments are combined with the existing departments employed in similar work will depend somewhat on the volume of the work both in the normal business and in the munition contract, as well as on the physical layout of the plant. In most cases it is possible so to plan that this work will follow the practice developed for the regular business and can be absorbed by the department already doing this kind of work.

With reference to the purchase and stores of the department, there are no special features which differ to any marked degree from ordinary practice.

2 Diplomatic Staff

While this organization will be small, it is none the less important. If the munitions are for a foreign government, there will undoubtedly be foreign representatives stationed at the plant as receivers. These men are not accustomed to our methods. Their temperament is entirely different from the people we are ordinarily meeting. Possibly they do not speak our language. If sufficient attention is given to them, and their points of contact with the organization limited as far as possible to a few chosen men, it will be much easier to reach a practical working basis and to prevent expensive and often unnecessary misunderstandings and delays.

This department is responsible for seeing that these receivers are provided with the information they desire and that it is presented to them in such a way that they get a correct impression of the conditions. If they appreciate the difficulties which may be arising and the action the organization is taking to eliminate causes of trouble, it naturally affects their attitude toward the plant.

The diplomatic staff sees to it that any instructions issued by the receivers are transmitted to the proper department so that they go into effect.

Through this department, the shop can approach the receivers for information or rulings on conditions which may not be clear.

Even in the cases of work for our own government, I believe such a department is advisable. The fewer people who have official relations with these receivers, the less the chance of contradictory instructions or of false or unnecessary information or misunderstandings.

3 Production Department

Under the Production Department comes

a Maintenance of equipment
b Operation of equipment
c Selection and training of workmen
d Tool and gage production
e Establishment and operation of wage payment and penalties systems

This department is responsible for maintaining production and developing economy, and has full control of all agencies which bear directly on the operation of equipment.

Maintenance of equipment has been included under this department for two reasons: First, it brings the time element of repairs largely under its control. Much loss of production can be avoided by a careful and frequent inspection of machines and transmission. A few hours in [illegible] may save days of shutdown later. And, second, because the men who make up the maintenance crew are usually the general group of millwrights who see to the location and setting of equipment, which again is a direct corollary of production. When breakdowns occur, operations have to be readjusted and it is often more economical to take an idle machine out of a battery and replace with a spare than to interrupt the flow of product. Such work is obviously up to the repair gang.

In this connection I am inclined to think that twenty hours per day is about the economical limit to run machines under the conditions of forced production usual on this work. The

requiring four hours for repair—a most excellent instance.

Having given the production chief the means of supplying the working force with equipment to use, we must turn to a study of the workers.

Because of the difficulty of getting skilled mechanics, it has been necessary to develop that type of an organization which can produce results with the average workman in the shortest possible time. This is one of the reasons why it is well to subdivide the operations into simple elements and eliminate complex machines. Because of the very nature of the class of workmen available, it is necessary to make the most out of a continually changing force. This has been done successfully by selecting from the better grade of men a class which might be called *tool setters* or *machine starters*, and giving them charge of a battery of machines. This builds up a secondary line of defense, as it were, and it is possible to develop a fairly permanent organization of this kind of men. Behind these machine starters come the group foremen, assistant superintendents, etc.

For somewhat the same reasons the tool and gage manufacturing department is made a part of the production chief's organization. I say tool and gage *manufacturing* department instead of tool room advisedly, for it has to be a real manufacturing department with the demand for flat cutters, boring bars and heavy supplies of special tools which immediately occurs when one starts to reach maximum output on single-operation machines. The good tool maker is not as a rule a production man and it is a difficult thing to get a tool room into the spirit of manufacturing.

The method of wage payment for all these men is immaterial provided a maximum incentive is given to each man. Personally, I am in favor of a thorough piecework system, as it is simple for the workmen to understand and not expensive to operate. However, premium or bonus plans are all right if the rewards are immediate. The setting of standards is an important part of the wage basis and the opportunities for the competent operation and time-study man are wonderful. He, too, is part of the production chief's organization.

In this connection, while in general the theory of penalties is not desirable, it has been found that it is a good balance wheel to the continuous insistence put on production, especially where the workmen are not trained in the true spirit of machine shop existence and often are only transients with very little interest in the quality of their work.

4 Inspection Department

The work of the Inspection Department comprises

a Inspection of operations
b Intermediate inspection
c Final inspection

To some it may seem that at least part of the inspection organization should be directly under the chief of production: for example, the first or operation inspection which occurs between each operation. I believe, however, that better results and a more consistent and thorough inspection will ensue by creating a staff of inspectors responsible to their own chief to handle all inspections wherever they occur. It is easier to train men for these jobs and instil into them the necessary standards of work and habits of thought and action if they are included in a branch of the organization which is all their own.

Assuming that the complete inspection is organized into a department of its own, it may well develop according to the following scheme:

If the work has been subdivided so that operations occurring on individual machines are simple, it is possible to station back of each group of machines an inspector or inspectors and gage every piece for the controlling dimensions. We might class these inspectors as *operation inspectors*. It is their duty to see that each piece produced falls inside the tolerances which are allowed.

As the work progresses and a series of operations are performed upon a piece, it is often found desirable to have an *intermediate inspection*, as in many cases the later operations materially change the form of the piece so that it is impossible to check the work previously done. It is usually found desirable to set aside a certain part of the shop for this purpose and have all the product delivered to the inspection room.

This intermediate inspection is a general overall check on the production reported by the operation inspectors. The advantages are obvious when considered from the payroll point of view.

When a piece is finally finished and ready for presentation to the receivers, either of our own government or of a foreign government, there should be organized a thorough *final* inspection. Under this final inspection, all dimensions possible are checked and in general the same procedure as may be instituted by the receivers is followed out. In case the product does not come up to the standard, it is either sent back for repairs or else set aside and presented as a special batch with full explanations to the receivers. In this way the shop establishes a very desirable basis of fair play with the receivers and, as a usual thing, the policy results in the granting of special limits to cover slight deviations from specifications, which, if sent through with the other work, might arouse suspicion and work to the detriment of the shop.

In connection with the inspection organization, it is very necessary that an ample gage-checking force be organized. All working gages should be checked at least once a day and, in case of some of the finer type of gages, it may be necessary to check oftener if the standards are very exacting.

PROCURING SPECIAL MACHINES FOR MUNITIONS MANUFACTURE

By H. V. HAIGHT, SHERBROOKE, QUEBEC

Member of the Society

In asking for an introductory paper on the subject of the manufacture of munitions the Committee on Meetings suggested that the writer might "analyze the different types of machines required and indicate whether it is better to buy them or to make them."

As no two manufacturers of munitions follow the same methods or use the same machines, any opinions the writer may advance must be based on his own experience or observation and will be subject to confirmation or modification when compared with the experience of others. A few words as to the basis of the writer's experience will, therefore, be in order.

The firm with which the writer is engaged is machining and assembling the 18-lb. British shrapnel and the British 8-in. howitzer shell. Under the plan of organization of the Canadian Imperial Munitions Board, the work is all sublet by the board. The contractor for machining and assembling

For presentation at the Spring Meeting, Cincinnati, Ohio, May 21 to 24, 1917, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. The paper is here printed in abstract form and advance copies of the complete paper may be obtained by members gratis upon application. All papers are subject to revision.

shrapnel, for example, is furnished with forgings for the bodies, with finished component parts such as disks, sockets, copper bands, tubes, tin cups, bullets, etc., and with the other materials required such as resin, solder, paint and shipping boxes. The following notes, therefore, cover only the machining and assembling of the above two sizes of shells which will be taken up separately. In addition to the experience mentioned, the writer has visited many shell shops both in Canada and the United States.

EIGHTEEN-POUND SHRAPNEL

When undertaking the first contract for shrapnel our firm had a machine shop which could be converted to shrapnel production and an experienced working force. As shrapnel production increased and as the regular work picked up, additional machines were purchased or made, until all the regular tools had been withdrawn from shrapnel production. In many cases these regular machines were withdrawn because required for producing the regular product; but there was the additional reason that for four-fifths of the operations the new tools purchased or made were more productive than the regular tools used at first. Our experience, therefore, has covered the use of standard machine tools, special purchased machines and special machines made by ourselves.

The following notes relate to the principal operations on the shrapnel and the machines which our experience shows were the best to use. Fig. 1 shows the shell at several stages and the numbers indicate the operations described below.

1 *Cut off open ends.* Standard 4-in. cutting-off machines with air expanding mandrels. Production 900 in 8 hours. We also tried a special machine to cut off both ends at one setting and another machine of the type of a pipe-threading machine, but both proved failures and were returned to the makers. On the regular machines the air mandrel is preferred to the universal chuck as it is much quicker and costs less to keep in repair.

2 *Rough turn body.* We used at first heavy 24-in. engine lathes, 24-in. Gisholts, Lo-swing lathes, etc., with fair results, but we are now using single purpose lathes of our own make which produce more work and are much simpler to keep in repair. These lathes have cast iron spindles, $6\frac{1}{2}$ in. in diameter in the front bearing, with driving gear integral with the spindle. They have tight and loose pulleys on the back-gear shaft, thus eliminating countershafts with their troubles. The feed is by belt, eliminating feed-gear troubles. The work is chucked on an air expanding mandrel and turned with a bar cam to give the necessary enlargement at the open end of the shell for the subsequent bottling.

3 *Rough face base.* We have used 36-in. engine lathes, 42-in. and 60-in. vertical boring mills, 36-in. planers, 30-in. planer-type millers, etc., on this work, but have abandoned them all for 4-in. standard cutting-off machines. On milling machines the tool upkeep is too great, on planers the work is hard to hold, on planers and boring mills the intermittent cut is hard on the machines and on all except the cutting-off machines, the labor cost and upkeep are too high. On the cutting-off machines the regular universal chuck is omitted and a plain hinged chuck used, as a universal chuck will not stand shell work. The regular cutting-off tool blocks are replaced with a tool block to hold a facing tool. When the countershaft clutch pulleys give out, they are replaced with tight and loose pulleys. Each man runs two of these machines.

4 *Finish face and turn base.* Standard 16-in lathes, with air collet chucks supported by steady rests give satisfactory service on this operation. Only hand feeds are used.

5 and 6 *Rough and finish bore.* It has been found best to rough bore on one machine and finish on another. Turrets are not desirable on shell work, where they can be easily avoided. We used a well-known make of turret lathes on this work, but they proved pretty light and required considerable repair. They were eventually withdrawn for regular work and replaced by special boring lathes of our own make, in which the work is held inside the spindle by an air collet chuck. Two different feed mechanisms are in successful use, one a central rack with power feed and air return, the other a crank and "Scotch Yoke" with hand feed. Another Canadian munitions plant made very successful boring machines from gasoline engine patterns. We built a double spindle lathe for this work but it proved a failure.

7 *Rough band groove.* This work is being done on cutting-off machines and also on lathes of our own make. In both cases

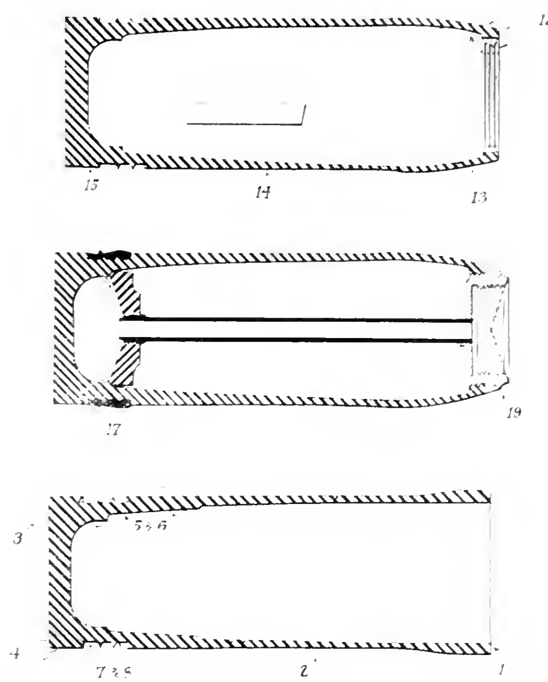

FIG. 1 INDEX OF OPERATIONS OF MACHINING SHELL

the work is held in push-out air collet chucks. No longitudinal feed is required and only a hand cross-feed.

8 *Finish band groove.* This consists of undercutting the edges and forming the waved ribs. Potter and Johnston automatics are in successful use and stand up well. It has been found, however, that a man can do more work on one machine than he can on two or three, so the automatic feature is of no use on this work. Regular 20-in. engine lathes with special fixtures, and simple lathes of our own make with similar special fixtures, are now preferred as they produce rather more work. This is the only operation on which universal chucks are still used, but they will probably be superseded by air chucks. Two different purchased waving machines, built for this purpose alone, were tried but proved unsuccessful.

9 *Harden.* We used at first muffle furnaces, with cast-iron pot muffles holding eight shells, but now we use large semi-muffle furnaces, holding 50 shells. The furnaces are built to designs furnished us by another shell manufacturer, but appear to be copied from a commercial furnace. We used pyrometers at first, but now the operators go by color. An "Irite" pyrometer is used to train new men.

10 *Bottling.* The nose of the shell used to be heated by dipping in a pot of lead. This was rather expensive in the use of lead, and also gave a little trouble from lead poisoning. The present method is to heat in an oil furnace having holes through which the shells project into the furnace. A water jacketed front was tried, but the brick with iron thimble has been found better. We built these furnaces after the style used in another shell shop. The bottling presses used at first were air presses which we made ourselves from drill sharpeners, but the present practice is to use geared crank presses which are purchased. After bottling, the shell is put back in a similar furnace to anneal the nose.

11 *Shot blast.* The regular foundry sand blast was used at first, but present practice is to use a small shot-blast machine of our own make. This has two jets, one of which cleans the band groove and the other the base. The shot blast gives practically no dust, and can be used anywhere in the shop.

12 *Turn and thread nose.* This requires a fairly heavy turret lathe, and we are using both 24-in. engine lathes, and also single purpose lathes of our own make, both of which are equipped with turrets. We prefer the latter lathes as they take the work inside the spindle and eliminate the steady rest. Air collet chucks are used. This is the only operation on the shrapnel where a turret is used and this requires five holes of the turret.

13 *Grind nose and* (14) *Grind body.* Standard grinders, slightly modified for the wide wheels used on shell work, give satisfactory results, as do also special purchased shell grinders. The grinding machine manufacturers, of all the regular machine tool builders, come out with the greatest credit from the viewpoint of shell production. In most other cases, the shell manufacturers themselves have built more suitable machines than either standard or special machines built by the machine tool manufacturers.

15 *Grind base.* Simple machines of our own make give good results.

16 *Press copper band.* Two different hydraulic hand presses, both designed and built by other shell manufacturers, are giving good results on this work.

17 *Turn band.* A heavy engine lathe with special equipment and an air collet chuck gives good results, but costs more money than a very good special band turning lathe, built by another shell manufacturer.

18 *Fill.* This is nearly all home-made equipment and hardly requires detailed description here.

19 *Turn socket.* A 16-in. engine lathe is heavy enough for this. A clutch on the back gear is convenient. A turret is not desirable.

20 *Paint.* We use with satisfaction a small portable machine of our own make, driven by a $1/6$ hp. motor.

The foregoing does not cover the use of purchased single-purpose lathes, of which there are now a large number of designs on the market, but from experience with three or four types of these on 8-in. shells, it appears that they should give good results on shrapnel work. The features they should have would be a large spindle, 4-in. to 5-in. diameter, with hole at least $1\ 3/16$-in., strong drive and feed, a good feed-engaging clutch, or better still a drop worm. The countershaft should have tight and loose pulleys, though the use of air chucks will largely eliminate countershaft troubles, as it is not necessary to stop to change the work. It is better, however, to have tight and loose pulleys on the headstock and eliminate the countershafts, as they take up so much room overhead that it is difficult to group the machines to best advantage. The elimination of countershafts also reduces the cost of belting, which is quite an item. A special point for consideration is the depth of dovetail on the carriage, for the cross slide. This should be $1\frac{1}{8}$ in. to $1\frac{1}{4}$ in. deep, but there are at least two of these lathes on the market with dovetail $3/8$-in. to $1/2$-in. deep, and a taper gib. The very small surface is not sufficient to resist the side strain of a cam, which is used on two of the operations, and the height is not sufficient to use a straight gib with set screws. It is usually necessary to replace the regular cross slide with a special cross slide, and when doing so it is much simpler to use a straight gib with set screws, rather than a taper gib.

To sum up, a manufacturer starting to make shrapnel would be well advised to consider the following suggestions:

a Do simple operations and use simple machines. Do not try to do several operations at one setting, and do not buy automatics, turret lathes or other complicated machines.

b A pretty safe and satisfactory plan is to get a quick start at some fraction of full intended capacity and to add equipment and build up production after some experience has been gained.

c Suitable purchased machines for making a quick start would be regular cutting-off machines, regular engine lathes 16-in. to 24-in. swing, simple single-purpose lathes, regular or special grinders and such special machines as bottling presses, band presses and band lathes.

d It will be worth while to consider the organization of a lathe building department to supply many of the machines required to increase the capacity. This department might also undertake the making of air chucks, waving devices and other special attachments, and thus relieve the tool room. Later, this department would become a repair department, which is an important and busy department when work is being pushed day and night.

[The author concludes his paper with a brief description of the operations on 8-in. howitzer shells.]

PRACTICAL WARTIME SHELL MAKING

BY LUCIEN I. YEOMANS, CHICAGO, ILL.

Member of the Society

SO many utterly foolish statements have been offered the public in regard to the manufacture of munitions and the possibility of this or that automobile factory or implement works, or other equally ill-adapted shop, being turned upon very short notice into a shell factory, that it seems well to consider of how little value for the manufacture of munitions is the present equipment of the average shop.

It should be emphasized that outside of the already existing munitions plants, the old equipment which manufacturers brought to the new business of shell making consisted mostly of their money, their credit, and the nucleus of an organization. Even the old floor space was infrequently used. The machinery and tools were more than ninety per cent new and it is significant that the greatest success has been made by those companies which were not even owners of machine shops of any kind.

It is well for the mechanical engineers and the manufac-

For presentation at the Spring Meeting, Cincinnati, Ohio, May 21 to 24, 1917, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. The paper is here printed in abstract form and advance copies of the paper may be obtained by members gratis upon application. All papers are subject to revision.

turers to review carefully accepted methods of munitions production and to ascertain just what time-honored precedents may be abandoned, what "red tape" may be cut, what traditions of the mechanic arts are sacred but unnecessary, where the corners may be cut and the result attained economically, directly, and without delay.

It would seem ridiculous to construct an office building of steel and terra cotta for the field headquarters of an army division, but we see nothing strange in the equally ridiculous proposition of a nicely built permanent factory for the comparatively simple operations of machining shells.

There is a strange twist in our mental conception which permits an engine for one purpose to be nicely housed in a pressed-brick and tile-lined structure, while another equally expensive and nicely made engine may be properly located on the open deck of a vessel, entirely unprotected from the weather. It is the same deference to tradition that makes us assume that machine tools must be guarded from every exposure, and we fail to see readily that their performance would be equally good for unusual service if they were heavily coated with rust on every idle surface.

The suggestions made here for emergency factory construction are to be understood as applicable strictly to emergency conditions and to meet a demand for an unusual amount of ammunition with the least possible delay and in no way as suggestions for permanent, private or Government arsenal construction.

First must be considered locality with reference to labor supply and transportation. Within easy reach of all our large centers of population may be found level, unoccupied, naturally well-drained acreage that is suitable for the purpose and that is gridironed by railroads. These are the sole requirements for such a plan.

The essential difference between this method and the conventional one is in the assumption that this particular machine work is no more an indoor occupation than is carpentry, brick laying, car repairing, or structural ironwork, and that in such emergency it should promptly be decided that outdoor equipment is satisfactory.

Final inspection, cleaning, painting, tool making, etc., would be provided for in fully enclosed buildings at the delivery end of the plant; but the large part of the work would be performed with the lightest kind of shelter over machines, operators, and transfer track, and in the opinion of the writer circumstances would not always justify even this.

The dimensions of the plant should be determined by the size of shell to be manufactured, and units of a given hourly capacity would be located between, and perpendicular to, two lines of railroad siding at the ends of the plant. One track would be entirely a receiving track and the one at the opposite side a shipping track. The distance between the tracks would represent the proper length of each unit to avoid congestion and afford the simplest movement and transfer of product.

The number of units required, as so determined, would establish the other general dimension of the plant.

Assuming that the shell was to be the well-known British 9.2-in. high-explosive and the required output 250 per hour, the general dimensions of the plant would be approximately 1000 ft. long by 300 ft. wide, and it would contain six units each capable of producing 42 shells per hour.

Each unit, commencing at the rear of the plant, would start with an unloading platform and extend in a double row of opposed machines for the different operations toward the finishing end, where the machinery installation would be replaced by hand operations and inspection, to the packing and shipping track.

From the end of the machine installation to the finishing end a single-story shelter would be built to house these operations and also the tool maintenance sections.

All machine tools would necessarily be horizontally belted, but since space is not considered, the convenience of having all transmission machinery within easy reach is a consideration.

In the construction of the plant, lines of concrete piers would be located to carry the line shafting, storm water drains would parallel the lines of piers, concrete foundation walls for the machine tools would come next, and transfer tracks intermediate the machine foundations.

Throughout the length of each machine-foundation wall would extend a cutting compound drain to a sump and pump at the end of the line or at intermediate locations. From each concrete pan under or at the machines would extend a chip channel, having a slightly raised bottom, connecting with chip tanks sunken in the ground and covered, but readily removable by the cranes.

Between each two rows of machines would be an industrial railway upon which would be operated platform cars for transfer. At each machine would be car-floor-height platforms from and to which all tools and material would be transferred.

Such a complete plant could be erected and operated to capacity within 60 days from the time authority was given to build it.

The purpose of this paper is to invite discussion, suggest a practical departure from the conventional and present a method of emergency construction that it is hoped will be of some benefit.

A complete series of machines for all shell-making operations could be designed along lines that would permit of their construction in immense quantities within 30 days from the time when the necessity for them arose, and at a rate of output that would supply any conceivable demand within the following 60 days.

The United States Government could easily be prepared to deliver such machines in the desired daily quantities within 30 days by the following method:

In each selected industrial center establish a Government storage plant in which would be stored the necessary patterns, jigs and equipment to make such machines; and in which would also be kept a list of the plants in the territory equipped to make the required parts. Upon order from Washington the patterns would be shipped to the designated foundries and, beginning with the third day, castings would be received at the rate of one casting a day per pattern. It would probably require about three weeks to manufacture the various working parts of the machine, but within 30 days at the outside, completed machines would be ready to run in the munition plants. The number of machines added to the equipment daily would be the same as the number of patterns from which castings were made. This record could be bettered by stocking in the warehouse the various machine parts, aside from the large bed castings, sufficient to make up machines of a desired daily output during the period found necessary. If this were done completed machines could be delivered to the munition plants within a week of authorization by the government.

Ten such manufacturing centers could be established, as for example, Philadelphia, Cleveland, Cincinnati, Buffalo, Pittsburgh, Minneapolis, Milwaukee, Birmingham, St. Louis, and Chicago, and within 30 days each unit could be producing shell-making machines at the rate of from 10 to 40 machines

000, depending on the size and nature of the machine being produced. Moreover, the total cost to the U. S. Government for the patterns, jigs, and equipment necessary for such a day would be approximately but $1,000,000.

MUNITIONS DESIGN FOR QUANTITY MANUFACTURE

By J. E. OTTERSON,[1] NEW HAVEN, CONN.

This paper deals with the question of the relation of design to quantity manufacture, with particular reference to the problem arising from the undertaking of quantity manufacture under abnormal conditions, and especially by manufacturers who may not have previously manufactured the particular product in question.

The term *design* must be broadly and specifically defined, and will here be taken as including not merely the general conception of the particular product which might be termed the *inventive design*, but also the full consideration by the designer of all questions affecting the design, manufacture, and service. It is obvious that the design must lend itself to abnormal manufacturing conditions. The term *design* will, therefore, be here understood as including the determination of all the limiting conditions which will permit the product to fulfill the purpose of the design.

Quantity manufacture should not be undertaken when the design is in the experimental stage. Models and samples should first be made and thoroughly tried out to the satisfaction of the designer, the manufacturer, and the consumer. Such models should embrace the limits of tolerances and thus serve to test the judgment of the designer in establishing such tolerances.

It is essential that the designer and the manufacturer recognize in full their respective responsibilities. The designer is responsible for the proper functioning of the completed product, provided it fulfills the specifications set forth in the design. The manufacturer is responsible for fulfilling the specifications set forth in the design.

The designer should make his design and specifications so clear, precise, and complete as to preclude any possibility of subsequent misunderstandings as to the exact intention of the design and as to the responsibility for any failure to function.

Standards of design should be absolute and not relative, expressed in terms of standard units of measurements and not in terms of relative exactness involving personal opinion and judgment as to the relations existing.

Designs for quantity manufacture usually prescribe some requirements as to interchangeability, and presuppose a system that is commonly called *interchangeable manufacture*. The term *interchangeable*, as frequently used, is indefinite and relative, and should not be used by the designer as a save-all to care for omissions from the specifications or as a substitute for the exact and absolute expression of the requirements of the design in terms of standard units of measurements. The term *interchangeable* has some significance as evidence of broad intent and general purpose, but is so lacking in exactness as to form no satisfactory basis for contractual or other obligations. It is, therefore, a dangerous term and should be used only in a supplementary sense.

Interchangeability increases in difficulty of attainment in ratio to the complexity of the product, the volume of manufacturing, the continuous operation of equipment, the abnormal and rush conditions in manufacturing accompanying national emergencies, the employment of unskilled and untrained labor and of labor having natural qualifications lower than those desirable for the work in hand. We must recognize that cutting tools lose their edges and exact form through wear, that machines do not continually remain in exact alignment and adjustment, that materials do not run absolutely uniform, and that the human element is a variable one. By reason of a combination of adverse conditions, absolute interchangeability may be impossible of attainment.

The designer must recognize, therefore, that peace-time standards of exactness cannot be maintained under war conditions, and that the standards of a factory that has been making a given article over such long and continued periods of time as to permit of the tuning of material and the training of personnel to exact repetitive performances, cannot be applied to the factory that must expand its facilities manyfold over night and deal with untried equipment, processes, and personnel.

In peace time the designer may quite properly seek to establish standards with such restricted tolerances as to enforce a high engineering standard, in order to preclude all possibility of failure of his design, and insure the success of his own work by placing a greater burden of accomplishment upon the manufacturer; but where the problem is one of production for war, the interest of the individuals must give way to the common good, and they must recognize a common purpose free of all antagonism and give each other all the tolerance that is possible, with the provision of a satisfactorily functioning product under urgent adverse conditions.

The problem before the designer of products for quantity manufacture under such conditions is, therefore, to give the manufacturer as *wide latitude* as possible without embarrassing the functioning of the product, and the suitability of the design to quantity manufacture under war conditions may properly be measured by the extent to which it meets this requirement.

It is recognized that this places upon the designer a decidedly heavier burden than is ordinarily assumed by him, but it is necessary that this should be the case if the design is to lend itself to the most rapid manufacture under the adverse conditions presumed.

This can best be accomplished by establishing as an essential part of the design a definite system of gaging, including the determination of gaging and holding points the control of which will control the functioning of the product, and prescribing tolerances at such points that are possible of attainment under the abnormal conditions of manufacturing under discussion.

It is the practice of some designers and manufacturers to prescribe exact dimensions as between two gage points and to establish no tolerances in connection therewith. The intention is that the manufacturer shall work as near to the absolute measurements as possible. Obviously this establishes no standard whatever. Since it is impossible to work to exact measurements, it places an unreasonable burden upon the manufacturer, who must assume the responsibility of prescribing the tolerances and instructing his help, permitting them to prescribe the tolerances according to their own judgment—obviously a loose method of operation. Every gage point should, therefore, have the tolerances clearly defined by the designer and these tolerances should be acceptable to the manufacturer, and, once accepted, should be adhered to. To

[1] Winchester Repeating Arms Co.

For presentation at the Spring Meeting, Cincinnati, Ohio, May 21 to 24, 1917, of The American Society of Mechanical Engineers. The paper is here presented in abstract form, and advance copies of the paper may be obtained by members gratis upon application. All papers are subject to revision.

prescribe tolerances less than required for proper functioning is uneconomical, since it demands unnecessarily exact operation and enforces extreme inspection practice, with consequent unnecessary rejections and reworkings.

Absolute requirements or measurements are justifiable only as applied to unimportant points or parts, where it may be safe to leave the question of tolerances to the judgment of the operator or of the inspector. In other words, we apply absolute measurements to those points about which we are not particular; where exactness is required tolerances should in all cases be provided in connection with the design.

In addition to providing a workable system of gaging, the designer must give consideration to materials and processes of manufacture. The materials prescribed by him must be such as to be readily obtainable in the broadest possible market under the abnormal conditions existing. It is important that the specifications for materials provide as great latitude as practicable, and that no restrictive requirements be included which will unnecessarily prevent the use of commercial material. In addition, the materials prescribed must not present any serious difficulties of working nor place an unnecessary limit upon cutting speeds, nor unnecessarily increase the consumption of cutting tools.

The responsibilities of the designer and the manufacturer are further defined by consideration of the problem of inspection. Inspection should be of two kinds and for two purposes:

a *Process Inspection*—the inspection of the work in process to determine the satisfactory performance of the operations; and

b *Product Inspection*—the inspection of the completed product to determine its satisfactory functioning qualities and its acceptability for the purpose for which it was designed.

The process inspection is obviously the responsibility of the manufacturer, and is his assurance that his manufacturing facilities are performing according to the standards set, his guide for the correction of manufacturing errors and shortcomings, and his protection against the rejection of the completed product.

The product inspection is obviously the responsibility of the organization that is going to use the product, and is at once an inspection of the design and of the manufacture.

If, in connection with the product inspection, the product should be found not to function properly and yet pass a satisfactory process inspection—that is, come within the tolerances laid down by the designer—the responsibility is obviously with the designer, and the adjustment must be between him and the consumer of the product.

PROCURING MATERIALS FOR MUNITIONS

By C. B. NOLTE,[1] CHICAGO, ILL.

After the first two months of the present war General French, of the English Army, said: "The problem set is a comparatively simple one—munitions—more munitions—always more munitions." The General's statement is undoubtedly true to a large extent at least, as it has been brought home to us that munitions certainly do constitute a most important problem in a war of any magnitude; but there are probably many manufacturers in this country today who will not exactly agree as to the simplicity of the problem.

The United States is exceptionally fortunate, however, in the possession of extensive and valuable deposits of the principal metals and materials for explosives required for manufacturing munitions. Of the world's supply, this country normally produces approximately 40 per cent of the coal and iron, 60 per cent of the copper, 65 per cent of the petroleum, 32 per cent of the zinc, and 33 per cent of the lead. It is apparent, therefore, that our domestic supply of the most important raw materials is ample for the manufacture of artillery ammunition, guns, cartridges, and vehicles which probably constitute the class of munitions that is required in the greatest quantity.

The United States Government arsenals are entirely inadequate, in time of war, to supply the needed products for war use, and this duty will fall, to a large extent, upon private industries. The amount of munitions that has been supplied during the war is no criterion of the amount that can be produced in this country. Many concerns that have participated in this new industry built entirely new plants for that purpose in order not to interfere with their increasing domestic trade. In addition to innumerable smaller manufacturers, there are over 35,000 manufacturing and equipment concerns in this country, each doing an annual business of over $100,000. Almost every industrial plant has operating equipment suitable for producing some munition part.

The manufacture of shrapnel and other shells does not require special machinery, and car-building and car-material plants, motor-car factories, and forge and machine shops are equipped to participate in this work. Watchmaking, typewriter, printing-machinery, office-equipment, scientific-apparatus, and electrical factories, as well as many other small machine shops, have been readily adapted to the manufacture of shrapnel and high-explosive fuses. The majority of machinery and locomotive manufacturers have machined shells. In addition, car and locomotive builders can construct field kitchens, ammunition wagons, gun carriages, and conveyances. Optical and jewelry factories are producing sights, aiming devices, and periscopes.

It requires more special machinery to produce small arms and small cartridges satisfactorily, but even interesting and surprising resourcefulness has been exhibited in the manufacture of these in ordinary plants.

Only powder manufacturers, however, are able to make the necessary explosives. The most important materials used in explosives today are obtained from coal tar, a by-product of coke ovens. Coal tar and its derivatives are produced principally by the various steel companies, and whereas there was but one concern recovering benzol and toluol before the war began, nineteen concerns had constructed new plants for this purpose by the end of 1915.

The motor truck has proved [illegible] part of army equipment; but [illegible] the many pleasure-car factories, with their ever-increasing outputs, are readily converted into motor-truck factories. Aeroplanes, most important for fire-directing, are now being made upon a commercial basis in this country by over twelve firms. In addition, there are over forty factories producing a small number of machines of some special or experimental type which can be standardized in wartime. On account of the short actual flying life of the aeroplane, however, it will

be necessary to adopt extreme measures to bring the production to a satisfactory figure.

Since, strictly speaking, munitions include all supplies and equipment necessary in war, with the exception of men and money, only the characteristics of the more important materials can be considered within the limits of this paper.

The gun proper of the usual field gun is subjected to a suddenly applied pressure of from about 35,000 to 40,000 lb. per sq. in. and is generally made of nickel steel of over 90,000 lb. per sq. in. tensile strength, 60,000 lb. per sq. in. elastic limit, and an elongation in 2 in. of 18 per cent. Rigid inspection and tests of this material are necessary before it is worked. The artillery wheels, springs, hollow axles, and recoil cylinders of field guns are made of ordinary materials used at automobile wheel factories and forge plants.

The two principal types of projectiles are the shrapnel and high explosive shell. The shrapnel body is not intended to break or explode when subjected to an internal pressure of about 20,000 lb. (the force exerted when the charge leaves the shrapnel), and is made of steel with a yield point of from 80,000 to 100,000 lb. per sq. in. Further, American shrapnel must, when finally treated, give a tensile strength of, in some types, 110,000 and others 120,000 lb. per sq. in., with an elastic limit of 80,000 lb. and 90,000 lb. per sq. in., elongation in 2 in. of 15 and 16 per cent. and reduction in area of 40 and 45 per cent, respectively. Steel for this purpose is furnished by the steel mills, and contains carbon from about 0.35 per cent to 0.45 per cent, manganese 0.50 to 0.80 per cent, phosphorus and sulphur not over 0.04 per cent each, chromium 0.70 to 1.20 per cent, vanadium 0.12 to 0.24 per cent.

Shrapnel steel, as produced by the large steel mills in this country, is furnished in three different forms: rough-turned bars, forgings, and rolled-steel rounds. The latter form has been used with considerable success and exceedingly rapid production.

The ordinary shrapnel fuse is made of several brass parts, the material for which can be produced by modern brass foundries. The usual composition of this material is about 59 to 61 per cent copper, 37 to 39 per cent zinc, and about 2 per cent lead, resulting in a tensile strength of about 45,000 lb. per sq. in., elastic limit of 27,000 lb. per sq. in., and 30 per cent elongation in 2 in. The fuse bodies and caps are generally forged, whereas the timing rings and other parts can be cut from brass tubes. The brass cartridge cases which hold the propelling charge for the shrapnel are drawn from brass disks cut from bars rolled by the various brass rolling mills. There is nothing unusual in the specifications for cartridge-case material, copper varying from 66 to 73 per cent, according to different purchasers' specifications, with zinc from 27 to 34 per cent, and with a tensile strength from 43,000 lb. to 54,000 lb. per sq. in. and an elongation of from 28 to 32 per cent in 2 in. The usual specification allows a range of 3 per cent in the copper and zinc contents; for example, 69 to 72 per cent copper and 28 to 31 per cent zinc.

The high-explosive shell is made of steel and is intended to break into a large number of pieces upon impact and explosion. It is unusually forged from steel rounds, billets, and cast ingots, with carbon from 0.40 to 0.55 per cent, manganese 0.40 per cent. to 1.00 per cent, phosphorus and sulphur not over 0.04 on 0.06 per cent each, and silicon from 0.18 to 0.30 per cent. Some of the steel for this purpose also contains nickel not to exceed 0.50 per cent and copper not over 0.10 per cent.

This grade of steel is easily produced by practically all of the large and small steel mills in this country, and, in fact, has been produced already in considerable quantities for such purposes. The fuse for the high-explosive shell does not present the same difficulties as that of shrapnel and is usually made of ordinary steel and copper alloys.

The first problem in the procuring of shrapnel, high-explosive shells, fuses and cartridge cases, is the delivery of suitable raw material. Care must be taken, therefore, to secure steel and brass of the proper chemical composition and physical characteristics. In addition to a careful study and understanding of the specifications and drawings, one of the most effective and economical means of obtaining the desired material rapidly and without excessive loss has been found to be by inspection of the material at the rolling mills before it is shipped to the finishing plants, by an experienced and trained organization.

Regarding explosives, the majority of commercial explosives are not suited for use in shells on account of their inability to withstand, without explosion, the shock of firing from the gun. Smokeless powder is produced by special plants which treat cotton fiber with such materials as nitric and sulphuric acid, alcohol, and ether. Nitrogen, used in the manufacture of nitric acid, is chiefly derived from the sodium nitrate found in Chile, but European nations are now obtaining a large amount of nitrogen from the air by the fixation process. Pyrites for making sulphuric acid is found in this country, although much of the best is imported from Spain. The United States manufactures ether and alcohol in abundant quantities. Glycerine, a by-product of soap manufacture, is produced in large amount at home. Cordite, the explosive which has come into such great favor because of its combination of propellant and high explosive qualities, is obtained by further treatment of gun cotton and nitro-glycerine with acetone, which is a product of wood distillation and which is also obtained from a special fermentation of starch. Trinitrotoluol is obtained by nitration of toluene, which constitutes about 36 per cent of crude benzol, a by-product of coke ovens.

Trinitrotoluol possesses an explosive force of about 119,000 lb. per sq. in., while the explosive force of picric acid is about 135,000 lb. per sq. in. Owing, however, to its propellant qualities and the fact that it does not form dangerous salts by combination with iron and other metals in contact, trinitrotoluol is superior to picric acid as a war explosive. Picric acid does yet, however, play an important part in priming compositions and propellant powders. It, too, is obtained from coal-tar derivations.

Although, as has been outlined, the United States is well equipped to furnish the principal materials for munitions, it is apparent that there are many other phases of the problem which it has not been possible to consider here. If the requisites of war are to be successfully met, every industrial worker, whether he be engaged on the farm, in the mine, or in the factory, has an important task to perform; every manufacturing plant has a definite obligation; and all the resources of our country must be systematically brought to their utmost utility.

LIMITS AND TOLERANCES FOR THE MANUFACTURE OF MUNITIONS

By A. W. ERDMAN,[1] SCHENECTADY, N. Y.

THE purpose of this paper is to direct attention to some of the practical aspects of the question of limits and tolerances, as customarily applied to the manufacture of

[1] General Electric Company.

For presentation at the Spring Meeting, Cincinnati, Ohio, May 21 to 24, 1917, of The American Society of Mechanical Engineers. The paper is here printed in abstract form and advance copies of the paper may be obtained by members gratis upon application. All papers are subject to revision.

munitions, rather than to attempt to establish standards of high technical value in assigning definite limits to the several classes of dimensions involved.

Most mechanical men who have had recent experience with munitions manufacture will agree with the statement that their troubles have not to any great extent been due to inherent difficulties with the tolerances in general; but have principally been caused by such factors as incomplete or inconsistent drawings and specifications, and lack of mechanical judgment on the part of inspectors in interpreting the drawings and specifications and in the use of limit gages. In fact, these aspects of the subject are of such major importance that it would seem that technical refinements may be postponed until standards of practice have been established with respect to these factors.

The average munitions drawing is fairly open to criticism and leaves much to be desired in the way of clearness and consistency. Such defects as the following are often encountered:

a Flat dimensions without any tolerances

b Dimensions with one tolerance only, either plus or minus

c Overlapping tolerances on two parts which assemble together

d The sum of the tolerances on intermediate dimensions are not in agreement with the tolerances on the overall dimension

e No limits are specified as to permissible eccentricity between concentric cylindrical surfaces, or between two parts which assemble together

f In the case of screw threads on two parts which assemble together, but where interchangeability is not required, no specifications are given as to the nature of the fit.

Defects *a* and *b* can be readily remedied by establishing an invariable rule that all dimensions must be the mean dimensions with equal plus and minus tolerances.

Defect *c* usually occurs in the tolerances for external and internal threads on two parts which assemble together, and is occasioned by losing sight of the fact that the maximum external thread must be slightly smaller in diameter than the minimum internal thread, in order that these extremes may assemble properly.

Defect *d* can best be avoided by establishing the invariable rule that all dimensions in the same direction must start from a common reference line.

Defect *e* is a fruitful source of trouble to the munitions maker, and consequently in all cases where close concentricity of cylindrical surfaces is essential, definite limits of eccentricity should be specified on the drawings.

Defect *f* can conveniently be illustrated by considering the fit of a nose-piece or base-plug external thread, in the internal thread in a shell. In this case the nose piece or base plug virtually becomes an integral part of the shell after it has been assembled. In fact, it is common practice to finish-machine or grind these parts after they have been assembled, and in subsequent operations such as loading keep them together by similar markings. Manifestly, all that is required from the standpoint of utility is that the nose piece or base plug should screw into the shell easily, but without too much looseness. As such threads are usually quite coarse, liberal tolerances are in order, but the dimensions and tolerances must be properly assigned in order to avoid the possibility of too much looseness. This can readily be accomplished by letting them overlap to some extent, which will of course result in producing some nose pieces and base plugs which will be too large to enter shells having minimum threads. This apparent difficulty is overcome by grading the nose pieces and base plugs, as, for instance, small, mean, and large. A mark can also be put on a shell at the time it is gaged which will indicate to the assembler which grade of nose piece and base plug to use.

RELATION OF TOLERANCES TO WEIGHT

Perhaps the most striking defect, in shell drawings particularly, is the discrepancy between the tolerance specified for the weight of the shell and the variations in weight of the shell from making one to maximum external and minimum internal dimensions, and another to minimum external and maximum internal dimensions. As a rule, shell drawings and specifications allow a variation in weight of plus and minus one per cent of the mean weight for the smaller sizes and less for the larger sizes, whereas the extreme dimension tolerances would permit two or three times as much variation in weight. Furthermore, no dependence can be placed on the assumption that a shell machined to the mean dimensions will have the mean weight specified on the drawing. Whether or not these discrepancies are intentional or accidental the writer is not informed, but it seems obvious that the drawings should be revised.

From the standpoint of ballistics uniformity in weight of shell is highly desirable, and consequently close weight tolerances are to be expected; but the drawings and specifications should sound a clear note of warning so as to prevent a manufacturer from proceeding on the assumption that the dimension tolerances can be used indiscriminately. Some tolerances bear evidence of having been added—probably to meet some difficulty in manufacture—without perhaps due consideration being given as to the extent to which the weight would be affected. In any event, it seems imperative that the drawings should be revised so that shells machined to the mean dimensions, and of steel of the specified quality, will have the mean weight.

If ballistic considerations permit, the weight tolerances should be increased, since they are at present the limiting factor. The drawings plainly state that advantage cannot be taken of all the extreme tolerances on any one shell.

These considerations are not advanced as an argument against larger dimension tolerances than weight tolerances, since liberal dimension tolerances afford a maximum of munitions production; but rather to caution the manufacturer to consider carefully all possible combinations of the tolerances which will produce the greatest uniformity in weight of the finished product, and also to suggest to the ordnance engineer the desirability of plainly pointing the way to attain the desired results.

THREAD TOLERANCES

Perhaps the most difficult operation in munitions manufacture is the cutting of internal and external threads within close limits. The Whitworth form of thread is particularly difficult to cut and has been the cause of endless trouble in recent munitions work. We all regard the rounding of t[he] top and bottom of this thread as particularly iniquitou[s] we are apt to regard the United States form of threa[d] greatly superior. As a matter of experience, it is quite d[iffi]cult to maintain the size of the United States form of threa[d] within close limits. The requirement that this form of thread shall fit on the top and bottom, as well as on the all-important angle, is the chief source of trouble. The very existence of this requirement results in most of the fitting occurring at the

top and bottom of the thread, rather than on the angle. It is practically impossible to avoid this condition since the tops of the threads on a tap wear away very quickly and therefore the tap does not continue to cut internal threads of full depth. As the thread gages are made of standard form, it is obvious that much of the work will not pass the gages, although perfectly correct as to angle diameter and pitch. To a less degree is the same condition true of dies and external threads. This defect is universally recognized in American machine shops and is quite commonly overcome by making the diameter of taps slightly larger than standard, so that they will cut an internal thread deeper than standard and also cut a larger hole or core than standard. This affords a clearance at the top and bottom for the external thread. It seems manifest that this necessary and customary practice should receive official sanction in the drawings and specifications for munitions, and that limits for these clearances should be specified.

INDIVIDUAL JUDGMENT OF INSPECTORS

Next in importance as affecting the manufacture of munitions is the question of mechanical judgment in interpreting the drawings and specifications on the part of the inspectors, and also in regard to the proper use of limit gages. Although many inspectors are men of excellent mechanical judgment and experience, a large number of necessity have not these qualifications. In fact, it would be detrimental to other lines of manufacture to require that only experienced mechanics be selected as munitions inspectors. It therefore seems that the obvious solution of this difficulty is to make the drawings and specifications so clear and comprehensive that men with little mechanical experience can become efficient inspectors. The specifications should clearly specify such details as kind and quality of finish for all surfaces, whether by turning or grinding, and if by turning whether the tool marks must be removed by filing. Some surfaces can, in the interest of maximum production, be left semi-finish-turned, and the specifications should in such cases so state. In general, this plan can be made most effective by basing the requirement of the specifications on actual results obtainable with modern machine tools, and all unnecessary refinements should be eliminated.

Regarding the proper use of limit gages, it is perhaps difficult to lay down general rules, but certainly such a fundamental one as that gages should never be forced can be advanced without hesitation.

MACHINE-TOOL LIMITATIONS

The limits of accuracy attainable on machine tools must be taken into consideration in determining how limit gages should be used. The screw thread affords a good illustration of this point. In a part where a threaded hole goes entirely through the part, it is not very difficult to cut threads of uniform diameter in the sense that the thread is uniform throughout its length and that it does not taper. In bottom-tapping a shallow hole, however, or in cutting a short external thread, both are apt to taper slightly, or at least the first thread or two will be thin. In the first case it is perfectly proper to require that the maximum thread gage shall not enter at all; but the second case manifestly demands different treatment. A rational rule would be to allow the minimum thread gage to screw in one-third or one-half the depth of a shallow not-through hole, and the same allowance should be made in the case of a short external thread. This proposition should be judged from the standpoint of utility rather than ideality, particularly when one stops to consider that the mechanic can, by cutting the external thread in the proper direction, make these inaccuracies actually balance each other.

To sum up, maximum production, which is the principal aim of any revisions, can be most readily attained by increasing the weight tolerances in the case of shells particularly. If, however, the ordnance engineer cannot allow any greater variations in the weight of shells, then, at least, the alignment of mean weight with mean dimensions, as outlined in the foregoing comments, will, it is believed, prove to be an important step in the right direction. As regards other munitions, where weight variation is not so important, much can be accomplished by aligning the dimension tolerances with the capacity for accuracy possessed by modern high-speed machine tools.

GAGES AND SMALL TOOLS

By FRANK O. WELLS, GREENFIELD, MASS.

Member of the Society

Of first importance in the manufacture of rifles, guns and munitions of war are gages. There are many types of gages, but the one used in the manufacture of munitions is the dimension or limit gage. Whatever instrument is used must be able to measure accurately and rapidly, and must also be durable, as very slight wear will destroy the accuracy.

It has been well said that if we can measure an article we can make it. The difficulty lies not in the making, but in the measuring; and our greatest obstacle in exact measurement is the human element.

In olden times the human element was the controlling factor in all operations. Work was done in very small quantities and was not interchangeable. Some work was good and some was poor, all depending on the man who did it. To meet the demand of the present day, we must have progressive manufacturing, where each man has only a small part of the work, and that part must be done by an ordinary workman. All this calls for a method of measurement different from that formerly used. Then we wanted one piece, now we want thousands of pieces, all alike and each one an exact duplicate of the other. This is easily accomplished by our printed instructions and gages, and with these we can start a large number of factories making war materials that will be one hundred per cent good, and also standardize the cost of production.

Improperly designed gages cause poor work and a lack of interchangeability, making the cost of production and the cost of assembling greater. Our Government should take advantage of the knowledge of this fact, obtained at such great cost in the present war, and should standardize all its operations, gages, and measuring tools, so as to avoid a repetition of mistakes of this kind.

The Government should have, first of all, its blueprints prepared indicating the proper tolerances perfected by tests and careful practice. The sequence of operations and the time taken to do the work should also be perfected and put in printed form with the necessary illustrations showing the set-up, as well as the best way to handle the work, both in the operation and gaging. This would enable all factories to standardize their productions.

The importance of the best methods of measuring is illustrated in a report from the U. S. Ordnance Department, in

For presentation at the Spring Meeting, Cincinnati, Ohio, May 21 to 24, 1917, of The American Society of Mechanical Engineers. The paper is here printed in abstract form, and advance copies of the complete paper may be obtained by members gratis upon application. All papers are subject to revision.

which the statement is made that the cost of inspection is from 10 to 12 per cent of the total cost of manufacturing. These are startling figures, and indicate that the proper gaging methods had not been used.

The output of the U. S. Government arsenals for the year 1915 was $11,284,113.95; for the year 1916, $9,471,300. It has been estimated on good authority that this could have been increased at least 50 per cent without increasing the size of the plants, by having a larger supply of gages and tools. The cost of such tools and gages is estimated at 20 per cent of the total cost of the plant, which shows conclusively the need of gages and small tools.

Few people realize that our Springfield rifle has more than one hundred parts and requires 1400 distinct factory operations. To produce 1,000,000 rifles requires $360,000 worth of gages for the original equipment, while renewals cost $400,000, making a total of $760,000. Each 1000 rifles made require 4800 gages. The renewal of the gages costs about 50 cents per gun. To make 10,000,000 rifles in 200 days requires at least sixty more arsenals than we now have. The war material most talked about is ammunition, of which our Government uses about 17 sizes at present. The cost, including the upkeep of gages, used in the making of 1000 rounds of ammunition per day, with a steady production for 200 days, is at least $2,225,000. These figures have been carefully worked out by makers well versed in the manufacture of gages for ammunition. It has been estimated by good authority that we should be able to make at least 200,000 rounds per day. The vast importance of the whole gage question can be realized.

Of course, some sizes of ammunition have to be made in much larger quantities than others. Careful estimates show the special jigs and fixtures would cost nearly double what the gages would. So far, the paper has only touched on ammunitions and rifles. To have everything on hand necessary, the figures given have to be multiplied many times.

There are today some 3,500,000 people in Great Britain engaged in making munitions of war in over 4500 factories. In doing this work to advantage, each workman should at least have $25 worth of gages, tools and fixtures.

The majority of contracts taken for ammunition in this country were taken by manufacturing organizations without experience on war material, and the gages first designed were not the best possible to insure economical assembling of the parts, with the result that a great many rejections were inevitable during the first months after production was attempted.

Our Government should provide itself with all the gages, tools, jigs, and fixtures far in advance of any possible expectation of requirement; the cost is small compared with the results obtained. This is a very simple business proposition — what every efficient manufacturing company would do.

It is a very poor policy to cut down on the number of gages and small tools. It is far better to use every labor-saving device possible. All this means a saving in high-priced labor, and this is very important in time of need when we cannot get the necessary skilled labor.

It is considered the best practice in manufacturing to put the thought and money not so much in the large machinery as in the small tools. The most important of all are the gages, and these must be so designed as not to have any guesswork about it. We must know that every part is machined right. We must be able to say, "We know this is right," and not say, "I guess we are right."

To most people gages seem of small importance, but as this paper endeavors to show, they are quite the reverse.

IMPORTANCE OF INTELLIGENT INSPECTION IN MUNITIONS MANUFACTURE

By E. T. WALSH, NEW YORK, N. Y.

Member of the Society

A STRIKING example of the difficulties that may arise in inspection work has been afforded during the present war in one contract for the manufacture of 5,000,000 rounds of ammunition which was completed by the contractor subletting the work among more than one hundred manufacturing plants in the United States and Canada, the time and the magnitude of the work making this necessary. The contractor, for his own protection, had to inspect all the product as it was made by the sub-contractors, and a corps of inspectors was required in each plant, the number of such corps being equal to the number of plants doing work. Great difficulty was experienced in getting men qualified to do this work, because there were practically none in this country who had experience in the manufacture of munitions, and but few available who had any kind of inspection experience.

To expedite the delivery of the finished product, the Russian Government placed its inspectors in the plants of the sub-contractors where they received the finished parts directly from the contractors' inspectors. Russia was as little prepared to provide the required number of qualified inspectors as was the contractor, and in consequence the manufacturer had inflicted upon him so-called inspectors selected from every walk in life, it seemed, except the mechanical, and barbers, bartenders, butchers, students and teachers were the usual thing and the practical man the exception.

The specifications for the ammunition were so drawn as to leave a great deal to be interpreted by the inspector, who was rarely qualified to intelligently pass upon the point at issue. The following extracts, copied from the specifications, will serve as examples:

> "There shall be no scratches, slivers or cuts on these parts."
>
> "If, independently of the above, in order to ascertain the qualities . . . the Receiver shall deem it necessary to make . . . other experiments, the factory shall give him all necessary means for making such tests."
>
> "For the measuring and verification of the projectiles the factory is under obligation to furnish a sufficiently vast, light, dry and warm room and place at full disposition of the Receiver, as well as furnish cupboards for the keeping of verifying instruments, scales of sufficient sensitiveness, electric lights of sufficient energy, for the examination of projectiles and gross power."
>
> "For the measuring of the projectiles, the factory shall furnish the Receiver, for his exclusive use all verifying working instruments . . . prepared according to the instructions, *as well as according to the indications of the Artillery Receiver.*"
>
> " . . . the finish of these surfaces must be brought to such a degree as is obtainable when working with a tool."

The slightest scratch or tool mark was soon magnified into a cause for rejection. One sub-contractor claimed that he was required to unbox several thousand shrapnel because the Rus-

For presentation at the Spring Meeting, Cincinnati, Ohio, May 21 to 24, 1917, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. Pamphlet copies of this paper may be obtained by members gratis upon application. All papers are subject to revision.

[illegible] a flyspeck on the copper band of one of [illegible]. In spite of the fact that gages were called for by the [illegible] for certain [illegible] points, the inspectors were not satisfied with them, but asked to be furnished with others of a design that would be more searching and exacting. Under the [illegible] covering the finish of the shell, the inspectors were soon demanding a finish that could only be obtained by buffing, and the unfortunate part was that the manufacturers had no redress, because there were no standards of finish established, there was no set of standard gages, nor was there any superior authority to whom the contractor could appeal and whose decision was final.

From [illegible] experience of two years' struggle to produce work under such conditions, the writer is constrained to appeal for coöperation in the endeavor to standardize and systematize the production of munitions, so that manufacturers will in future have definite instructions and standards to work to and, in the case of honest differences of opinions, a Bureau of Appeal, where questions will be decided definitely and authoritatively.

Drawings should be checked and re-checked until the possibility of error has been reduced to a minimum. Tolerances should be decided upon that will allow the greatest leeway compatible with good work.

Every effort should be made to make the specifications simple, clear, explicit and absolute. They should leave nothing open to the discretion of the inspectors. The specifications should describe the gages to be used and how to use them.

The gages used should be as few as will check up the product in all of the important features. What these gaging points and their limits should be, should be determined by competent military engineers, working with the idea of getting a product that will meet all requirements and still be practicable, so that the quality produced will not be curtailed by unnecessary refinements. Exactness should be required where it is necessary, and where it is not necessary there should be no holding down to ridiculously close limits.

Corps of inspectors should be enlisted from our numerous manufacturing plants and thoroughly drilled in the use of gages and the meaning and intent of the specifications, with particular stress laid upon the fact that inspection should be made with the idea of accepting as many as possible, rather than a high count of rejections.

Each manufacturer should be supplied with a set of correct sample gages, with their masters and grand master, by which the working gages should be made and checked.

An approved sample of the product to be made should be furnished to each factory, to be used for comparing the same with the regular product when necessary. These samples should be official, and product equal to sample should be accepted without question.

It is most important to have a bureau composed of qualified engineers to interpret specifications and render final decisions on all points that may arise. Manufacturers should have the right of appeal to this board and its unbiased opinion. At this bureau should be kept on view officially accepted samples of all parts in the various stages of manufacture, to be referred to when making decisions.

The Académie des Sciences, according to the *Génie Civil*, has resolved to establish a national physical and mechanical laboratory for the purpose of scientific research directed toward industrial uses. The laboratory will be controlled by a council, of which half the members will be nominated by the Academy, one-fourth by the State Department, and the remainder by the chief industrial associations. The executive control will be in the hands of a small technical committee. Existing laboratories engaged in similar work will be affiliated to the National Laboratory, and will work in close relationship to the latter. Substantial funds will have to be provided for the working expenses of the laboratory and for the assistance of the affiliated institutions.

Stellite vs. High-Speed Steel. According to an account given in *Métaux et Alliages,* the hard non-ferrous alloy, stellite, invented three or four years ago in the United States by Elwood Haynes, marks a still greater advance in the art of cutting metals than established by the notable results obtained with the introduction of high-speed steel some years earlier. Where rate of production is a critical matter, as in the manufacture of ammunition, it has already made a remarkable record in competition with high-speed steel, a material which in point of capacity of production outclassed steels previously used. One of the advantages of stellite is that its hardness, which it maintains even at a red heat, is solely dependent upon the composition of the alloy, tungsten and chromium with additions of cobalt and molybdenum, and not upon the difficult and uncertain operations of heat treatment. Its fundamental advantage, however, lies in its ability to withstand a marked increase in speeds and feeds over those previously used with high-speed steels.

Among the already numerous machine shops employing stellite, the Fonderie des Gobelins in Paris reports that a daily production with high-speed steel of 120 shells of 155 mm. was increased to 200 by the use of stellite. With high-speed steel 21 minutes were consumed in roughing out at a speed of 17 meters and a feed of 0.7 mm. For finishing, the same speed and feed were employed and the same time was consumed. With stellite the roughing-out occupied 11 minutes at a speed of 25 meters and a feed of 0.85 mm. For finishing a speed of 37 meters was maintained with a feed of 1.67 mm. consuming 4 minutes. For completely finishing 1,000 shells of 155 mm., the cost of stellite is about 0.30 francs per shell. Other firms report equally favorable results in this class of work.

MACHINE SHOP PAPERS

SPECIAL emphasis has been placed on the Machine Shop Session of the Spring Meeting for the reasons that Cincinnati is the machine-tool center of the country and that the National Machine Tool Builders' Association will be in convention at Cincinnati at the time of the opening of our own meeting. Three papers are to be presented and discussed at this session, which is under the auspices of the Society's Sub-Committee on Machine-Shop Practice.

A FOUNDATION FOR MACHINE-TOOL DESIGN AND CONSTRUCTION

By A. L. DE LEEUW, PLAINFIELD, N. J.

Member of the Society

THE rapidity of progress of the various branches of engineering may be said to be in proportion to the ease with which their principles can be reduced to mathematics. This was never so clearly shown as in the case of the development of alternating-current apparatus. It may almost be said that the branch of alternating-current engineering was, like Pallas Athene, born full-grown. Here was a case where the science, the mathematics of this branch, was at hand, waiting for somebody to apply them. As a result, alternating-current apparatus has known no period of experimentation, of stumbling, fumbling progress.

Compare this with the slow, hesitating development of the steam engine in its first stages. In that case nothing was known except that steam would exert pressure; but no knowledge existed of the properties of steam, of thermodynamics, nor of the mathematics of engineering materials. The moment that the fundamental facts of thermodynamics were understood and were reduced to mathematics, the progress of the steam engine became more rapid.

It then became possible to imagine an ideal steam engine, which is another term for a 100-per-cent-efficient steam engine, and to show what is the maximum obtainable efficiency in any steam engine. It was therefore possible to express the efficiency of existing or of contemplated steam engines in percentage of the ideal engine. In other words, the ideal steam engine became the standard or unit of measurement. It was no longer possible for any designer or builder to think that he had produced a steam engine of the highest possible efficiency, merely because his steam engine was twice as efficient as some other existing engine.

SCIENTIFIC DEVELOPMENT OF MACHINE TOOLS

What are the things we should know about tools and machine tools to enable us to make these important servants of our present-day civilization follow the line of development which the steam engine has enjoyed?

Is it possible to develop a theory of the ideal machine tool, such as has been developed for the steam engine?

Fig. 1 shows two stress diagrams of cold-rolled steel, of which one specimen had a tensile strength of 95,000 lb. and an elongation in 4 in. of 12 per cent, and the other a tensile strength of 85,900 lb. and an elongation in 4 in. of 7.4 per cent. The area of both pieces was ½ sq. in. and the length between gripping jaws 2 in. The amount of work done in separating the first piece was 3500 ft-lb. per sq. in. of section, and for the second piece 2000 ft-lb. per sq. in.

In parting the pieces, the same result was obtained as if half the piece were removed by means of a cutting tool. Of course, this way of removing metal does not permit of controlling the shape or the finish of the remaining piece; but just the same, a certain amount of metal has been removed as effectively as if it had been done with a cutting tool. If this amount of metal had been removed by a cutting tool used in one of the present-day machine tools, the amount of power required to do this work would have depended on the quality of the tool and the nature of the machine; but in no case would it have been less than ½ hp., assuming a reasonable time element.

If the only function of a machine tool were the removal of metal, we would find that our best machine tool has an efficiency

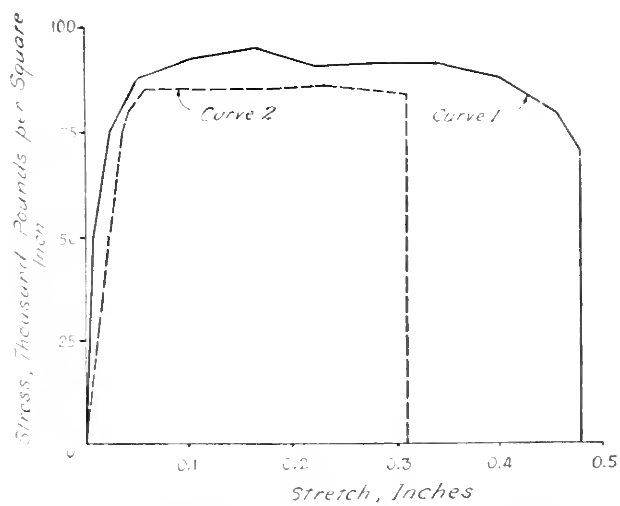

Fig. 1 Stress Diagrams of Cold-Rolled Steel

of from 0.12 to 0.22. Even the better of these figures is very low compared with the efficiency of other machines.

If chips could be removed from a piece of work by a straight pull, the ideal machine tool would be one which would remove material with the same amount of power expenditure as that required by the testing machine. While we would not expect to obtain such efficiency in practice, we would certainly aim to reach a much higher efficiency than we are able to obtain now. However, the question is whether material *is* removed by a straight pull, and this leads to the confession that the writer does not know what the exact nature of the cutting of metal is, and he believes further that he is not alone in his ignorance.

To the writer's knowledge, no experiments have been made which establish the true nature of the cutting of metals with a reasonable certainty. In The Art of Cutting Metals and elsewhere diagrams are shown of the supposed action of a cutting tool. (See Fig. 2.) The writer believes that these diagrams represent a very good first guess; but he wishes to point out that this guess is not based on anything better than the inward vision of the authors of these various works. If this guess is

For presentation at the Spring Meeting, Cincinnati, Ohio, May 21 to 24, 1917, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. The paper is here printed in abstract form and advance copies of the paper may be obtained by members gratis upon application. All papers are subject to revision.

correct, then the act of cutting metal is a removal of the chip by tension, and the amount of power consumed for cutting should not be more than that required by the testing machine. If this is so, the total wastage of power in all the machine shops of the world is enormous, and it certainly would be worth while to investigate this matter thoroughly, merely from the standpoint of the conservation of energy.

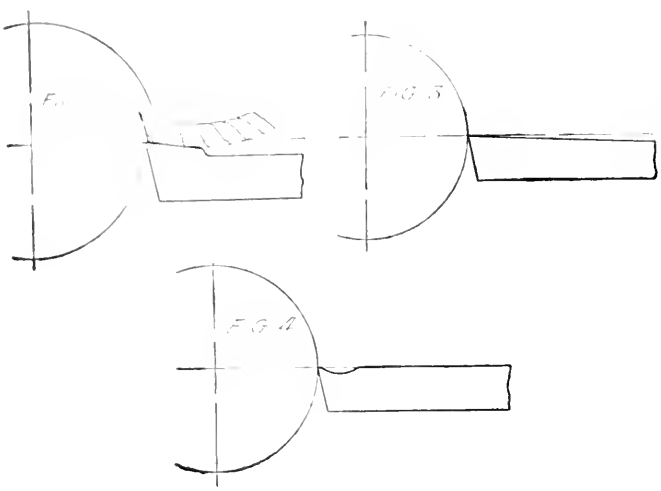
QUESTIONS WHICH NEED TO BE ANSWERED

Among the questions which should be answered before we can design machine tools in a thoroughly scientific manner are the following:

1 When we turn up a narrow disk by means of a square-nosed turning tool of which the width is greater than the width of the disk, is the action of removing the chip purely a matter of tension; or, if not, what is it?

2 Does the front end of the tool have any function at all?

3 How far from the edge of the tool is the point where the chip strikes the tool?



FIGS. 2, 3 AND 4 CUTTING WITH LATHE TOOLS

4 If the action is purely a matter of pull, and the chip does not strike the top of the tool at the cutting point, but some distance farther back, then is it necessary that the cutting edge of the tool be sharp?

5 What is the nature of the lamination of the chip?

6 How much power is required for the actual removal of the chip, for the friction between chip and tool, and how much for laminating the chip?

7 What would be the best shape for such a turning tool for this particular turning operation?

8 How does the amount of power vary with the various angles of the tool?

9 If the turning operation is not as simple as the one assumed in Question 1; if, for instance, there is a side feed, such as in ordinary shaft-turning operations, how is the cutting action modified by this side feed?

10 If the chip is removed by the action of the top of the tool, that is, if the front of the tool has no function, then what determines the nature of the finish of a cut.

11 In what relation does the power required for the side feed stand to the power required for the actual removal of the chip.

A great many other questions which could be asked cannot be answered at the present time, and still more questions would naturally present themselves as soon as we had some little elementary knowledge on this subject.

ACTION OF A CUTTING LUBRICANT

As dark a subject as the action of the tool itself is the action of a cutting lubricant. It is a well-known fact that the use of a lubricant and the nature of the lubricant used affect both the finish and the size. A very pertinent question which might be asked, is this: If the chip is laminated by tension, that is, if the point where the chip begins to separate from the work is some distance ahead of the point of the cutting tool, how can the cutting lubricant affect either size or nature of finish?

Another equally puzzling question is: If one of the functions of the cutting lubricant is to reduce the friction between chip and tool, why should we not use a heavy lubricating oil instead of a light lard oil, which has practically no lubricating qualities?

Or again, we might ask this question: If, as facts seem to show, the best results are obtained with a cutting lubricant which has little viscosity and which therefore, can readily rise between chip and work by capillary action, what is the action of the oil on the separation of the chip, seeing that the oil only gets to the point after the chip is separated?

Even more puzzling than the effect of a cutting lubricant on finish is the effect it seems to have on the size of the work. We do not see at the present time how it is possible for the lubricant to influence the size, yet that it does do this has been observed a great many times.

The writer had occasion to look into this matter when trying to determine the best cutting lubricant for automatic screw machines on small and medium-sized work. The lubricant in use was a mineral oil with 15 per cent lard oil. A certain job was selected, for which a form tool was used, and 24 screws were made with the regular compound. The screws came true to size within the limit of one-half of one thousandth. The oil was then removed from the machine and machine and tools were cleaned. The cutting compound to be investigated was substituted and another 24 screws were made. These screws were all larger than those cut with the regular oil. Furthermore, they varied from two and one-half to five thousandths over size. The machine was once more cleaned, and the original oil put back. The screws again came uniform and to size, showing that the cutting of the first 24 screws had not dulled the tool or caused any other disturbing element to enter into the equation.

The fact that the cutting compound caused the screws to be over size might possibly be explained by a difference in heating or cooling effect of the different lubricants; but how can the difference in size of screws made with the same lubricant be explained, when there was no such difference with the use of the oil?

Many other questions could be asked which can not be answered at the present time. This should not prevent us from carefully investigating the true action of cutting metals, and determining the fundamental data, if we are interested in this matter in a purely scientific way. However, the engineer should not indulge in scientific investigation, unless he feels that the results will be of practical value.

To be of value, the results should lie in the direction of saving of power, diminished wastage of tools, and less strain on the machine; or in the direction of increased output, with

or without the other advantages. That such advantages may be reached seems very clear to the author, and he wishes to outline some isolated experiments which, though not complete in themselves, point to very interesting possibilities.

Forged spindles of sixty-point carbon steel were roughed by a tool as shown in Fig. 3. As a rule, the tool was able to rough three spindles before a breakdown. In its broken-down condition the tool appeared as shown in Fig. 4. A hollow had been ground out by the chip, but a land of a little more than 1/64 in. in width had been left at the front end, showing that the extreme front of the tool had not been in action. The experiment consisted of carefully measuring the broken-down tools and making new tools of just that shape: in other words, a tool like the old tool, but with a hollow ground in the top of the same shape, size, and location as in the old tool.

This tool is shown in diagram in Fig. 4. The hollow was carefully polished, and a tool thus prepared would rough from 9 to 13 spindles. Examination showed that the hollow in the tool would remain smooth almost to the last, and that a complete breakdown followed very soon after the surface of the hollow began to show scratches. No tests of power consumption were made, but it may be expected that the power required with the old tool was more than with the new tool, as the chip did not have to bend so sharply and as the work required for hollowing out the tool was omitted.

Another interesting point about this tool was that the actual contained angle between the front of the tool and the front of the hollow was much less than we would have dared to make between the front and top of an ordinary lathe tool, especially if this lathe tool were to be used for roughing. Nevertheless, under the conditions given, this tool, with the small front angle, stood up better than the original tool with the large angle.

In The Art of Cutting Metals, Mr. Taylor stated that his experiments showed no perceptible difference in power consumption for various contained angles of the cutting tool. The writer thought that this conclusion would probably be correct only for the range of cutting angles tried by Mr. Taylor. He imagined that the relation between contained angle and power consumption would probably be a curve of the nature of Fig. 5, and that all the experiments made by Mr. Taylor were within the horizontal part of the curve.

The writer, therefore, set out to experiment with angles much below the angles mentioned in The Art of Cutting Metals. Realizing that an ordinary lathe tool would not stand up with much smaller angles than those used in present-day practice, he devised the tool shown in Fig. 6. This tool is a body of revolution, and was held in a rigid block of metal and directly over the lathe carriage. Fig. 7 shows the arrangement of tool and tool holder used. The tool was used for turning, preparatory to grinding, milling machine overarms, about $4\frac{1}{2}$ in. in diameter and 5 ft. long. When the tool gave out, it was turned in the tool holder so as to present a new piece of the edge to the work. In this manner, from 12 to 16 settings could be made with one sharpening of the tool. The sharpening itself was a matter of circular grinding. The tool would make a very smooth cut, and without a steady rest would turn half the length of the bar with a variation in diameter of less than three thousandths. The surface of the work was unusually smooth, and the amount required for grinding was much less than usual. Unfortunately, the lathe on which this work was done was too large and heavy to make accurate power readings for so slight an amount of power consumed, the cut being only 3/16 in. reduction in diameter, and with a feed of 1/16 to 3/32 in. The action of the tool was quite peculiar, and did not give one the impression that metal was being cut. Though nothing was learned about the relative efficiency of this tool, the writer thinks it worth while to bring it to the attention of the Society, on account of the possibilities for further investigation to which it points.

This matter of the relation of the contained angle to the power consumption for a given cut had previously led to the introduction of the helical cutter, where the actual angle of the tool is not small, but where the tool is presented to the work in such a manner as to have the effect of a small angle.

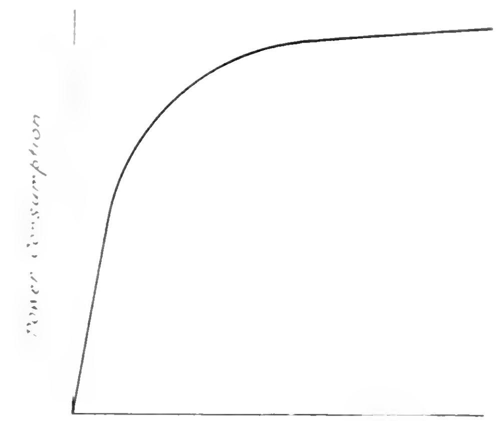


Fig. 5 Probable Relation Between Contained Angle of Cutting Tool and Power

Another experiment, more or less related to the same question, was an attempt to use a rotary lathe tool, such as shown in Fig. 8. The edge of this tool would bear up against the work Fig. 9, so as to have a very slight difference in speed between the work and the tool, and it was further set in such a way as to make the virtual cutting angle very small. The result was that it became possible to use very high cutting speeds without any apparent effect on the tool. The cutting speed was limited by the machine only. With work [illegible] in. in diameter and a feed of 12 [illegible] of 650 ft. was used for cast iron as well as [illegible] cutting was done dry. Again no attempt [illegible] accurate data as to power consumption [illegible] realized that the lathe in its present form [illegible] adapted to this kind of cutting tool. The chips made by this tool were not broken up, and were practically solid steel bars. Furthermore, the chips as they came off the lathe were cold enough to be caught in the hand. It is therefore very likely that a test would have shown a remarkably low power consumption.

Though the foregoing experiments are incomplete in them-

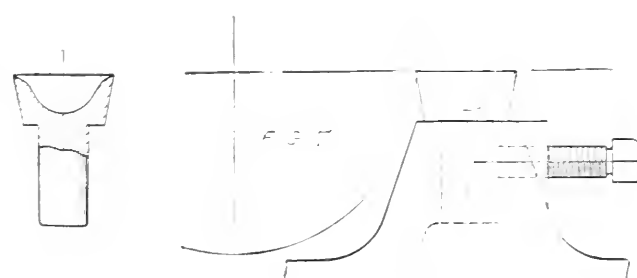

Fig. 6

Figs. 6 and 7 Author's Small-Angle Tool and Tool Holder

[illegible] they do show that there are great possibilities before us, and, further, that these possibilities lie away from the present-day shop practice. The writer believes that it would be almost useless to try experiments along a great many lines, and by a great many experimenters, without a complete plan of campaign, and that such a plan of campaign should be based on some theory, or at least on some hypothesis; and he further believes that no such hypothesis can be developed unless we start in collecting some elementary data.

A few years ago, Mr. L. P. Alford, who was then in close touch with the writer on this subject, approached Dr. Stratton of the Bureau of Standards, with the view of having that bureau take up the first investigation of the process of cutting metal. Dr. Stratton promised the assistance of the bureau, and at a preliminary meeting a general plan of campaign was discussed. The writer believes that an order was placed for a special dynamometer for measuring the stresses in various directions when planing metal. This proceeding will probably give some valuable data, but, according to his ideas, not

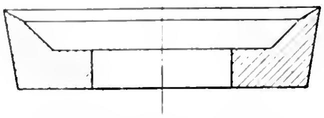

FIG. 8 EXPERIMENTAL ROTARY LATHE TOOL

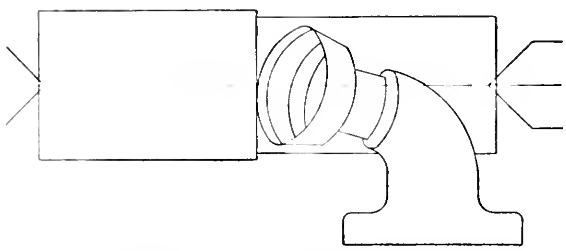

FIG. 9 ROTARY TOOL MACHINING SHOULDER

of a kind which will make it possible for other experimenters to use them as a basis for their own experiments.

SUGGESTED LINES OF EXPERIMENTATION

The writer believes that interesting results may be obtained by following a line of experimentation such as the following:

An instrument should be built, somewhat along the lines of a microtome, in which a soft material is to be cut by a razor-like blade or tool. This tool should be arranged so that it can present various angles to the work, and tools of various contained angles should be experimented with. The angles presented to the work should vary as to angle of clearance, angle of rake, and angle of shear. A dynamometer, which should be part of the instrument, should register the pull required for the cut. The material to be cut should be standardized, and it is suggested that paraffin may fill all requirements; by selecting a paraffin of standard melting point, we would also get a material of standard hardness. In this manner the relation between cutting angles and power required could be established over a very wide part of the curve. Though the actual figures obtained would not be immediately applicable to metal cutting, it would make it possible to find the controlling law, and this done, it would then be possible to investigate the cutting of harder materials over a small portion of the curve, and compare this portion with the corresponding portion of the curve already obtained. The same instrument could possibly be used for tests on such materials as lead, soft white metal, etc.

Another line of experimentation would be to arrange some machine tool, such, for instance, as a lathe, for running at very low speed, say 1 in. per hour; mount a steel disk on this lathe, and take a cut at the circumference of this disk. In this manner the cutting action would be of the simplest kind, as the tool to be used could be a square-nosed tool of greater width than the thickness of the disk, so that there would be no side cut. A moving picture taken at a high rate of speed could then be reeled off at a low speed, and it would probably be possible in this way to visualize what actually takes place in cutting metal. It would readily show whether cutting is merely the result of tension, or whether shear plays a rôle, or whether both are responsible. It would probably show whether the chip leaves the work ahead of the tool point, and whether or not the front end of the tool is in contact with the work. It would probably show many other things besides, and might be made the foundation for a number of lines of experimentation.

The writer believes that the time has come to try to interest as many engineers as possible in the subject of collecting fundamental data in regard to the cutting of metals, but rather than to suggest individually some method by which universities, industrial establishments, and engineers might be asked to coöperate, he prefers that this matter should be discussed by the Society, and would like to have this paper lead ultimately to a systematic effort in this direction, fathered by The American Society of Mechanical Engineers.

MACHINE-SHOP ORGANIZATION

BY FRED G. KENT,[1] CINCINNATI, OHIO

IN this paper it is my purpose to outline briefly the basic structure of an organization for a shop building the average line of machinery. I shall not touch at all on the commercial side of the organization, such as sales, advertising, financial, and purchasing, but will confine the paper entirely to the manufacturing end.

As all my experience has been with concerns in operation for some years before my becoming connected with them, I have always had the advantage of having considerable high-grade material, both in the way of men and equipment, ready at hand to work upon, which accounts for some of the ideas expressed below.

While I have been associated with some very large concerns, I would rather these remarks apply to the shop employing 600 men or less, for a shop of this size, from the very nature of its growth and the volume of business transacted, has just as many, if not more, obstacles to overcome as the larger plant, and is usually in no condition financially to set aside any large sum for betterment work. For this reason it is necessary in a business of this sort to plan any forward move with the greatest care, in order that there may be sure profit in each change made, and all such changes may take place at such times as to cause no interference with getting out the regular product.

This, of course, means rather slow progress, which is apt

[1] Lodge and Shipley Machine Tool Co.

to be discouraging to the man who is anxious to see things go, but, on the other hand, it has a decided advantage in the fact that the evolution is so gradual that there is very little opposition or unfavorable comment from foremen or workmen inclined to discredit innovations. This in itself is a very important factor toward any reorganization scheme, for, notwithstanding arguments to the contrary, the stability of any shop system depends very largely on whole-hearted coöperation, from the chief executive clear down the line to the sweeper.

Some time ago James Collins made the statement in a magazine article that "during the next few years some of the largest profits in American industry will be saved out of operation. Heretofore our profits have been made, but saving a profit is a different thing altogether." I quite agree with this, and my work for several years has proven to me that hundreds of small details are allowed to take the wrong course simply because they have always gone that way. We have all of us been too much concerned in systems of paying wages, with the object, of course, of getting more work at a lower cost. Sometimes straight piece work has been adopted, and again it might be some one of the several forms of the bonus or premium plan, and in nearly every one the feverish desire to get something started has precipitated action without proper planning, and has brought about useless waste of time and energy, and, in many cases, ill-feeling among the workmen. If for no other reason than that of harmony, let us leave the time-study and wage-payment schemes until we feel sure that we have very nearly gone the limit in stopping other leaks.

My first point is that wage payment, premium schemes, bonus arrangements, etc., should be the last point of attack rather than the first.

Let us suppose that we are going about the reorganization of such a shop as I have mentioned. What is the best course to take? It is my opinion that the easiest way out, and at the same time the one most profitable, is for the directors to place a man of proven executive ability at the head of a military or line type of organization, giving this man plenty of time and a free hand to work out the solution of their problems. This arrangement will prove successful more times than any other.

The selection of a title for the man who is to lead the way is a matter of considerable importance, and, if possible, the position should be a newly created one. For instance, if the chief executive has been known in the past as a supervisor or general superintendent, let the new position be that of Works Manager. Such an arrangement enables the old superintendent to retain his prestige with the men until it may be deemed proper to make a change, and it also starts the new man off with more of a punch.

The question is often asked, "Where can we get the right sort of man?"—and the answer is that he is not half so hard to find as is generally thought. Many a time the man is already in the organization, but he has been so thoroughly "hog-tied" that he has never had a chance to show what was in him.

Assuming that the right man is on hand ready to take hold, if he is a newcomer in the concern he should be given at least two months to get acquainted, first with the owners, carefully analyzing their statements of troubles. After two or three days on this end of the job, let him go out into the shop and get acquainted with the department heads, encouraging them to talk of their troubles, and if possible have them express an opinion as to the causes of failures in the past. Let him drop into the works in the evenings and cultivate even the watchman's acquaintance. He will find that long hours spent alone in the shop are frequently productive of leads of value. Let him walk through the machine and erecting departments on Saturday afternoon, and an occasional Sunday for a time, looking into every corner and cubby-hole. The number of points that can be brought out in a survey of this kind will surprise one who has never tried it. All this is a mere matter of getting acquainted with the job, and it goes without saying that if this point is neglected all future work will rest on an insecure foundation.

The location of the headquarters of the new works manager should be open to all shop employees and the men encouraged to come in. It should, therefore, be in the place most accessible to the works, and it should also be perfectly plain in its appointments. The business to be transacted with the shop can be carried on over common oak desks and bare floors with a far better feeling than it can over mahogany furniture and oriental rugs. The average workman does not care to come with his greasy shoes, soiled clothes and dirty face into an elegantly appointed office to talk about the things the manager ought to know about, and when he does, he is self-conscious and ill at ease, and goes away without half stating his case and irritated because of a feeling that he has been put at a disadvantage.

Now, when the works manager has learned to find his way around without a guide, and the men in the shop have learned to take his presence as a matter of course, let him start the first forward move by analyzing his shop conditions and personnel, and laying down a definite organization. Of course, any organization that he may plan in the start will be changed in minor details many times, but there is no reason why the main structure should not remain practically the same as originally planned.

It is understood, of course, that what one is seeking for in this move is to subdivide the entire plant into a number of different units, placing a definite responsibility upon the head of each unit, and it is understood that the heads of these units will be respected in the positions that they hold, or, in other words, there must be no splitting of authority or going over one's head with orders of any sort. For instance, the giving of orders directly to a workman by a general foreman or anyone else higher in authority is a serious breach of discipline, as it soon weakens the foreman's standing with the men to such an extent that he soon becomes useless as an executive. The same thing holds good, in a much greater degree, in the relationship of the owners to the head of their manufacturing operations. This may seem an insignificant point to bring out in a paper that is only touching the high spots, but I believe that many shops in need of reorganization owe 90 per cent of their troubles to the failure to fix definite responsibility and live up to it.

This subdivision of the shop is readily visualized by means of an organization chart which will give the layout of responsibility as well as the physical layout. In making up this organization chart, I have found that the easiest way is to use round metal-bound cardboard tags distributed on a large drawing board (see Fig. 1).

The first tags made out should contain the names of the main departments. The average typical shop should have the following departments: Works Office, Engineering Department, Pattern Shop, Tool Design and Storage, Tool Making and Repair, Plant Engineering and Power, Machinery, and Erection.

This division of the shop is merely typical, and it must be understood that all sorts of variations are necessary, due to the

varying factor of the personnel from which the organization has to be made. I might say here that I am a very strong believer in using the personal material at hand rather than replacing the old employee by new help.

The next step is to add to each department tag the name of the man who is selected to have charge of that department. With these tags spread out on the drawing board, with two more tags for the Works Manager and an Assistant Works Manager, and a number of smaller tags for the subdivisions of the major departments, the general shop organization begins to take shape.

I want to insert here that the Assistant Works Manager should be capable of assuming the work of the works manager in the latter's absence from the plant, and both the works

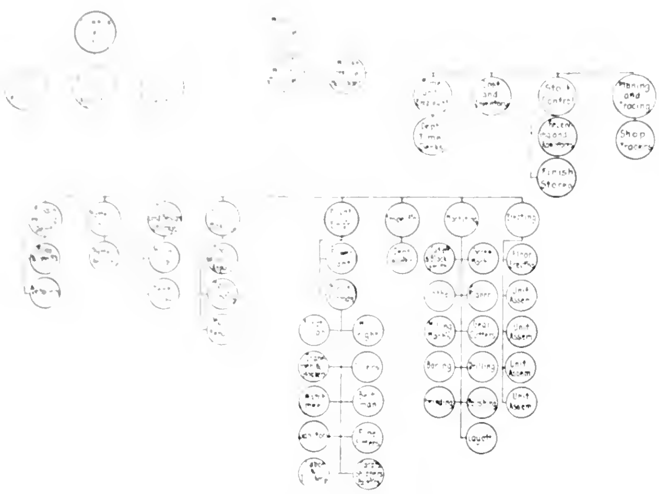

Fig. 1 Typical Organization of Shop with 300 to 500 Employees

manager and the assistant should have as few routine duties as possible. Their time should be spent in planning improvement and in bolstering up the weak points in the organization. A great many men get the idea that organization once done is done forever. On the contrary, the only organization that is final or complete is a dead one. I have cleaned up two plants after several firms of so-called efficiency engineers had had a shot at them. They had gone away after a time, leaving a mass of charts, forms and card indexes which were supposed to have accomplished a complete reorganization. Even if this reorganization was sufficient for the needs of these plants at the time they left, which it was not, it would be foolish to suppose that it would automatically administer affairs for an indefinite period. The business that is managed by live men is always subject to profitable changes.

The balance of this paper is covered by an analysis of the departments enumerated above, beginning with the Works Office, which the author considers the most important division of all, and concluding with the Erection Department.

The author states that the paper just touches the high places, but it outlines the basic structure of an organization for a medium-sized shop building the average line of machinery.

The chairman of the British Engineering Standards Committee, Sir John Wolfe Barry, has accepted the invitation of the Council of the Institution of Civil Engineers of Great Britain to give the James Forrest lecture on Wednesday, May 2.

METAL PLANERS AND METHODS OF PRODUCTION

By CHARLES MEIER,[1] CINCINNATI, OHIO

The problem of providing the increased speeds and power to develop the possibilities of high-speed steel and to meet the increasing necessity for greater production has been a comparatively simple one in such machines as lathes, drilling machines, boring mills, milling machines in which the cutting is continuous and the motion of the tool is in one direction only. In this type of machine it has meant merely adding power and strengthening parts.

The speeding-up process introduces, however, a vastly different problem in such machines as slotters, shapers and planers, in which the cutting is not continuous and which have a return motion of the tool. The principal limitations of machines of this class, especially the planer, are twofold, *first*, the inertia of the moving mass at the moment of reverse; *second*, the speed at which the tool enters the work. The problem of overcoming these limitations has had the attention of quite a number of engineers, and while considerable progress has been made the complete solution does not seem to have yet been reached.

The evolution of the planing machine has followed along the lines of increased table speeds. The earlier demands were all for a higher return speed, in the belief that great savings could be effected by reducing the idle time consumed in the return of the table.

It next followed that further gains could be made by increasing the cutting speed, owing to the fact that this part of the cycle consumes the greater part of the time involved. The advent of high-speed steel can be credited largely with the marked advance in this part of the development.

After fairly high speeds in both directions were obtained there came the demand for variable cutting speeds. It soon became a recognized fact that to operate a planer having only one cutting speed was both wasteful and detrimental to the best methods of increased production.

This constant change of conditions, and the desire to obtain the highest possible speeds in both directions, led to serious difficulties for which a change in design became imperative.

One of the objections to the speeding-up of the planer was the difficulty encountered at the reverse, namely, the inertia of the moving parts. Several tests were conducted which established the fact that the greater part of the trouble was caused by heavy machine pulleys and their high speeds.

Various types of magnetic, pneumatic and mechanically operated clutch drivers were designed in which the pulleys were not reversed. Our experience with these drives was that they developed the objectionable features inherent to friction clutches, namely, the slippage and wear which take place before the parts are properly engaged. The most successful of these types was the pneumatic clutch.

A few planers were built which embodied heavy springs to overcome the shock at reversing. We designed one machine in which these springs were added into the driving gears, and in another machine the table rack was made floating and held in place by two heavy springs at either end. These designs did not prove satisfactory, owing to the variable pressures while under heavy or light cutting. Also the springs had very little effect at the moment of reverse.

---

[1] The Cincinnati Planer Co.

For presentation at the Spring Meeting, Cincinnati, Ohio, May 21 to 24, 1917, of The American Society of Mechanical Engineers. The paper is here printed in abstract form and advance copies of the complete paper may be obtained by members gratis upon application. All papers are subject to revision.

It seemed that none of these arrangements quite met all conditions, and to overcome the difficulties in the standard belt-shifting machines experiments were conducted with lighter driving pulleys. A step which marked quite an advance in this direction was the use of an aluminum alloy for the pulleys instead of cast iron. It was found that not only did this overcome the greater part of the objections to the heavier pulleys, but that higher speeds were possible so that a decided gain was made in the number of cutting strokes owing to the fact that less time was consumed in the reverse. Table 1 gives results of a test made on a 30 x 30 x 14 ft. planer and gives a good idea of the gains effected by the use of aluminum pulleys.

These pulleys were also found to effect quite a saving in power. Table 2 shows a test made on a 76 x 62 x 32 ft. planer, in which the saving in power was about 25 per cent.

The subject of individual electric-motor drive for planers has received considerable attention in the past few years. One type of drive which has been successfully developed is the variable-speed drive. This consists of a 2 to 1 variable-speed motor coupled direct to the top driving shaft of the planer. The speed of this motor is controlled by two separate sets of resistances which are automatically operated by a master switch connected to the shifting mechanism of the planer.

The cutting speed can be varied from 25 to 60 ft. per min., while the return speed may be varied if desired without affecting the cut. The controller handles are set to a predetermined speed before starting. The planer is operated in the usual manner from the tumbler, and the master switch automatically varies the speed of the motor at each reversal. This type of drive has the desirable feature of eliminating the mechanically operated speed variators and is quite simple in operation. It provides a very flexible arrangement when variable speeds are desired. This is especially true on the smaller sizes of planers.

Probably the most interesting motor application to planers in recent years is the reversible-motor drive. While it cannot be claimed that the application of this type of drive is new, it can be stated that the drive approaches more nearly the ideal planer drive than any other method heretofore used. By coupling the motor direct to the first driving shaft, the entire reversing mechanism, pulleys and belts, are eliminated and all the objections before enumerated are successfully overcome.

The motor is an adjustable-speed motor, having a speed range of 1 to 4 so that a large range of cutting speeds from 25 to 50 ft. per min. can be obtained. A double set of resistances is provided making it possible to vary either cutting or return speed independently of the other. This arrangement has also simplified the problem of variable speeds in connection with this drive.

The operating mechanism is handled in exactly the same manner as is the standard belt-shifting type planer, so that no complications are encountered by the operator. Two predominating features in this type of drive are the total absence of belt slippage under heavy cutting and the lower peak loads at the moment of reverse. Table 3 shows the superiority of these two features over the belt drive.

It can be said that the reversible motor drive as applied today furnishes about all that can be desired of an efficient planer drive.

The study of fatigue of the operator and easy control of the machine is receiving quite a lot of attention in almost every machine operation, and there is no doubt but that great possibilities in this direction exist in machine-tool construction.

Power operation of heavy machine parts seems to have found a permanent place in the construction of all classes of

[illegible]. There is an increasing demand for elimination of lost time between cuts, and this feature has also found its way into the design of planers.

Rapid power traverse is now being generally used in manipulating planer heads in all directions. This is quite a departure from the standard construction in which the heads are operated entirely by hand. Experience has demonstrated that the new practice eliminates a considerable amount of wasted time throughout the day, and that it is also a decided help to the operator, as it saves him from undue exertion and fatigue.

The building of high-grade planers has established itself as an important factor in the machine-tool-building field. Many users seldom realize that, unlike smaller machine tools, the building of a planer requires a more extensive equipment of machinery, as well as a large number of costly fixtures and measuring instruments. The planer is necessarily a large and expensive machine, and proportionately larger returns are obtainable from it than from small machines owing to the higher expense or burden charged against it. The planer, therefore, should receive special attention from the time-study department.

GAS POWER PAPERS

DURING the past few years there have been marked improvements in gasoline-engine construction which have led to the extensive use of the high-speed type, particularly for aeroplanes. There will be a general discussion of this subject at the Gas Power Session of the Spring Meeting together with that of gas-engine regulation. Other papers treat of motor fire-engine tests and motor trucks.

THE PROBLEM OF AEROPLANE ENGINE DESIGN

By CHARLES E. LUCKE, NEW YORK, N. Y.

Member of the Society

THE problem of the aeroplane engine appeals strongly to every engineer because it is a problem of the lightest power plant. The lightest weight of engine proper per horsepower is to be secured first by obtaining maximum mean effective pressure at maximum speed: in other words, the product of the mean effective pressure and the speed must be a maximum. At the same time the weight of metal per cylinder, or per cubic inch of cylinder displacement per working stroke must be a minimum,—and with both of these factors the engine must be reliable in operation. So far, this reliability factor has been weakest, though lightness has been secured in engines good for short periods of running.

Not only must the metal weight of engine per horsepower be a minimum, but in addition the fuel weight to be carried must also be a minimum because, as can readily be seen, the fuel weight necessary for flights of any length predominates over the engine weight. For example: taking a half pound of fuel and oil per hour per horsepower as a fair value, it is readily seen how quickly that will catch up on engine weight when the latter is 4 or 5 lb. per horsepower.

In undertaking an analysis of the aeroplane-engine problem from the records, the only conclusion that can be drawn is along the line of type. Data are almost entirely lacking. On the question of general engine types, attention might be called to a few points:

The air-cooled motor has entirely failed in comparison with the water-cooled motor,—the reasons are perfectly sound and secure. The 2-cycle engine has given way to the 4-cycle type.

Fixed cylinders have prevailed over rotating cylinders. Odd cylinder arrangements of queer, freaky forms have all been relegated to the scrap heap in favor of a few modern arrangements. The standard cylinder arrangements of today, which are the survivors of what may be called the inventive period, or at least the first inventive period, are the six and eight cylinders in line and the eight, twelve and sixteen V's.

It really appears therefore that the one valuable result of all our experience has been the selection of a few typical arrangements which we are now compelled to study, as minutely as circumstances permit, for the purpose of standardizing and mechanically perfecting these particular types as standard machines which will run as reliably as our stationary engines and which can be manufactured as economically.

Taking up each of the factors of aeroplane-engine design that seem important, in as specific a way as seems proper, the first one I wish to consider is the value of efficiency and the relation of efficiency to minimum weight.

Plotting hours of running as abscissæ against weight of engine, with fuel and oil, as ordinates, for the air-cooled and the water-cooled types of motor, respectively, so that the intercept on the vertical axis represents the weight of engine metal alone, and the ordinates away from the axis represent the weight of metal plus fuel and oil, one finds that the two curves cross at some period of running beyond which, therefore, the water-cooled heavier engine, because of its lower fuel consumption, becomes lighter in comparison.

The metal weight of the water-cooled motor is about one and one-half times that of the air-cooled motor, and the slope of the combined-weight line of the latter compared with that of the former is as two is to one,—that is to say: the consumption of the air-cooled motor is approximately twice that of the water-cooled motor. These facts are responsible for the crossing of the lines.

Of the conditions for efficiency which bear upon this question of fuel weight, and which have led to the selection of the water-cooled motor as a type, the first is the compression. The higher the compression the higher the efficiency, and there is no limit until preignition occurs. Statements will be found in textbooks to the effect that there is a limit, but they are the results of mistakes in interpretation, and are erroneous. The amount of compression possible is limited, however, by the metal temperature and by the temperature of the mixture as admitted. Naturally, the warmer the mixture during suction, the sooner it reaches ignition temperature by compression. Therefore, suction heating is a limit. Again, the interior metal temperature, if it is high (as it is always), may cause trouble by contact with the mixture during compression, and

For presentation at the Spring Meeting, Cincinnati, Ohio, May 21 to 24, 1917, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. The paper is here printed in abstract form and advance copies of the paper may be obtained by members gratis upon application. All papers are subject to revision.

some portion of the mixture may be brought to its ignition temperature by hot-wall contact long before the main mass is brought to this ignition temperature by compression alone. It requires only one such hot spot to wreck a well-laid plan.

The next factor in efficiency is the mixture quality, and in this there are the following controlling elements: first, mixture proportions. Any excess fuel means direct waste, but it also means carbonization and fouling. Excess air quickly makes the mixture practically non-burnable. Therefore, mixture proportions must be accurately controlled—more accurately than is possible with any existing carburetor. Carburetors are not yet satisfactory, and as soon as satisfactory carburetors are secured from the standpoint of proportionality of the mixture, we may expect to see a further reduction in fuel consumption and more reliable operation.

Dryness of mixture is a matter of coördinate importance with mixture proportions. When mixtures are wet, that is not completely vaporized, the air and fuel cannot be uniformly distributed to the various cylinders by the manifold system. One cylinder will get a different charge from another, as can be easily proved by pressure gages. There are rarely two cylinders alike as to maximum pressures on a multi-cylinder engine using wet mixtures. Drying of the mixture will cure that fault, and also cure the carbonization that comes from the vaporization of the liquid in the presence of the burning gas when it has been admitted to the cylinder in a liquid state.

The third factor of the mixture question is homogeneity. However accurately the mixture may be adjusted as to fuel and air ratio, however carefully the mixture may be distributed, cylinder to cylinder, the fact remains that, in order to produce economical results, the charge in any one cylinder must be uniform in every cubic inch of it. It is not sufficient that the right amount of air be in the cylinder even if the fuel is vaporized when the latter is all in one corner.

Following mixture quality, the next factor in efficiency is rate of flame propagation with reference to piston speed. It can be shown that the explosion line of the indicator card following compression must be maintained vertical for maximum efficiency. Now, the rate of propagation is the one factor that tends to hold it vertical. If the propagation rate is high enough for a given piston speed, so that the explosion line is vertical, the efficiency will be high. But should the piston speed exceed a certain value, then the explosion line will begin to lean toward the expansion line, until by and by it becomes horizontal and merges into the expansion line, with a consequent large loss of work area and low efficiency or high fuel consumption. Therefore, there is for every given mixture a limiting piston speed that cannot be exceeded without destroying efficiency, and we are now approaching that speed in aeroplane engines.

The next related factors are mean effective pressure, and speed. These are the prime factors for the output of a cylinder.

If the mean effective pressure were constant, then horsepower with reference to speed would follow a straight line. The mean effective pressure is not constant as the speed varies, however. Therefore, plotting horsepower against speed gives a curve having the general form of concave downward and consisting of several separate portions, each worthy of study. There is usually a straight portion over a given speed range, during which the mean effective pressure is constant. For lower speeds the mean effective pressure is lower, and for higher speeds the mean effective pressure is again lower. From the point where, with increasing speed, the straight line becomes a concave-downward curve, the mean effective pressure is decreasing as speed increases, until at the point where the tangent to the curve becomes horizontal, the rate of increase of speed is exactly equal to the rate of decrease of mean effective pressure. At a little higher speed mean effective pressure decreases faster than speed increases, and finally the curve drops down toward zero power.

So much for the facts. An analytical engineer cannot be content with those facts, however, but finds it necessary if he is to apply a cure to go behind the facts to ascertain the reasons. The first step in doing that is to determine the volumetric efficiency of the engine by measuring the air and fuel, and comparing the total volume of mixture taken in, with the piston displacement. If the volumetric efficiency be plotted against the speed, much light is thrown on the situation. In the first place the volumetric efficiency falls off in the region of very low speed, where the mean effective pressure is low; it is constant over the region of constant mean effective pressure, where the horsepower speed line is straight, and then at some high speed it again decreases. It is clear, therefore, that curvature of the horsepower-speed line is due to a corresponding variation of volumetric efficiency. It may be found, however, that at some high speed the horsepower-speed line falls before the volumetric efficiency. This calls attention to the fact that the falling-off of mean effective pressure at high speeds may not be due primarily to volumetric efficiency but to other causes, and recognition of this starts a search for those causes.

The first of these causes is too slow a combustion, or too high a piston speed. That is to be corrected by adding an additional ignition source, or by moving the spark plug from a side wall to a center point. Igniting at more than one point or at a more central point will cure this defect, and again cause the dropping points of both horsepower-speed and volumetric efficiency-speed curves to lie on the same speed line.

Again, it will be found that a change in the valve setting changes this mean-effective-pressure curve at both ends, but every change in the valve setting also changes the mean effective pressure, and the volumetric efficiency is itself the direct measure of whether or not one has the best valve setting.

Now, it is curious that most people have played with cams and adjusted them back and forward by guesses, and have never bothered about the air meter, which is the only positive means of arriving at best cam forms and valve timing for sustained mean effective pressure at high speeds.

Many more analyses along the above lines could be given, but enough has been said to call attention to this most important means of studying the problem of maximum power at high speed, not only revealing what is the matter but pointing out clearly the direction in which to correct the fault.

So much for efficiency and mean effective pressure, or efficiency and horsepower per cubic foot of cylinder. Those two factors bear directly on the fuel weight to be carried and the output per cubic foot of cylinder. What will be the weight of that cubic foot of cylinder? This has to be judged both by qualitative and quantitative analysis. It is impossible to give any quantitative analysis without long mathematical treatment, so I will undertake only the qualitative analysis.

The first point in qualitatively analyzing unit metal weight of the multi-cylinder engine is to recognize that the engine can be divided laterally by planes into sections of one cylinder each. The end sections are the same as each other, but are different from the intermediate sections. Therefore, to study qualitatively the relative weights of two typical constructions,

the mind must be concentrated upon these sections, each one of which includes a cylinder, a piece of frame, a piece of shaft and the other parts that go with the section.

From this point of view, consider multiplication of cylinders in line vs. radially or circumferentially. It will appear that the weight of the cylinder, piston and connecting rod, is just the same no matter how the cylinders are arranged, but the frame weight and shaft weight are reduced by any multiplication. It is clear also that, other things being equal, the lighter arrangement is circumferential rather than longitudinal multiplication.

Now, going back to the history of the situation, we find every conceivable combination has been tried, but these have finally crystallized to not more than two kinds, giving the V type engine and the engine with cylinders in line.

Considering the effect of cylinder diameter upon unit metal weight, it will appear that from the unit weight standpoint the cylinder diameter should be as large as possible, because the wall thickness of a cylinder is always greater than necessary for the stress for other structural reasons. A 1/16-in. cylinder of steel will not be stressed over, say, 10,000 lb. per sq. in. The cylinder could be made much thinner than this and still have a good working stress if there were not other structural objections to it. This being the case, the larger the cylinder for a cubic foot of displacement the less the unit metal weight in the wall, and the only limit to large diameter is good running.

Considering the stroke, as this is increased the metal in the cylinder piles up endwise, or axially, too fast with reference to volume, and therefore for minimum unit metal weight, the shorter the stroke the better. In proportion, we are using, normally, shorter strokes in aeronautical motors than in automobile engines for that reason.

Again, as affecting the metal weight, we have the connecting rod length. Clearly, the shorter the connecting rod the shorter the frame, and therefore the more metal saved. The only objection to the shorter connecting rod is an excessive angularity, which introduces stresses requiring metal thickening in other places.

The number of cylinders should be as large as possible up to the point where the weight of the connecting parts has to be increased. A 2-cyl. engine has less than twice the weight per cubic foot of displacement than a single cylinder, for the reason that the number of end supports for the shaft, etc., is not increased. Similarly a 3-cyl. has less than three times, a 4-cyl. less than four times, and so on; and the weight per cubic foot of displacement gets less and less until a certain number of cylinders—somewhere about six—is reached where the shaft diameter and the weight of the frame must be increased so as to retain the necessary stiffness, whereupon the saving in weight by multiplication is neutralized. This appears to be about the limit of saving by line multiplication.

The metal weight per cubic foot of cylinder displacement has to be taken up along the lines indicated, extending the study to the form vs. weight of each individual member. It will appear, as one examines the forms of these individual members, that one form is clearly susceptible of less weight than another—even with the same working stresses or with equal factors of safety.

The first of these studies should be undertaken with reference to cylinders. The first cylinders built were made of cast iron, with head, cylinder and jacket cast in one piece, and the valves being arranged in a side pocket—the ordinary T- or L-head construction. It is clear that the weight of the valve pocket is detrimental. The first step in any cylinder-weight reduction, then, is to take that pocket away, retaining the cast cylinder (on the assumption that we do not know how to make any other kind) and putting the valve in the head. This results in the valve-in-head construction, which is now practically universal, but which, strange to say, it took six or seven years to realize.

A similar instance of slow realization of facts exists with reference to the cast-iron jacket wall, which has no other function than to hold water. Cast iron for that purpose, especially in an aeroplane engine, is wasteful of material, so the next step is to get rid of the cast iron. When one stops to think how it is to be done, a structural difficulty becomes apparent, and therefore one must not too readily condemn the holding on to the cast-iron jacket. The difficulty is of course the necessity of providing openings for the intake or outlet from each valve, an igniter plug hole and at least two pipe connections for the jacket, and in an aeronautical engine under heavy stress there is some driving gear which requires fastenings. This naturally tends toward the use of a casting.

Suppose such a casting is used, with inlet and one exhaust valve each with a port leading out, and such valve seating in the head which turns down to form the cylinder; then the casting may be led around the top, forming the enclosure of the head jacket and joining the several outlets and coming down outside the cylinder. The cylinder-head jacket casting ends in the form of a skirt at about the level of the valve deck, and to this end a tube jacket can be added by any one of several possible fastenings. That is the next step: cast iron for the cylinders, head and head jacket in a one-piece casting, but with sheet metal for the jacket over the cylindrical barrel. It is a logical step, but it took several years to reach it just the same.

Proceeding along the same line of weight reduction, the next step is to cut away this cast iron joining the ends of the ports and forming the wall of the head jacket, and substitute sheet metal welded to the ports by the oxygen welding system. Wherever there are connections to be made for attachment of gears, there must be some additional supports welded or brazed on. The cast-iron cylinder is still there, and with cast-iron ports.

There is a fundamental objection to a cast-iron cylinder for aeronautical work, and it is a perfectly valid one. Cast-iron cylinders do not have to be very thick to be amply strong, so far as the gas-pressure stresses are concerned, but the fact remains that so long as they are cast iron, no one knows whether they are good cast iron inside or not, and the use of cast iron cut down to $\frac{1}{8}$ in. in thickness incurs taking some chances. Hence attention is turned toward steel.

Drawn steel or forged steel is a reliable material and a logical selection, so designers have sought means of using it; but when one stops to think how to use a drawn-steel tube for a cylinder, and get the necessary attachments on it, one soon recognizes that the matter is not so easy as it looks. That is the reason the adoption of the steel cylinder was so long delayed.

There are now several schemes developed for steel cylinders. The first of these is a steel cylinder of a drawn tube formed without a head, screwed into a separate head carrying the ports and the head jacket cast in one piece. This is rather a satisfactory way of attaching a head, but it involves more than one difficulty. When such a screwed head is set up against the shoulder, it is not at all clear just where it is going to stop; and to secure the proper position one must either scrape the faces or shim them—neither of which is a nice job. A further objection is the considerable weight of the cast iron in a rather

complicated casting, and also the inner wall of that cast iron is a stress wall, the stress of which must pass through the thread to the cylinder. There is no objection to using a casting if it is not stressed, but a casting under stress is not satisfactory and is to be retained only in the absence of something better.

Complete elimination of castings has been tried by using all steel and sheet metal welded together, but this did not prove satisfactory for a very interesting reason. A flat sheet-metal head on which the valves are seated will not remain flat, and a round valve seat will not stay round. Such sheet metal tends to warp out of shape, and with it the valves will not stay tight. However, the material does not break, which is something worthy of thought.

To eliminate the weld between the steel cylinder and head, another construction was developed. In this, a seamless drawn-steel shell with head just like a cartridge is used, and two holes are arranged in the head to seat the valves. It is evident that this is a structure which is sound against all kinds of stresses. It still has some of the difficulties of warping the seats, causing leakage of the valves; and when a valve leaks the amount of heat developed is tremendous. Once a valve starts to leak, it is only a question of a short time before it will be completely destroyed.

The particular construction of cylinder just described is rather difficult to attach to its jacket ports. It is interesting to note one case at least in which a satisfactory attachment has been worked out, and that is the Hispano-Swissa engine, now used on the European war front, and now also being built in this country. In this particular engine the entire outside of the cylinder is threaded, and the cylinders are screwed into an aluminum casting which is double-walled just like the cast-iron block casting of an automobile engine. The thread performs the double purpose of holding the cylinder in place and bringing its head up against the aluminum cast head which carries the ports, and also acting as a thermal bridge between the metal of the cylinder and the metal of the aluminum casting which carries the jacket water. Without the latter there would be poor thermal contact and overheating of the cylinder. While this construction is not entirely satisfactory, it is nevertheless very interesting and suggestive. It immediately calls attention to the fact that a water jacket may be made of an aluminum casting and the ports formed just as easily as in iron, the steel interior carrying the stress due to the interior gas pressures.

It is, however, quite feasible to get rid of the double aluminum wall down along the cylinder barrel into which this steel cylinder is placed and which carries the ports above, by leaving out its interior wall and retaining the outside, or even by stopping the wall just below the head as a skirt to take a short thin tube which may itself be of aluminum, ending at the bottom in a cast stuffing-box ring to act as a joint against the steel cylinder. That, so far as I know, represents the last word in this direction, the steel cylinder head being bolted up to the aluminum head-port casting at the valve seat bases, and not just pressed up against it by a remote thread.

Finally, there is to be noted the one-piece steel-forging construction for cylinder, cylinder head, ports and ignition holes, surrounded by a sheet-metal welded jacket, a very satisfactory though expensive construction.

These heads are themselves a subject of considerable study. We have first a plain head in which the valve inside diameter is half the cylinder less the width of seat, and half the bridge between the valves. Both valves have stems pointing upward and parallel. The plain cylinder, then, which can be made of a plain seamless-drawn steel cartridge, and which is so desirable structurally, limits valve diameter, and this is a factor against it. Valve diameter is a strong influence in volumetric efficiency and weight of charge, controlling, as it does, flow-resistance conditions. Naturally, designers must get the volumetric efficiency as high as possible by keeping flow resistance as low as possible. Therefore, the tendency is to go towards larger valves than is possible with the previous arrangement.

One variation in form for this purpose is the flat bulged head where the valve diameter is larger than before by the amount of the bulge. The flat bulged head is a very desirable thing for larger volumetric efficiency and higher mean effective pressure, but offers some difficulty in manufacture when one is making a one-piece seamless drawn-steel job, but not a serious difficulty.

Another suggestion for getting the same result is to bulge this head upward in the form of two flats and put the valves on the two inclines. It is perfectly clear that a very large increase in diameter can be secured in this way. The valve stems in this case are not parallel but diverge at any angle and the limit is reached when the angle is 180 deg., in which case they are horizontal.

The question of block arrangement of cylinders and their jackets vs. separate units, deserves some attention. In some cases each cylinder with its jacket and head is entirely separate. In other cases the jackets are cast or welded in a block form, around more than one cylinder—sometimes two and sometimes four, and in some cases six. It is clear that the more cylinders included in the jacket block, the less will be the weight of the jacket, because the length of the tangent to two jacket circles is less than a half circumference. But there are objections to the block, and in some cases it may not pay to use it.

In a case in point, a cast-aluminum block jacket was set down over four steel cylinders which were bolted to the frame by their usual flanges and studs. These cylinders gave trouble on the outer flanges, the end studs breaking off or pulling out. The trouble was caused by the crankcase running hot, expanding; and the aluminum-block cylinder casting running cool, because it was water-jacketed, not expanding. The cylinders being bent inward tore the stud ends right out.

Another point: the steel cylinder is naturally flexible, and it belongs—in fact the entire motor belongs—to that class of structures which should properly be termed flexible, exactly similar to bridge structures.

These flexible motors weave just as the engine of a steamship weaves. To attempt to hold one against springing is to attempt what is practically impossible. The cylinders of aeroplane engines should all be perfectly free to go as they will, and not be held on the top in any way. All the block arrangements of cylinders of the sort just described, are therefore objectionable.

Steel cylinders have a natural spring and give to them, and if let alone they will serve well, but attempting to secure them may result in serious distortions, or in highly localized excess stresses.

Proceeding in the same qualitatively analytical style, the complete paper takes up successively the problems of the piston, valves, valve gears, frame, etc., indicating how a gradual realization of conditions has led to modifications of design, and pointing out factors not even yet considered and making suggestions for meeting them. For instance, in connection with the valves the author makes a thermal study of the problem which, he says, has not been undertaken by anyone in the shops. He does the same for the piston, and the

crankcase be analyzed from its consideration as a stress member.

The paper sums up with the pointed statement that the aeronautical engine is emerging from the stage of invention to the stage of design, as a light, high-tensioned steel structure, consisting of seamless tubing and forged or welded steel parts, possibly formed in drop-forge dies. Add to that steel stress structure certain members, such as the piston, exhaust valve and guide, designed primarily for heat flow conditions and not for stresses. Add to that again certain closing members, such as the ports for the intake and exhaust, which can be very properly cast in aluminum, and the oil crankcase closure, which can be made of any desired materials.

TEST OF A MOTOR FIRE ENGINE

By HORACE JUDD, COLUMBUS, OHIO

Member of the Society

DURING the past ten years the city of Columbus, Ohio, has remodeled many of its horse-propelled steam fire engines and equipped them with motor-driven trucks so that now more than 70 per cent are motor-driven. The city also has two complete combination gasoline motor-driven and pumping units. One of these combination units, put into service in April, 1916, was loaned to the Ohio State University through the courtesy of the Columbus Fire Department for a more extended test than could be undertaken during the acceptance trials by the Inspection Bureau.

In view of the importance and value of the motor-driven engine in getting under way and reaching the fire, as well as the ability to change the motor instantly from propulsion to pumping, the writer offers the results of a performance test on this motor fire engine to those interested in fire prevention.

The motor fire engine unit was manufactured by the Seagrave Company, Columbus, Ohio, and consists of a motor-driven, direct-connected, centrifugal pumping unit combined with a hose truck. (Fig. 1.)

The motor is a 4-cycle, water-cooled, six-cylinder motor, 79.3 hp., A.L.A.M. rating, and of rugged construction to meet the requirements of fire service. The cylinders are vertical, T-head, cast separately, with integral water jackets. Cylinder bore is 5.75 in., stroke 6.5 in. The crankcase is parted horizontally through the plane of the crankshaft, the upper section supporting the cylinders and crankshaft bearings and the lower section easily removable and forming a reservoir for oil. There are two cam shafts, one on each side of the motor, with the cam gears located in the forward end, encased but easily accessible. The intake and exhaust valves are 2.625 in. in diameter with 13/32 in. lift.

Forced feed lubrication is used. The cooling water is supplied by a separate centrifugal pump operated from the cam shaft. The carburetor is of the float-feed type with automatic auxiliary air intake and is controlled by the throttle lever. The ignition is of double type, (*a*) Bosch high tension, waterproof magneto for one set of spark plugs, (*b*) current from a storage battery through a timer to the second set of spark plugs.

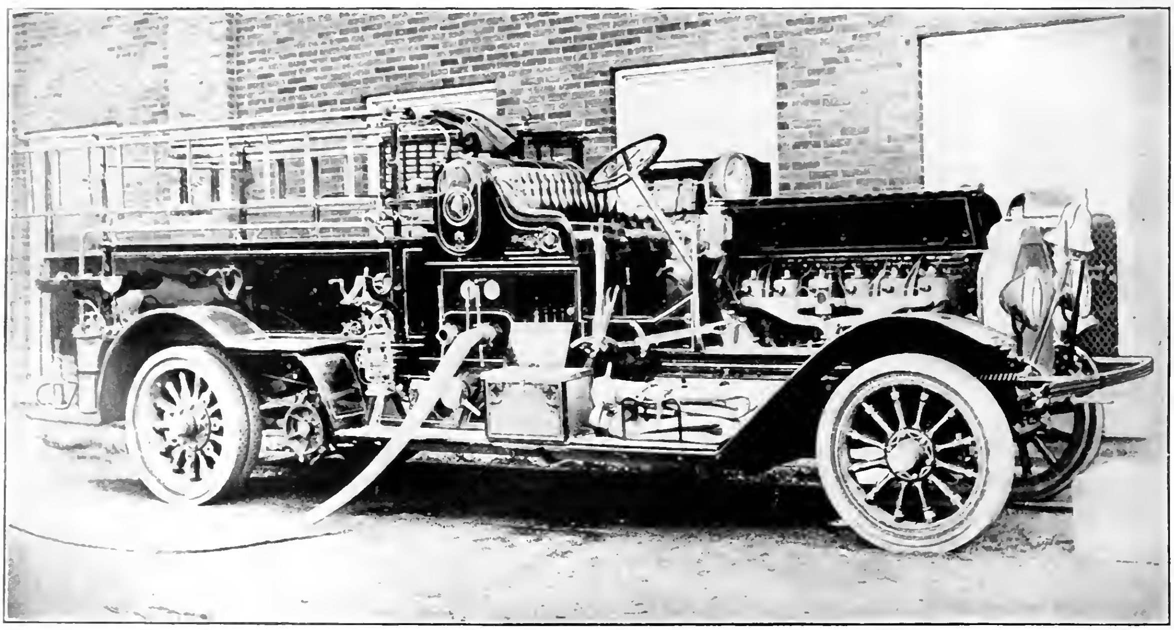

Fig. 1 The Motor Fire Engine

The centrifugal pump (Fig. 2) is a 4-stage (two stages for each impeller) turbine pump mounted under the driver's seat about midway between the front and rear axles. The casing is of bronze and includes in one piece the guide, or diffuser, vanes, and the water passages connecting the successive stages. The two bronze impellers are mounted on a hollow steel shaft which fits over the drive shaft to the differential and is driven by hardened steel gears which can be thrown out of mesh when the engine is on the road.

Each impeller has 12 vanes 1 in. wide and 9/16 in. net depth of water passage between the vanes. There are six diffuser vanes surrounding each impeller. (Fig. 3.) The water enter-

For presentation at the Spring Meeting, Cincinnati, Ohio, May 21 to 24, 1917, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. The paper is here printed in abstract form, and advance copies of the complete paper may be obtained by members gratis upon application. All papers are subject to revision.

[1] This paper is based on the results embodied in the thesis work of Messrs. E. W. Leatherman, H. V. Walborn, and E. R. Wilson, graduates in Mechanical Engineering, Class of 1916.

ing at the center of the pump passes into the first stage on the inner half of one propeller, is thrown out by centrifugal force through the diffuser vanes and, passing around the impeller through the water passage, enters the second stage on the other side of the same impeller. From the second stage it enters the third stage on the inner side of the second impeller and is discharged into the other side of the impeller

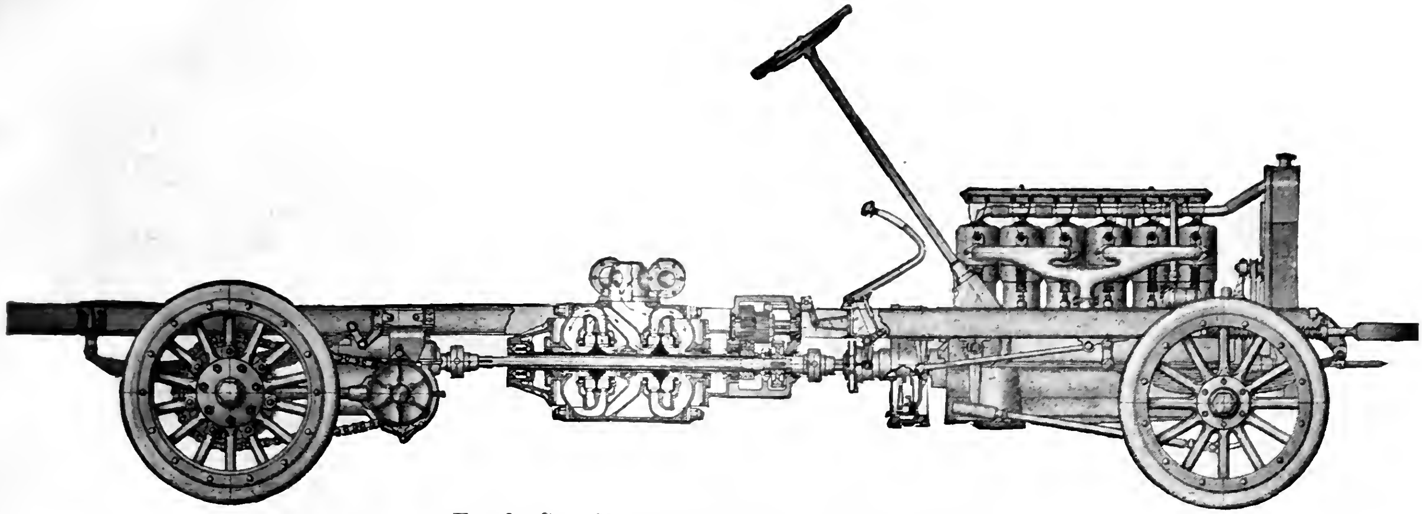

Fig. 2 Side View of Centrifugal Pump Chassis

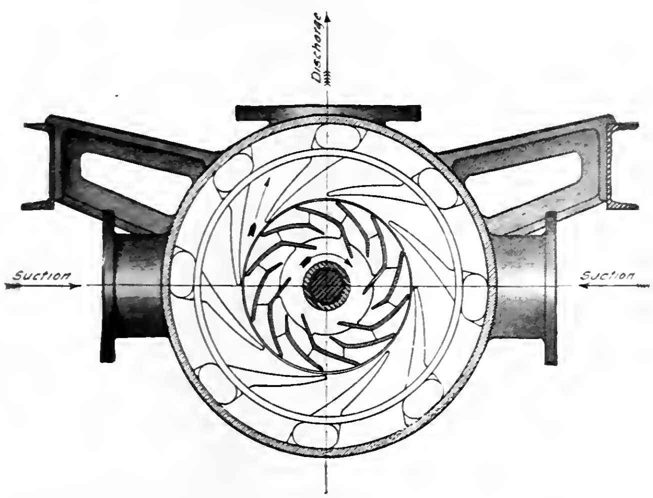

Fig. 3 Sectional View of One Stage of Pump Showing Impeller and Diffusion Vanes

(fourth stage) and from thence it passes into the discharge line. Since the water enters both impellers on the inner side the end thrust is practically eliminated, although end-thrust shaft bearings are also provided. Two suction connections and three discharge connections are provided.

When necessary the pump may be primed by means of a rotary vacuum pump, which will exhaust the air and enable the pump to be put into operation in about 20 sec.

The speed ratio of the pump and engine is 2.06 to 1. The speed range of the motor during the tests was about 800 to 1100 r.p.m., corresponding to a speed range of the pump of about 1650 to 2270 r.p.m. The rated capacity of the pump is 750 gal. per min. at 120 lb. net pressure at the pump discharge.

The purpose of the tests may be outlined as being to determine:

a The capacities of the fire engine when working against the usual range of pressures and with such sizes of fire nozzles as are commonly used.

b The fuel consumption of the engine.

Such a series of tests required the accurate measurement of the fuel used, the water pumped, and the pressures maintained at engine and nozzle.

The tests were carried on in the hydraulic laboratory of the University, where the water was taken from one of the large cisterns, or bays, 25,000 gal. capacity, as shown in Fig. 4, through three lengths of 5-inch standard rubber suction hose, and was discharged through the desired length of hose line, first into a series of tumbling bays and finally into the suction bay after passing through an 8-in. by 20-in. standardized rectangular weir. The discharge of the nozzles was also read at the jet by means of the pitot gage, or piezo-

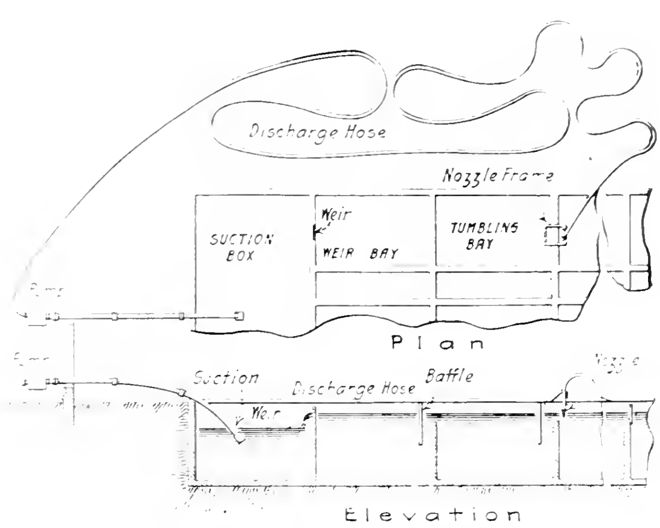

Fig. 4 Arrangement of Apparatus

meter, now widely used in fire-service work to give instantaneous readings of the nozzle discharge. The gasoline used was weighed on carefully calibrated platform scales. The pressures at the engine were taken by the regular service gages and their readings corrected for error. The pressure drop in the hose line was taken by means of a specially con-

[illegible] connection for the pressure gage which was located at the hose coupling as shown at A in Fig. 5.

The discharge hose was taken from the city service and had seen considerable use but was in fair condition; it was rubber lined cotton hose with nominal diameter of 2.5 in. and average actual diameter of 2 11/16 in. The smooth conical nozzles, shown in Fig. 6, were taken from the regular equipment of the

FIG. 5 FIRE STREAM FROM TWO-HOSE SIAMESE UNION

and continued for 30 min. for the runs with double line using Siamese hose connection, and for 20 min. for the runs using single-hose lines. At the completion of the runs the engine was stopped at the instant and the gasoline tank refilled, and the amount put in was taken as the equivalent of the amount used.

The Siamese hose union was a 4-hose connection, but in this

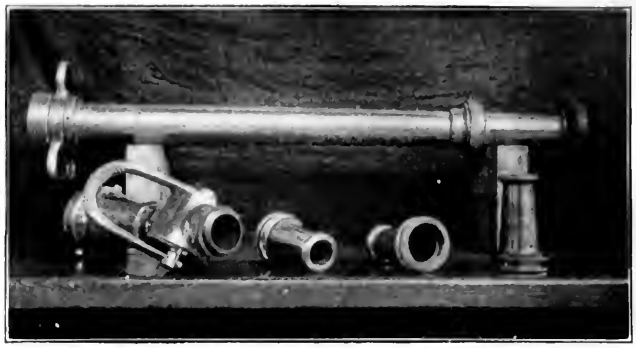

FIG. 6 PLAY PIPES AND SMOOTH NOZZLES

case was connected to the pump with but two 250-ft. lengths of 2.5-in. hose. To the Siamese union was attached the 12-ft. length of 3.5-in. hose with the play pipe and the 1.5-in., 1.75-in., and 2-in. smooth nozzles. Single-hose lines, both 250- and 500-ft. lengths, were used with 1.125-in., 1.25-in., and

[1] For Siamese connection, this gage is located at end of 2.5-in. hose, 12 ft. from nozzle

engines. The sizes chosen were those most commonly used in the city fire service.

During the test the pump was quickly brought up to running conditions, and with a full gasoline tank the runs were started

1.375-in. nozzles. The range of discharge pressure carried at the pump was from 95 to 250 lb.

Readings were taken for the whole run of the gasoline used, every five minutes of discharge pressure at the pump, the

revolutions of the motor, the pressure drop in the line, and every minute and a half of the weir readings.

DATA AND RESULTS

The average values for *the observed data and the calculated results* from these data will be found in Table 1.

Fig. 7 represents the *important results for the motor fire engine*, as a unit. Here are shown the total gallons of gasoline used per hour for water horsepowers at the pump, ranging from 20 to 60; the gallons of gasoline used per hour per unit horsepower; the number of heat units supplied, and the duty of the pump.

The number of heat units is taken as equal to 117,000 B.t.u. per gallon (59.8 deg. Baumé, 0.738 specific gravity, 19,000 B.t.u. per lb.).

Duty is defined as the number of foot-pounds of work done per 1,000,000 B.t.u. supplied.

$$\text{Duty} = \frac{60 \times 33{,}000 \times 1{,}000{,}000}{\text{Gal. gasoline per hp. per hr.} \times 117{,}000} = \frac{16{,}920{,}000}{\text{Gal. gasoline per hp. per hr.}}$$

The maximum capacity obtained during the test was 745 gal. per min., at 122 lb. pump discharge pressure with a 2-in. nozzle attached to a Siamese union with two hose lines each 250 ft. long, as shown in Table 2. This discharge is slightly below the rating of 750 gal. at 120 lb. net pump discharge pressure, and is accounted for by the fact that a 2-hose line instead of a 3-hose line was run from the engine.

TABLE 2 MAXIMUM CAPACITIES FOR VARIOUS SMOOTH NOZZLES UNDER CONDITIONS OF TEST FOR MOTOR FIRE-ENGINES

Diameter nozzle, in.	Discharge press. at pump, lb.	Maximum capacity by weir, gal. per min.	Pitot gage readings, lb.	Capacity by pitot gage, gal. per min.	Deviation of pitot gage from weir, per cent	No. and length of hose line, ft.
1.121	249.6	360	105.0	384	6.4	One 50
1.246	242.0	383	71.0	393	2.4	One 50
1.370	236.2	399	57.3	425	6.0	One 50
1.500	157.3	637	94.9	656	3.0	Two 2[illegible] with [illegible]
1.750	133.5	693	61.3	718	3.4	Two 2[illegible] with [illegible]
2.000	121.9	745	43.3	788	5.5	Two 2[illegible] with [illegible]
Two of 1.246	134.0	720	64.5	747	3.7	Two 2[illegible]
Average		...	....	...	4.3	

The capacity as indicated by the pitot gage is seen by Table [illegible] average 4.3 per cent higher than that by the calibrated weir.

The gasoline used by the motor fire engine may be read from the total gasoline curve, Fig. 7. The range of water-horsepower output was from 18 to 60 hp., with most of the tests grouped about 18, 40, and 55 horsepowers.

The average results as read from the curve are as given in Table 3.

TABLE 3 AVERAGE RESULTS FROM FIG. 7

Water-hp. output	Gasoline per hr., gal.	Gasoline per hr. per water hp., gal.	Heat units supplied per hr. per water hp., B.t.u.
20	5.45	0.272	32,000
40	8.72	0.218	25,500
60	14.35	0.240	28,000

The curves (Fig. 7) show that the [illegible] working point for the engine is about [illegible] at which point the least gasoline per [illegible] and hence a horsepower is obtained with [illegible] of heat units.

Assuming 50 per cent for the overall [illegible], which would seem to be a reasonable figure for [illegible] pump and hose line, it is seen that the most [illegible] conditions are obtained when the probable engine output is [illegible], which is its rated power.

For 40-hp. output, 0.218 gal. of gasoline per hr. per [illegible] used, which is equal to 1.74 pints of gasoline per [illegible]. An average value of 1 pint per hour per brake horsepower was obtained in 1912 on a 4-cylinder Seagrave motor similar in type. The value of 1.74 pints for the complete fire-engine unit seems a consistent figure when the frictional resistances of the pump and hose line are taken into account.

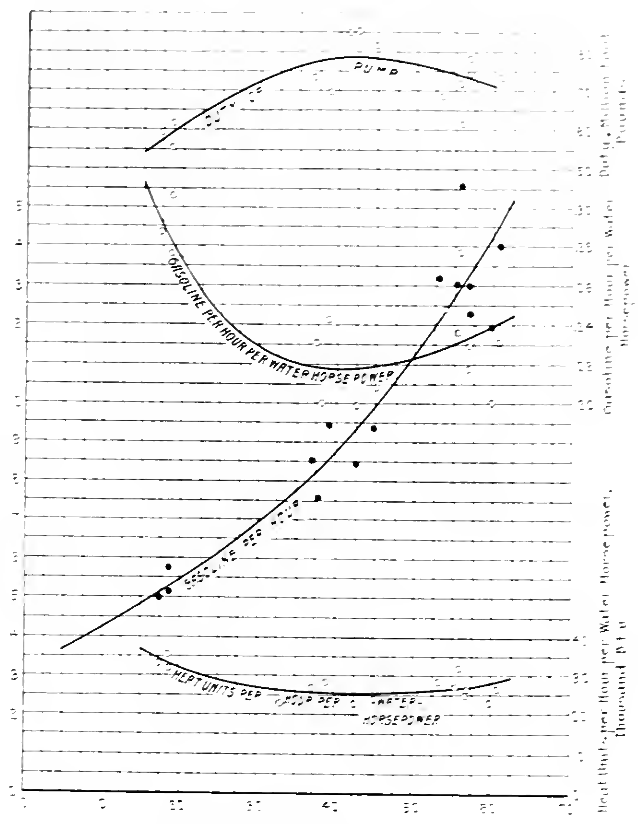

Fig. 7 Performance Curves for Motor Fire Engine

The advantage of the gasoline-driven engine is most noticeable when the comparison is made with the horse-drawn steamer, for the motor fire engine is able to reach the fire in half the time, is readily converted from the locomobile to the pumping engine, and is more easily and economically operated, with the expense of maintaining the proper number of horses entirely eliminated.

The paper closes with a comparison of the gasoline-driven engine and the horse-drawn steam fire-engine unit, leading to the conclusion that the motor fire engine is fully the equal of the steam fire engine in fire-stream capacity, and, except as to a slightly higher fuel cost at prevailing prices, is without doubt its superior in steadiness of pump action, as a time saver, in flexibility, in ease of operation, and in reduced cost of maintenance, especially when compared with the horse-drawn steamer.

THE DESIGN OF MOTOR TRUCK ENGINES FOR LONG LIFE

By JOHN YOUNGER, BUFFALO, N. Y.

Member of the Society

THE [illegible] of a motor truck engine is naturally one where the "[illegible]" compromise. An intense [illegible] to the exclusion of everything else, would result in [illegible] which would be too heavy, too bulky, and [illegible] to run.

An [illegible] definition of *long life* would, therefore, be "[illegible] which is something more than the average expected life, based on present day knowledge and all-around conditions."

At the present day a life of 50,000 miles, without overhaul, would be considered long. This would correspond to a continuous run day and night for 12 months, at a speed of about 100 r.p.m., with no attention beyond oiling and fueling. The load will fluctuate between less than zero (as when in coasting downhill with clutch in, the chassis drives the engine) to the full power of which the engine is capable. The majority of the hauling will be done at an average of 1/3 full engine power. An engine should be capable of at least five or six overhauls, or 300,000 miles, before renewal of the major parts.

This does not look at all severe to the casual glance of the power house engineer, but when one considers that this power plant is operating under widely varying temperatures, power and speed conditions, and that its various axes are constantly changing relatively to the bed to which it is fastened, it will be seen that the problem of long life is not so simple as it looks.

Long life depends on three factors: (1) *Design*, (2) *Manufacturing excellence*, (3) *Operating conditions*.

DESIGN

This may be considered under headings such as: *a* bearing surfaces, *b* lubrication facilities, *c* materials used, *d* factors of safety, *e* general design and use of governor.

Explosion Pressure. All calculations should be based on full load, not on average load. This can be taken as an explosion pressure of 300 lb. per sq. in. on the piston with a 22 per cent compression volume.

Connecting Rod Bearings. The pressure per projected square inch should be about 700 lb. per sq. in., excluding area of oil leads and fillets at ends, or 1 sq. in. per 2.33 sq. in. of piston area.

Oil is conveniently introduced through a hole in the crankshaft, and the bearing may either be grooved with a slightly spiralling oil groove around the whole circumference, or a groove around the bottom half only, or a series of slots or labyrinth checks on the sides, or even no grooves at all. Any of these methods prevent ridge wearing on the crankshaft.

The bearing itself should be a thin shell of hard babbitt metal about 1/32 in. thick, backed up by a thick shell of hard bronze running on a case-hardened or otherwise hard surface. This gives the advantages of the babbitt as a bearing metal, and prevents it from pounding out. The bronze should be carefully turned and have peg holes in it to give perfect union between the two. The running clearance should be small, between 0.0015 in. and 0.0025 in., satisfying practically all truck engines. The split surfaces should be carefully fitted together to prevent rocking or cater-cornered work.

Gudgeon or Wrist-Pin Bushings. Owing to the slight oscillatory motion, pressures may be higher. Under the conditions of space and the necessity for keeping down the weight of reciprocating parts they may be as high as 1800 to 2000 lb. per sq. in. (or 1 sq. in. per 6 sq. in. of piston area).

Lubricating oil should be brought by a small tube (where pressure lubrication is used) direct to the bearing and allowed to ooze out. The majority of bushings are at present lubricated on what might be called the "chance" method,—the chances being, however, chiefly against The metal should be a very hard chill cast phosphor bronze, running on a case-hardened steel surface.

Running clearances should be kept exceedingly low, 0.00025 in. being satisfactory. Very little tolerance should be allowed.

Pistons. The side bearing pressure is low, inasmuch as the facilities for lubrication are poor. Sixteen pounds per projected square inch is satisfactory. The piston should be as light as possible consistent with strength, so as to minimize the loads due to the reciprocating masses.

Three rings above the gudgeon pin are ample. They should be thick radially, and preferably of the concentric type, to even the pressure on the slots and prevent them wearing away. The S.A.E. standard for piston ring grooves is $G = \frac{1}{8}(0.01\,D^2) + 0.005$ where G is depth of groove, and D is nominal diameter of piston. A pressure of about 10 to 12 lb. per projected sq. in. is ample to keep the rings against the cylinder walls.

The piston should be made of a softish gray cast iron, running against a harder cylinder metal. The clearance should be great at the top to allow for expansion due to heat, being four times the piston diameter in thousandths above the top ring, and equal to it in thousandths on the skirt. This bearing surface is, as a rule, relieved around the gudgeon pin.

Cylinders. Cylinders should be of a hard, close-grained, high tensile strength cast iron. Its scleroscope hardness (though this is of doubtful value) will be found to be about 35. It should be made thick enough in the walls so that actually about 0.060 may be ground off the diameter to take care of wear, without causing weakness. For a 5-in. bore cylinder, 5/16-in. walls are sufficient.

Crankshaft. Three bearings—front, center and rear—are considered ample for a 4-cyl. truck engine. Consider the area of the connecting-rod bearing (big end) as 1, then the front and center bearings may have an area equal to 1 and the rear bearing 1.5. If splash or trough system of lubrication is used, the areas of the front and center bearings should be increased to about 1.2.

An approximate rule for the diameter of crankshafts in the usual sizes of motor-truck engines, is that the square of the cylinder bore shall be twice the cube of the crankpin. This gives a 2-in. shaft for a 4-in. bore engine, and about a 2 5/16-in. shaft for a 5-in. bore engine.

Running clearances lie between 0.0015 and 0.003 in., depending somewhat on the nature of the lubrication.

The bushings should be similarly constructed to those on the connecting-rod big ends, except that the spiral oil groove will probably be found preferable to give a continuous supply of oil to the connecting-rod bearings.

The material should preferably be about 0.40 to 0.50 per cent carbon steel, carefully heat-treated to give a tough, hard

For presentation at the Spring Meeting, Cincinnati, Ohio, May 21 to 24, 1917, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. The paper is here printed in abstract form and advance copies of the complete paper may be obtained by members gratis upon application. All papers are subject to revision.

surface (scleroscope 36 to 40). The larger-diameter shafts should have a percentage of chromium and nickel to ensure better heat treatment and resistance to fatigue.

Low-carbon, case-hardening material is sometimes used, but the shaft has to be increased in diameter to compensate for the lessened resistance to fatigue.

Good-sized fillets, no machine-tool scratches and general smoothness of outline will materially help long life.

Camshafts. Camshafts should be made of a low-carbon steel, case-hardened on the wearing surfaces. The bushings should be of a good grade of phosphor bronze. Three bearings are ample for a 4-cyl. car. The diameter of the shafts should be from 1 in. to $1\frac{1}{8}$ in., for the sake of smooth operation. The projected area of the bearings, front to rear, should be approximately 4 sq. in., 3 sq. in. and 2 sq. in., depending somewhat upon whether oil pumps or governors are driven from the camshaft.

Valves. The cams operating the valves should be so designed that just before the valve seats itself the velocity will be considerably diminished, allowing the last few thousandths of its travel to take place in a comparatively long time. This prevents the valve hammering on its seat. It does not interfere with the fuel economy or power, but gives quieter action.

A 45-deg. valve seat is advisable, as carbon will not be driven into the seat, but will more easily clear itself.

Valves containing a percentage of tungsten from 2 per cent upwards are most satisfactory as regards life and freedom from warpage. By scleroscoping them while hot, they will be found to hold a hardness of over 40. Cast iron remains about 30, while other steel and nickel alloys drop to 25 or lower. The tungsten valve has thus a reason for its long life.

Sundry Parts. The rest of the engine should be designed in proportion, such as wide faces on the timing gears and ample bearings for their spindles. The water pump should have ample bearing area, and if of the centrifugal type proper provision should be made for the thrust of the blades.

Studs may be used for fastening down the cylinders, but they should have a length equal to twice their diameter screwed into the aluminum alloy, if such be used. A coarse thread is necessary, but for all purposes where aluminum is concerned, best results are obtained by the use of through bolts.

LUBRICATION

Considerable change has taken place in this in the last few years, although even yet all questions have not been settled, and cylinder lubrication is still somewhat on the hit-and-miss principle.

The method most in favor at present is to carry a supply of oil, about one gallon, in the crankcase of the engine, and pump it under a pressure of anything between 2 lb. and 20 lb. per sq. in. to a header pipe, from which issue leads to the crankshaft main bearings, and often the camshaft and timing-gear bearings. The surplus oil is by-passed by a regulating valve back to the crankcase. This oil and that which has done its work in the cylinders and crankshaft and various bearings drains down to the bottom of the case through a strainer and thence into the pump to renew the circuit.

When the oil gets dirty enough—or say every 300 miles or so, it ought to be thrown out and replaced with clean oil.

The system described works surprisingly well when it is considered that a certain amount of gasoline filters past the pistons and dilutes the oil—that some of the aqueous products of combustion also get past and help form an emulsion.

However, it can only be a matter of time before the adoption of some much better sys[illegible] each bearing in predetermined [illegible] the market and most of them are [illegible]

Incidentally, as a point of design [illegible] for the driver to make sure that [illegible] and of ample quantity.

MATERIALS AND FACTORS OF SAFETY

Naturally extreme consideration has not [illegible] weight, as has been in the case of aeroplane engines [illegible] 2[illegible] lb. per hp. has been reached. A fair weight for a motor truck engine is nearer 20 lb. per hp. at a piston speed of 1000 ft. per min. Aluminum is used for the crankcase and its covers. Cast iron is used for the cylinders and pistons. 0.40 to 0.50 carbon steel is used for the crankshaft and connecting rods. Case-hardening steel is used for the camshafts, valve tappets and gudgeon pins.

In order to ensure the proper factor of safety being maintained, it is advisable to scleroscope each part for correctness of heat treatment or hardness. Forgings like connecting rods, camshafts, crankshafts, should be straightened before machining.

The general design should be such that extreme climatic conditions can be guarded against. Roads, for example, in winter time are exceptionally bad, causing a weaving of the bed of the engine as would correspond to one of the wheels being lifted 12 in. off the road. The engine should be mounted so that no stress due to this will come on the moving parts.

The engine power should be ample for its work. Too much gear work is detrimental to long life. The transmission reduction should be such that the great majority of road work should be done on high gear. For instance, the hilly city of Cincinnati requires a lower transmission ratio than would the comparatively level cities of Buffalo or Cleveland. This prevents the engine from working at maximum capacity for too much of the time.

Speed should be carefully limited. A maximum piston speed of 1000 ft. per min. is desirable, and drivers and purchasers should be educated to the economy of a governor which will enforce this. The governor should be so designed that it will not restrict the power, but should go in or out of action with a maximum 5 per cent variation in speed round the predetermined point.

MANUFACTURING EXCELLENCE

Too much stress cannot be laid on this. Poor workmanship cannot be tolerated in an internal-combustion engine. Cylinders should be ground to a maximum tolerance of 0.002 in., as should pistons, and in addition, a process of selection must be used which will ensure pistons on the high limit being put into cylinders of the low limit. The running clearances should not vary by more than 0.002 in.

Pistons, complete, should be weighed, the maximum variation in any one of a set being not more than ½ oz. Similarly, connecting rods should be weighed and balanced, the variation in one of a set being not more than ½ oz., with the ends varying also by as little.

Connecting-rod and crankshaft bearings should be selected so that a maximum variation from standard running clearance of 0.001 in. plus or minus should be adhered to.

There is some diversity of opinion as to the best way to finish these bearings, but the writer believes that a reamed

surface is superior to the hand and hand-scraped one. Reamers mounted on a rigid bar will line up crankshaft bearings in a way impossible by the hand reamer. Further, the surface left is as nearly round as possible, corresponding to that of the ground crankshaft. The personal element in hand scraping is entirely eliminated.

Crankshafts should be ground smooth with a maximum variation of 0.0005 in. in diameter and 0.001 in. eccentric. Each shaft should be scleroscoped at every bearing. Similarly with the camshaft, pump and magneto drive bushings and so forth, a uniformly high standard should be insisted on.

It follows naturally that rotating parts should be put in static and dynamic balance.

When the engine has been assembled, it should be placed on a stand and run in. Here again opinions differ, but the writer believes a run of at least 30 hours, at a piston speed of about 800 ft. per min., varying the load from zero at the start to practically maximum for one or two hours at the finish, is necessary.

Most of this test, if indeed not all, should be done with some kind of fuel, either gas or gasoline, to get the engine thoroughly warmed up. This will ease off the high spots, let the valves find their seats, and generally take the harshness out of the engine.

At the end of this run, the engine should be partially disassembled and valves reground, piston rings touched up, carbon cleaned and the engine carefully inspected for signs of wear or scoring flaws.

When reassembled, the engine is ready for work.

OPERATING CONDITIONS

One of the secrets of success in gasoline engines is oil and lots of it. After a comparatively short run, the oil (in the average system) is contaminated by gasoline and carbon. It should be drained out every 150 to 300 miles and replaced entirely by fresh oil.

The strainers leading to the pump should be kept clean and inspected frequently.

About once a month the whole engine should be cleansed by washing it out with kerosene, turning the crankshaft by hand and thoroughly draining the kerosene all out.

Screens should be provided on the air intake to the carburetor to prevent entrance of road dust as much as possible.

Gasoline should be cut down in the carburetor as much as possible, not only for the sake of economy in consumption, but also for the prevention of harmful effects by an overplus.

The point of ignition should be properly controlled, so that evils following an "advanced spark" will not result.

Drivers should change to a lower gear immediately there are signs of the engine laboring.

Drivers should be carefully selected and trained men. Good horse drivers make good truck drivers, as they are accustomed to giving care and attention to their "motive power."

A regular system of inspection should be carried out by a good mechanic to detect any signs of trouble developing.

It is understood that hilly country or heavy roads will materially add to the work the engine has to do, and that the life will be proportionately shortened and inspection and overhauling will have to be done more frequently.

The amount of crude petroleum delivered to refineries and consumers in February 1917 from the Oklahoma-Kansas field was 4,546,461 barrels, from the Appalachian field 2,105,744 barrels, and from the Lima-Indiana field, 1,421,520 barrels.

THE RELATION OF PORT AREA TO THE POWER OF GAS ENGINES AND ITS INFLUENCE ON REGULATION

By J. R. DU PRIEST, MOSCOW, IDAHO

Member of the Society

The early forms of gas engines were of comparatively small power, and as engines of this size do not usually require close speed regulation, the "hit-and-miss" system of governing was applied quite successfully. As the machine was improved in design it became more reliable in service and was gradually applied to other classes of service in competition with steam engines and under conditions requiring better speed regulation.

This resulted in multi-cylinder engines to give more uniform turning moment, and "cut-off" and "throttling" governors to give power on every cycle. These improvements have enabled the modern gas engine to give excellent and reliable service, and to have a field almost as broad as the steam engine. However, designers are still striving to improve the machine in every way possible, adapting it to cheaper grades of fuel, improving its speed regulation, simplifying its mechanism, and making it more reliable and economical, so that its field of service may be still further increased.

The object of this paper is to present a method of determining the port area required for any fractional load on a throttling gas engine operating on the four-stroke cycle, and to suggest a means of admitting the fuel so as to get the same degree of speed regulation throughout the full range of load.

DISCUSSION OF PROBLEM

The function of a constant-speed governor on an engine is to control the speed within certain limits (depending on the class of service for which the machine is designed), while the load varies anywhere within the capacity of the engine.

In all types of governors dependence is placed on the change in speed of the governor to effect regulation, and when this governor is driven from the main engine, the speed of the engine must change before the governor can act on the valve gear and exert any influence over the energy supply.

If the load on the engine increases, the order of changes in the governing system is as follows:

a Speed of the engine decreases

b Speed of the governor is reduced

c The change in the position of the governor, due to the change in speed, shifts the valve gear and supplies more energy to the engine to enable it to carry the increased load, and at the proper speed

d The speed of the engine increases, due to the increased supply of energy, hence the speed of the governor increases, and the cycle above described is repeated in the reverse order. This action tends to produce a "hunting" effect on the valve gear and governor until the energy supply is properly proportioned to the existing load.

Apparently, the most desirable results would be obtained if the governor were so connected to the valve gear that equal movements of the governor collar would correspond to equal changes in load.

For presentation at the Spring Meeting of The American Society of Mechanical Engineers, Cincinnati, Ohio, May 21 to 24, 1917. The paper is here printed in abstract form and advance copies of the complete paper may be obtained gratis upon application. All papers are subject to revision.

The energy supplied to the gas engine is in the form of a combustible mixture of air and gas, the quality of which may vary considerably, also the head causing flow through the ports varies with every change in load, if it is a throttling engine.

In the four-stroke-cycle gas engine, the fuel mixture is made to flow into the cylinder by lowering the pressure in the cylinder below that of the atmosphere during the suction stroke, thus creating a difference of pressure sufficient to force in the charge.

The absolute pressure in the cylinder depends on the quantity of mixture entering the cylinder during the suction stroke. The amount of charge necessary in the cylinder depends on the load the engine is carrying, and therefore it is evident that a different amount is required for every change in load. Hence the absolute pressure in the cylinder during the suction stroke will be different for every different load, and the resulting pressure head causing the mixture to flow into the cylinder will be different.

This point can be most easily understood by neglecting temperature changes occurring during the suction stroke and assuming that the volumetric efficiency is merely a function of the difference between suction and atmospheric pressures. Since a light load calls for a small charge, it must correspond to a low volumetric efficiency. The low volumetric efficiency is always accompanied by a low suction pressure, due to the throttling at the valve, and therefore we have the peculiar condition that the greatest difference in pressure is available to cause flow when the least amount of mixture is required.

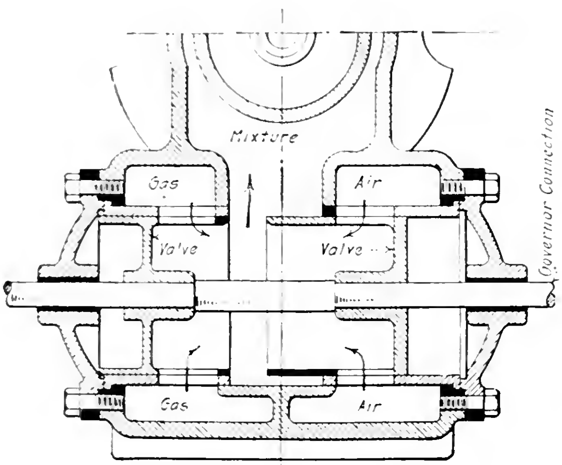

Fig. 1 Section Through Throttle Valve of a Horizontal Double-Acting Gas Engine

The result of this change in absolute pressure in the cylinder is such that when an engine is operating at, say, three-quarter load, with an apparent volumetric efficiency of about 67 per cent, and a change in load occurs which demands a volumetric efficiency of 77 per cent, it will require a much larger port area to give this increase of 10 per cent in volumetric efficiency at the heavy load than it would if the increase were from 30 per cent to 40 per cent. The reason being that, in the first case, the head causing flow through the ports will be about 3.5 lb. per sq. in., while in the second case it will be about 7.5 lb. per sq. in.

On account of the greater head causing the charge to flow into the cylinder at light loads, it requires a very small change in port area for a considerable change in load. Therefore, any system of connecting up the governor to the throttle valve which gives equal changes in port area for equal changes in the governor speed, will make the regulation of the engine very sensitive at light loads and too slow at heavy loads.

Data and Results from Test

The test described below was made to find out as near as possible (1) the conditions under which the fuel mixture enters a gas-engine cylinder, and (2) the relation of port area to horsepower and its influence on the regulation of the engine.

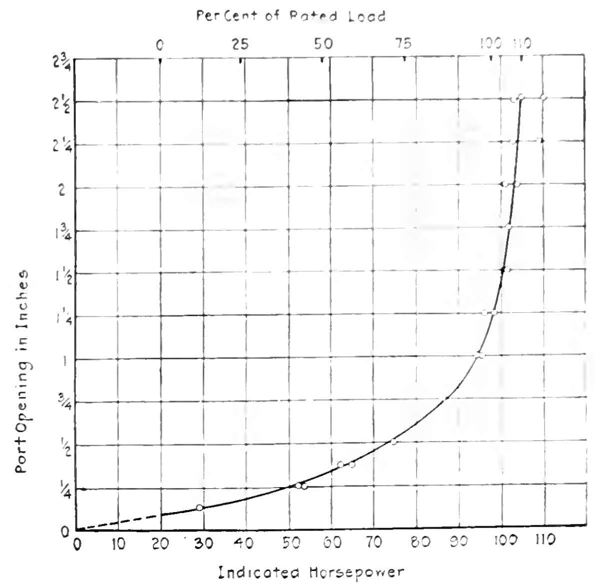

Fig. 2 Relation Between Indicated Horsepower and Port Opening

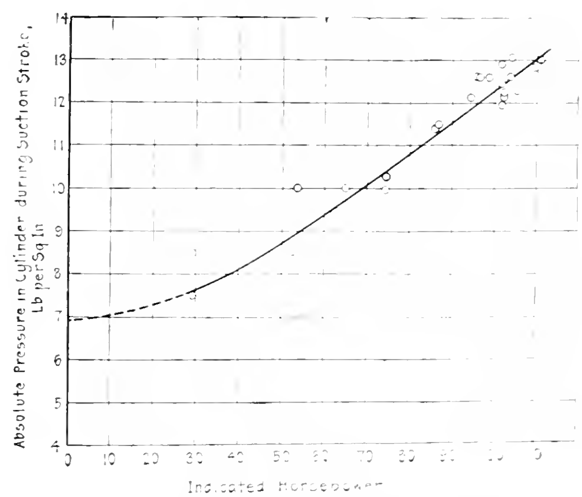

Fig. 3 Relation Between Indicated Horsepower and Pressure in Cylinder During Suction Stroke

Method of Making the Test. The engine tested was a [illegible] × 24-in. horizontal double-acting tandem engine operating on natural gas. The test was made in the following manner: The throttle valve on the head end of No. 1 cylinder was disconnected from the governor and operated by hand, while the other three valves, under the control of the governor, took care of the load on the engine. The throttle valve shown in Fig. 1 is cylindrical, with six rectangular ports cut around the periphery which mate with similar ports cut in a surrounding sleeve when the valve rotates. The throttle valve is made to

opened and closed in unison with the poppet inlet valve and is moved longitudinally by the governor to effect regulation. The travel of the valve was 2.5 in., and fifteen different settings were made, varying from closed to wide open. Two sets of indicator cards were taken for each setting, one for indicated horsepower and the other for suction, two or more cards for each set being taken for every position of the valve. From data obtained from these cards, curves were plotted, respectively, as follow:

Indicated horsepower
- against port opening
- against absolute pressure in cylinder during suction stroke
- against apparent volumetric efficiency

Port opening
- against apparent volumetric efficiency
- against absolute pressure in cylinder during suction stroke

Apparent volumetric efficiency
- against absolute pressure in cylinder during suction stroke.

If the machine friction is assumed constant for all loads, which is very nearly true, the delivered horsepower (d.hp.)

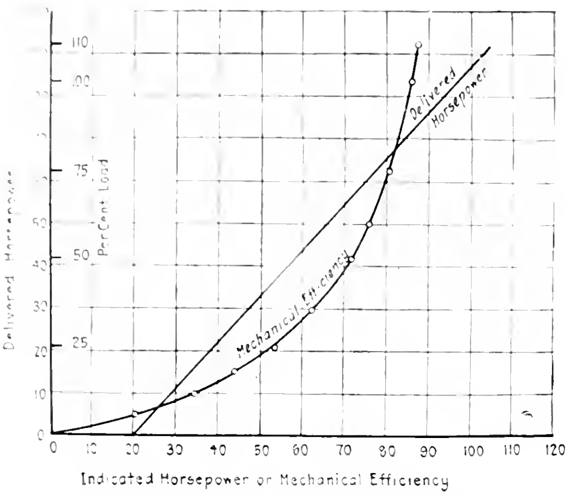

FIG. 4 RELATION BETWEEN DELIVERED HORSEPOWER AND MECHANICAL EFFICIENCY

for any load can be determined from the indicated horsepower by subtracting the loss due to the suction stroke, as measured by the suction card, and the loss due to the machine friction.

The d.hp. for several valves of i.hp. was found in the above manner, and from the results the mechanical efficiency was calculated. The values for i.hp., d.hp. and mechanical efficiency are given in the curves in Fig. 4.

Fig. 5 shows the relation between port area and d.hp. The data for this curve were obtained as follows: Delivered horsepower corresponding to any given i.hp. was taken from Fig. 4. The port openings as plotted in Fig. 2 are linear dimensions, the ports being rectangular in shape, $2\frac{1}{2}$ in. long by $1\frac{1}{2}$ in. wide.

The mixing valve was rigidly connected to the inlet valve and opened and closed in unison with it. The cam arrangement was designed to give a valve-opening curve approximating the sine curve, with the maximum port width (H) $1\frac{1}{2}$ in.

Hence the port area under these conditions is L x H x 0.637. The port opening or length L of port for full load is 1.15 in., as shown in Fig. 2. Therefore, the port area is 1.15 x 1.5 x 0.637 = 1.1 sq. in. for each port and for six ports it is 6.6 sq. in. Port areas for one-quarter, one-half, three-quarter and full load were found in this way and plotted against delivered horsepower, giving Fig. 5.

From Fig. 5 it can be seen that when the engine is operating near the rated-load point, it takes a large change in port area to effect a small change in the work developed by the machine, while at light loads a very small change in port area makes considerable change in the work done by the engine. The reason for this condition can be found by studying Fig. 3, from which it is seen that when the engine is operating at, say, full load, the absolute pressure in the cylinder during the suction stroke is high, being 12.1 lb. per sq. in. absolute or 2.1 lb. per sq. in. below the pressure of the atmosphere, while at one-quarter load the absolute pressure in the cylinder is 8 lb. per sq. in. or 6.2 lb. per sq. in. below the pressure of the atmosphere. The amount the cylinder pressure is below atmosphere pressure is the head available to force the charge into the cylinder, hence the peculiar conditions noted above exist, that when the engine is operating at full load and requiring a large amount of charge, the pressure head to produce flow into the cylinder is small, and when the engine is operating at light load and requires a small amount of charge, a much larger pressure head is available to produce flow through the ports.

From the above discussion and Fig. 5, it is evident that port area does not increase directly as the delivered horsepower increases, therefore, to get the same degree of regulation throughout the full range of load, some compensating device should be introduced between the governor and the throttle valve to take care of this condition. From Fig. 5 and the characteristic curve of the governor to be used, a mechanism can be designed which will give equal changes in load for equal movements of governor collar. This would seem to be a more desirable condition for good operation.

THEORETICAL DEVELOPMENT—OUTLINE OF METHOD

It has been found from tests that the total heat consumption of an engine follows a straight line very closely when plotted against delivered horsepower, and by assuming a reasonable value for the B.t.u. per d.hp-hr. for two points, say full load and half load, the total-heat curve can be drawn. From this curve with the heating value of the gas and the ratio of air to gas known, the cubic feet of mixture required for any fractional load can be determined. This amount of mixture, which must enter the cylinder, occupies a certain volume under atmospheric conditions. At the end of the suction stroke it occupies the greater part of the piston displacement but is under some lower pressure p_2, which can be determined by the relation $p_1v_1^n = p_2v_2^n$, providing the proper value of n be known.

From analyzing a great many low-spring indicator cards taken from throttling engines, it has been found that the absolute pressure in the cylinder during the suction stroke remains nearly constant throughout the greater part of the stroke, except for light loads. For the purpose of this discussion, it can be assumed to remain constant without serious error and will be the pressure p_2 of the charge when occupying the new volume as found from the equation above. The difference between the absolute pressure in the cylinder during the suction stroke and the pressure outside the cylinder is the head causing the charge to flow through the ports.

Knowing the amount of mixture required and the head producing flow, the area of the port necessary to pass the given amount of charge can be determined. In the above manner,

the amount of mixture required for any given load and the port area necessary to pass this charge can be determined, thus giving a relation between power and port area.

[The author here proceeds to apply the method outlined to the engine tested, which ran at 180 r.p.m. on natural gas of

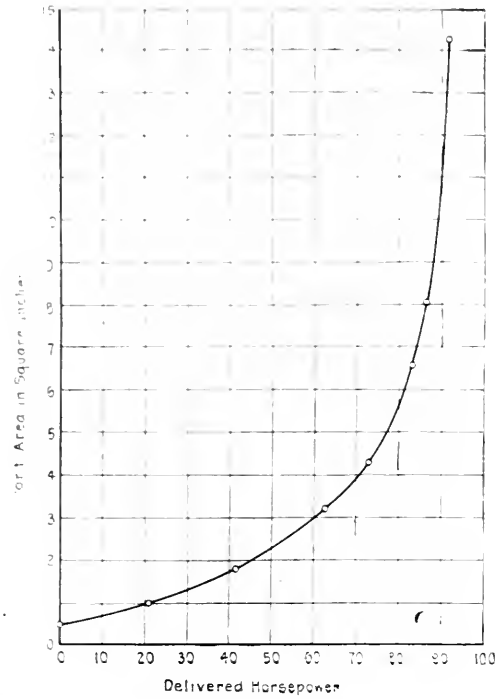

FIG. 5 RELATION BETWEEN DELIVERED HORSEPOWER AND PORT AREA

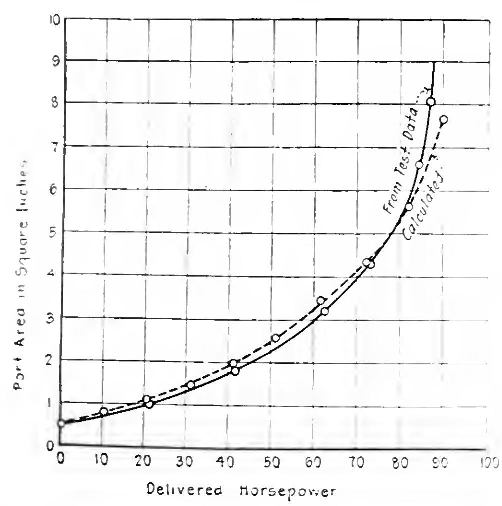

FIG. 6 RELATION BETWEEN DELIVERED HORSEPOWER AND PORT AREA FROM TEST AND CALCULATIONS

about 950 B.t.u. per cu. ft. He employs a value of 0.85 for n in the equation $p_1v_1^n = p_2v_2^n$, and shows in an appendix why this value is chosen.

He also derives an empirical equation for the port area necessary to pass a given amount of charge, which gives results agreeing closely with those obtained from test data. See Fig. 6.]

CONCLUSIONS

The work described has been done to find out as nearly as possible the conditions under which the charge enters the cylinder of a throttling gas engine, and to design a method of supplying the required amount of charge for any load that will tend to make the engine regulate with the same degree of sensitiveness throughout the full range of load. In Fig. 6 there are two curves showing the relation between delivered horsepower (d.hp.) and port area; one is based on test data and the other is plotted from calculated data for the same engine. From these curves and the characteristic curve of the governor to be used, the relation between the travel of the governor collar and port area can be determined and a governing mechanism designed which will give equal changes in load for equal movements of the governor collar. Another way of obtaining the same result would be to shape the ports in such a manner that equal changes in governor-collar travel would give equal movements to the valve, but at the same time give the proper port area for equal changes in power delivered. It is possible that for other fuels and types of engines the constants used in working out the above problem may differ slightly, but it is believed that the method can be applied to any case with satisfactory results.

Metals for Coinage. War conditions, which have been responsible for the replacement of gold coinage by paper money, have also had their effect on the metals used for coins of the smaller denominations. Aluminum money has been used by the Chambers of Commerce of several French towns, and Austria, following the example of Germany, has adopted iron money. The problem of protecting the iron disks from rust has been solved by superimposing a slight layer of zinc. The disks, with some zinc powder, are placed in a vessel and heated for a certain time at a temperature somewhat below the melting point of zinc. A surface is thus formed which not only preserves the pieces from rust, but also enables the die to be impressed without cracking the surface of the metal. The zinc-plated iron money hardly differs in aspect or weight from that formed of nickel.—*Ironmonger*, March 24, 1917.

X-Rays and Metals. Some authorities hold the view that X-rays are destined to play an important part in research of steel and other metals, especially in investigations on the crystalline structure. The perfect crystal has a definite internal geometrical form and a definite atomic symmetry, but the latter is beyond the range of the microscope. The more powerful X-rays may, however, enable the metallurgist to determine the atomic structure of his metals. Students of the new method predict that it will throw light on some phases in metallurgy of which nothing is known at present. The commercial value of the researches remains, of course, to be proved; but the progress of the work is being followed with deep interest in various countries. Professor Bragg, a pioneer in this work, in a recent address on the subject at Sheffield, England, remarked that chemistry told the metallurgist what were the constituents of his metals, but thought X-rays were going to help him to find and study the atoms of the substances, and the actual arrangement of these and the distances at which they lay apart were of considerable importance, but had hitherto been beyond human vision. The X-rays had made it possible to see the architecture of a number of substances. Iron and steel presented difficulties, but there was a good prospect of getting useful information about them before long. The work was going ahead in the United States, and he had received from American physicists particulars of interesting results obtained in respect to iron and steel crystals. —*Ironmonger*, March 24, 1917.

MISCELLANEOUS PAPERS

One session of the Spring Meeting will be devoted to the discussion of miscellaneous papers upon the subjects of tests of uniflow steam traction engines, relation of efficiency to capacity in the boiler room, radiation error in measuring temperature of gases, development of scientific methods of management in a manufacturing plant, and disk wheel stress determination. All of these papers are printed below.

TESTS OF UNIFLOW STEAM TRACTION ENGINES

By F. W. MARQUIS, COLUMBUS, O.

Member of the Society

At first thought it seems strange to find refinements such as the uniflow cylinder and the superheater in connection with traction engines; but when it is remembered that traction engines are used extensively in certain districts (notably the northwestern part of the United States) where fuel is very expensive and water has to be hauled many miles, the reason for taking advantage of every means for reducing coal and water consumption becomes apparent.

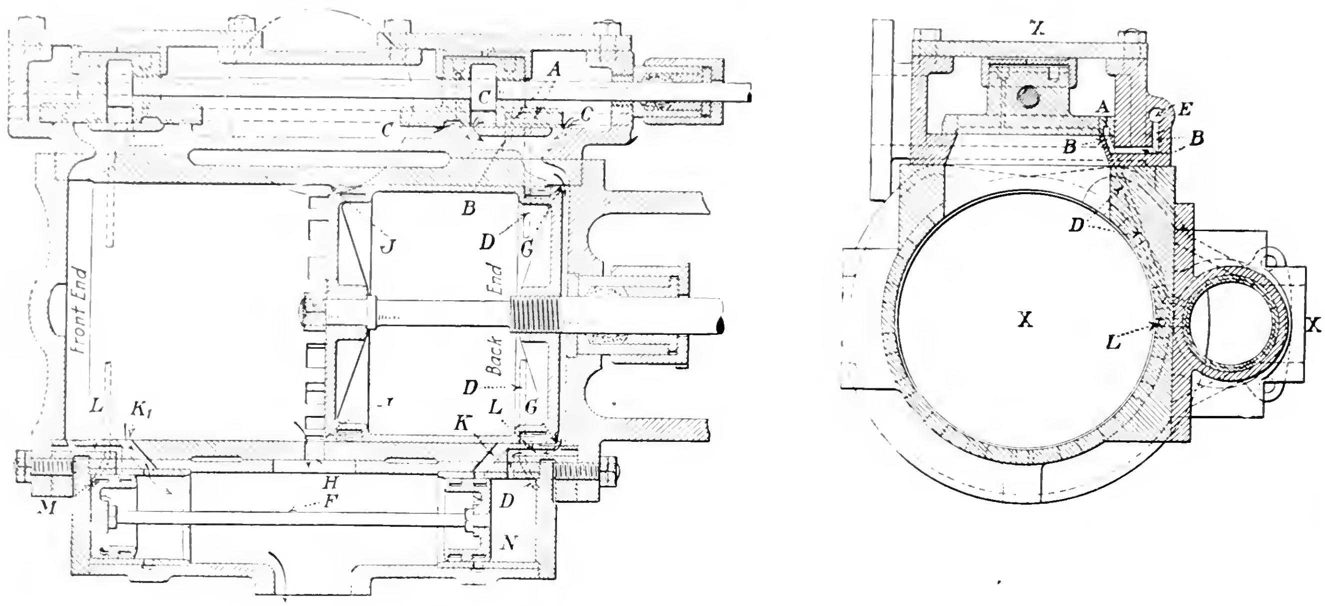
It was, therefore, with a great deal of interest, in the spring of 1915 and again in the spring of 1916, that tests of Baker uniflow traction engines were undertaken as thesis work by members of the senior class of the Mechanical Engineering Department of The Ohio State University.

The engine tested in 1916 was almost identical with that tested in 1915, except that in 1916 the boiler was supplied with a smokebox-type superheater. The piston displacement of the engine tested in 1916 was $8\frac{1}{2}$ per cent larger than that of the engine tested in 1915 and the water heating surface of the boiler $21\frac{1}{2}$ per cent larger. Both machines were made by the A. D. Baker Company, of Swanton, Ohio, and in accordance with their standard designs, except for the uniflow cylinder and the superheater, which were then in process of development.

The principal dimensions of both engines are given in Table 1. Besides the uniflow cylinder and the superheater, the feature of particular interest is the valve gear, which deserves special attention and will later be described.

Figs. 1 and 2 show cross-sections through the cylinder and valves. There are triple-ported admission valves, and an auxiliary exhaust valve which causes the compression to begin late in the stroke.

The operation of the valves can best be explained by following their movement as the piston moves through one stroke. Suppose the piston to be moving towards the right and nearing the end of its stroke; that is, a little to the left of its position in Fig. 1. The admission valves (top of figure) will then be a little to the right of the position shown, and moving towards



FIGS. 1 AND 2 BAKER UNIFLOW CYLINDER AND VALVES

the left. The auxiliary exhaust valve F (bottom of figure) will be at the extreme right end of its travel, and stationary.

When the edge J of the piston uncovers the ports at the center of the cylinder, exhaust commences. About the same time the cavity A in the admission valve uncovers the port at the end of passage B and allows live steam to flow from E (Fig. 2), through passage B, cavity A and passage D into chamber N at the end of auxiliary exhaust valve F. This causes valve F to move to the extreme left of its travel, closing the auxiliary exhaust port K and opening the auxiliary exhaust port K_1. Exhaust is then taking place both through the main exhaust ports and through auxiliary exhaust port K_1. An instant after the auxiliary exhaust valve moves and just before the piston reaches the end of its stroke, admission takes place through the three ports C.

As the piston starts on the return stroke towards the left, exhaust takes place through the main exhaust ports until, early in the return stroke, they are covered by the piston. The

For presentation at the Spring Meeting, Cincinnati, Ohio, May 21 to 24, 1917, of The American Society of Mechanical Engineers. Total water heating surface	146.8	182 7
Superheater heating surface	...	47

steam still continues to exhaust through auxiliary exhaust port K, until the piston covers this port, late in the stroke, when compression starts. Meanwhile live steam has been admitted on the other side of the piston until the admission valve has returned and cut-off has occurred. After cut-off and during expansion, the live steam in chamber N, at the head of the auxiliary exhaust valve, is free to expand through passage L and do work on the piston. This passage L enters the auxiliary exhaust valve chamber at such a point that when the valve is thrown some steam is trapped between it and the end of the valve chamber, thus cushioning it and preventing pounding.

The admission valves are driven by a Baker valve gear, which is very similar to the Baker locomotive gear. It is a single-eccentric variable cut-off and reversing gear which maintains equal leads for all cut-offs and in both directions of running. The complete paper illustrates and describes the gear.

The boiler used in the 1916 tests was fitted with a smokebox-type superheater, consisting of a vertical cast-iron header, into which tubes are inserted, as shown in Fig. 3. Steam enters through pipe A, Fig. 4, which leads from the steam dome and passes to the front section of the header. It then passes back through the ½-in. pipes and forward through the 1½-in. pipes into the back section of the header. Thence it passes through B to the steam chest.

METHOD OF PROCEDURE IN TESTING

The tests were conducted in the Mechanical Engineering Laboratory of The Ohio State University and in general the methods recommended in the A.S.M.E. Power Test Code were followed. All coal fired was weighed, sampled, analyzed and the calorific value determined. The feed water was weighed and correction made for injector overflow and other wastes. The quality of steam was taken with a Barrus throttling calorimeter, the sampling pipe being located in the path of the steam as it left the steam dome. Smokebox temperatures were determined with a thermocouple and the smokebox gases were sampled continuously, and analyzed with an Orsat apparatus. Indicated and brake horsepower and revolutions per minute were all carefully determined. All instruments were calibrated and corrections applied where necessary.

The tests were run with the throttle valve wide open, and in general it was attempted to maintain the speed constant at 250 r.p.m. During the preliminary running preceding each test the brake load was adjusted so that the desired speed was obtained

Fig. 3 Superheater Removed from Boiler

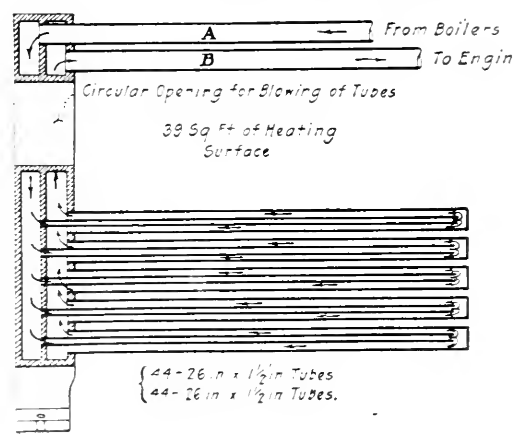

Fig. 4 Diagram of Superheater

when the throttle valve was wide open. During each run all conditions were maintained as constant as possible.

First Series. The 1915 series consisted of 17 tests with various boiler pressures ranging from 125 lb. gage to 175 lb. gage, and various cut-offs ranging from 6 to 49 per cent. Saturated steam was used throughout this series, and the approximate speed was 250 r.p.m. in all tests.

Second Series. The 1916 series consisted of 17 tests, 13 at 180 lb. gage and 4 at 160 lb. gage. Nine of the former were with superheated steam, and 4 with saturated steam. Superheated steam was used for the four latter tests. The cut-off in this series varied from 16 to 75 per cent. The approximate speed was 240 r.p.m., with the exception of three short runs

[illegible]

[illegible] performance, with the [illegible] performance are tabulated in the report. Many [illegible] results are also presented graphically [illegible] Figs. [illegible]

In Fig. [illegible] sample sets of indicator diagrams, one with [illegible] and the other with a much later cut off [illegible] lack of wire-drawing during admission, and [illegible] for a slide valve engine running at such [illegible] r.p.m. The drop in the early part of the expansion [illegible] diagrams with an early cut off, and that [illegible] of the diagrams with the later cut off, is caused [illegible] steam flowing into the auxiliary exhaust-valve chamber at the instant the piston uncovers the port leading to this chamber.

Reference to Fig. 5 shows that the highest steam consumption was just under 29 lb., which occurred at 125 lb. boiler

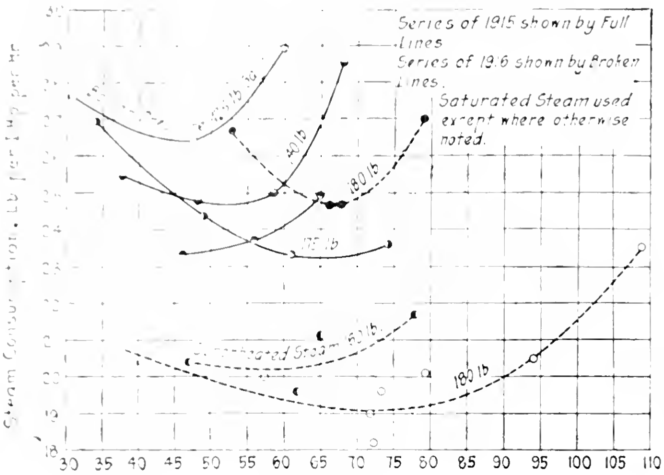

FIG. 5 CURVES SHOWING RELATION BETWEEN STEAM CONSUMPTION AND INDICATED HORSEPOWER

pressure with saturated steam and at approximately 60 i.hp. The lowest was 18.2 lb. per i.hp-hr., in the series of 1916, with 180 lb. boiler pressure and 118 deg. superheat, at about 72 i.hp. Reference to the curve shows, however, that this point was abnormally low.

It seems reasonable to assume that the engine should be rated at approximately the point of best economy. On this basis the rating when operating under 125 lb. boiler pressure would be 45 i.hp. Tests were run from about 30 to about 60 i.hp. or from about 60 per cent to 130 per cent of this rated load, and over this range the variation in steam consumption was from approximately 29 to $26\frac{1}{2}$, or only about $2\frac{1}{2}$ lb.

It is interesting to note that the maximum power obtained was 108.7 i.hp. (102.8 b.hp.) which was obtained with 180 lb. boiler pressure and with 181 deg. fahr. superheat, and with a steam consumption of only 23.5 lb. per i.hp. per hour (24.5 lb. [illegible]). This becomes particularly interesting [illegible] remembered that the cylinder diameter and stroke [illegible] are only $9\frac{1}{4}$ in. and 10 in. respectively.

The curves of Fig. 6 show the relation between steam consumption and boiler pressure. As the boiler pressure increases, not only does the steam consumption decrease, but also the power at any cut off, and the power at which the lowest steam consumption occurs increases. It will be noticed that, with the exception of one point on this curve, the power of minimum steam consumption increases as the boiler pressure increases.

The curves of Fig. 7 show the relation between the pounds of coal used per brake horsepower per hour and the brake horsepower developed.

As a matter of interest from a comparative point of view,

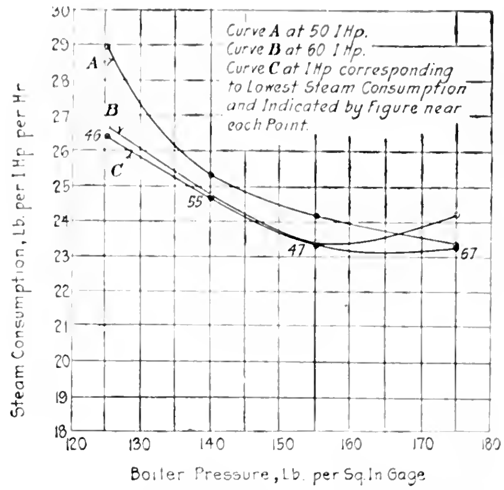

FIG. 6 CURVES SHOWING RELATION BETWEEN STEAM CONSUMPTION AND BOILER PRESSURE, SERIES OF 1915

the steam-consumption curves of a number of the ordinary counterflow type of steam engines, both simple and compound, non-condensing and condensing, have been plotted on the same sheet with certain of the steam-consumption curves of the Baker uniflow engine. These curves are given in Fig. 9. In-

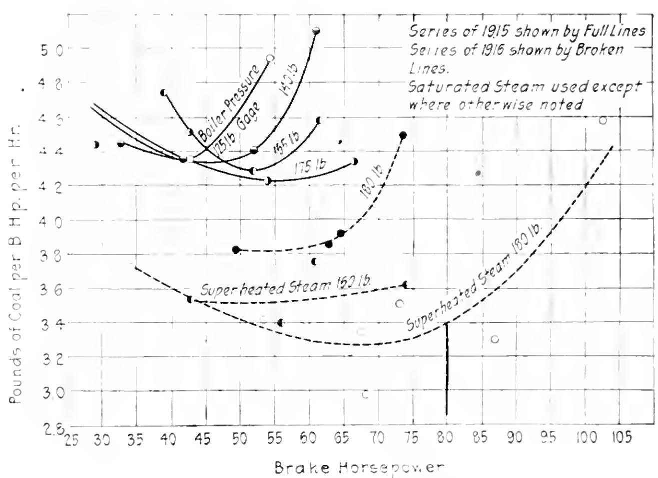

FIG. 7 CURVES SHOWING RELATION BETWEEN POUNDS OF COAL PER BRAKE HORSEPOWER PER HOUR AND BRAKE HORSEPOWER

formation concerning each of the engines whose steam-consumption curve is given in this figure will be found below.

Curve *A*. Simple, slide-valve engine, cylinder 8 in. by 12 in., initial steam pressure 130 lb. gage, non-condensing, and at 200 r.p.m.

Curve *B*. Simple, slide-valve engine, cylinder 9 in. by 12 in., initial steam pressure 140 lb. gage, non-condensing, and at 290 r.p.m.

Curve *C*. Simple, slide-valve engine, cylinder 15 in. by 14 in., initial steam pressure 115 lb. gage, non-condensing, and at 225 r.p.m.

Curve *D*. Same engine as in case of curve *C*, but operating condensing.

Curve *E*. Cross-compound, slide-valve engine, cylinders 7 in. and 13 in. by 10 in., initial steam pressure 150 lb. gage, non-condensing, and at 310 r.p.m.

Curve *F*. Same engine as in case of curve *E*, but operating condensing.

Curve *H*. Tandem compound, slide-valve engine, cylinders 8¼ in. and 13¼ in. by 12 in., initial steam pressure 115 lb. gage, condensing, and at 280 r.p.m.

Curve *G*. Simple uniflow engine, cylinder 8¾ in. by 10¼ in., initial steam pressure 125 lb. gage, non-condensing, and at 250 r.p.m.

Curve *I*. Same engine as in case of curve *G*, but with 175 lb. gage boiler pressure.

Curve *K*. Simple uniflow engine, cylinder 9¼ in. by 10 in., initial steam pressure 180 lb. gage, superheat approximately 130 deg. fahr. non-condensing, and at approximately 240 r.p.m.

It will be seen that the uniflow-engine curves selected are those representing the poorest and the best results obtained with saturated steam, and the best results obtained with superheated steam.

A study of this set of curves (Fig. 9) shows that the poorest results obtained with the uniflow engine, namely, those of curve *G*, obtained with saturated steam at 125 lb. pressure, are better than the best results obtained with any of the simple engines, even when operating condensing, and almost the same as those obtained with the compound non-condensing engine shown by curve *E*. The steam consumption of the uniflow engine at 175 lb. pressure with saturated steam running non-condensing is lower than that obtained with the compound non-condensing

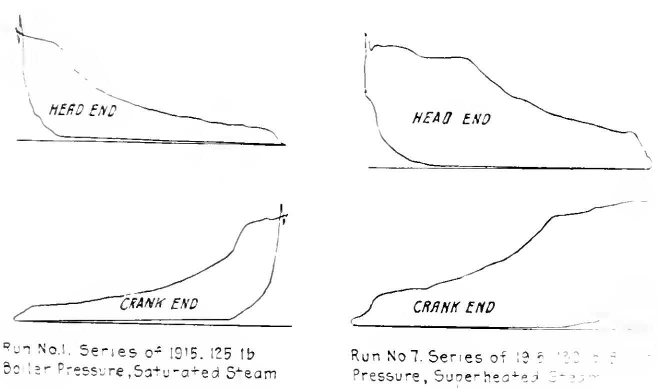

Fig. 8 Sample Indicator Diagrams

engine at 150 lb. pressure shown by curve *E*. Also the steam consumption of the uniflow engine with 180 lb. steam pressure and 130 deg. superheat was lower than that of the compound condensing engine with 150 lb. steam pressure shown by curve *F*.

Thus it is seen that on the basis of the results of the tests and of the information presented by Fig. 9, which is thought to represent fairly the average practice for small simple and compound engines of the older or counterflow type, the simple uniflow engine operating with saturated steam and non-condensing is able to surpass in economy of steam consumption the compound counterflow engine when operating under similar conditions. Also that the simple uniflow engine operating non condensing but with superheated steam will have approximately the same, or slightly less, steam consumption than the compound counterflow engine operating condensing but with saturated steam.

On the bases of these conclusions, it seems probable that the simple uniflow engine will prove a serious competitor of the compound counterflow type, since it is not only more economical in its use of steam, but also simpler in construction, and probably on that account lower in first cost.

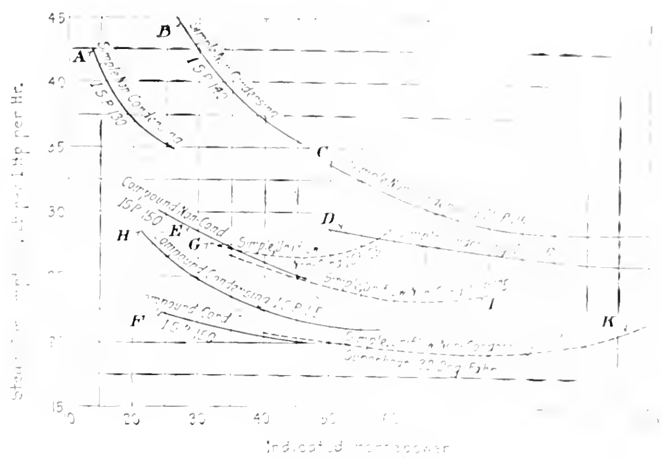

Fig. 9 Relative Steam Consumption of Baker Uniflow Engines and Counter-flow Engines

RELATION OF EFFICIENCY TO CAPACITY IN THE BOILER ROOM

By VICTOR B. PHILLIPS, CLEVELAND, OHIO

There are two ways in which the cost of producing steam may be reduced. They are efficient operation and the attainment of high capacity from equipment. Table 1 gives the typical figures for the various elements of cost entering into the production of steam, according to the accounts of the Cleveland Railway Company[1] for the year 1914. The numbers shown in parentheses refer to the accounting system prescribed by the Interstate Commerce Commission. This table shows the predominating importance of fuel and fixed charges, and hence the importance of both efficiency and capacity and their interrelation.

To the end of establishing the operating conditions giving maximum efficiency for a wide range of capacities, the writer has made an extensive series of tests for the Cleveland Railway Company. The tests were conducted under widely different operating conditions in order to bring out clearly the importance of the several variables and also to throw light on questions of design. In Table 2 is a condensed summary of the data obtained, together with some notes as to procedure.

GENERAL DESCRIPTION OF TESTS

Equipment (see Fig. 1). Taylor six-retort stoker with extension grate. Babcock & Wilcox boiler, 5120 sq. ft. heating surface.

[1] Cleveland Railway Company.

For presentation at the Spring Meeting, Cincinnati, Ohio, May 21 to 24, 1917, of The American Society of Mechanical Engineers. The paper is here printed in abstract form, and pamphlet copies of the complete paper may be obtained by members gratis upon aplication. All papers are subject to revision.

[illegible]. Eight-inch [illegible] provided [illegible] under test conditions [illegible] several days before tests [illegible] which referred [illegible] operation chart. Readings taken [illegible] minute.

Personnel. In addition to regular operating fireman and helper, personnel included six men all of whom had become thoroughly familiar with their duties through previous tests.

TABLE 1 COST FACTORS IN STEAM PRODUCTION

Cleveland Railway Company

		Per cent of total cost	
[illegible]	Fuel	50.1	50.1
[illegible]	Water	3.4	
[illegible]	Oil and miscellaneous supplies	0.4	
[illegible]	Maintenance	6.4	
[illegible]	Employees	9.6	9.6
[illegible]	Depreciation, $1\frac{1}{2}$ per cent on investment	11.3	11.3
To these must be added interest, taxes and insurance, $7\frac{1}{2}$ per cent on investment.		18.8	18.8
Total cost of producing steam		100.0	
Fuel and fixed charges			89.8

Coal and Water. Both items were weighed on newly calibrated scales. Coal sample taken from every wheelbarrow and placed in covered receptacle.

Air Supply. Air delivered to furnace from fan was measured by pitot tubes placed in air ducts and preceded by baffles to create parallel flow; permanently located pitot tubes were calibrated by complete traverses in two directions through the pipe and results checked with an anemometer and by the calorimetric method. Pressure and draft gages checked.

Temperatures. Obtained by thermo-electric pyrometers, checked by manufacturer before and after tests.

Gas Analysis. Conducted by chemist. Continuous samples taken during consecutive half-hour periods. Sampling tube inserted at top of first pass; lined with hard glass tubing and open at end only; moved in and out so as to get representative sample. Analysis made with Orsat apparatus.

Regulation of Fire. Fuel bed was kept uniform and constant in thickness, by very close and frequent observation on the part of three different men, all experienced firemen.

Ash Analysis. All ash was spread out and crushed to about $1\frac{1}{2}$ in. on a large concrete floor and dried before weighing. The sample for analysis was taken by dividing the ash, when evenly spread out, into a large number of squares, and then moving away alternate squares until a comparatively small sample for grinding was obtained. During this reduction process the ash was continually mixed by turning it over. The samples were analyzed for moisture, combustible and in some cases for sulphur or volatile constituent.

SCOPE OF PAPER

This paper proposes for discussion the systematic treatment of the steam boiler in relation to the two fundamental variables—efficiency and capacity. The efficiency which obtains at a given capacity depends upon the interrelation of a large number of variable factors of operation. It is essential that these factors be systematically conceived, and that in a given case some idea of their relative importance be formed. Recent stoker developments to the end of greater flexibility have introduced a large number of adjustments over which intelligent control must be exercised. This merely goes to illustrate the

TABLE 2 SUMMARY OF TEST DATA

Cleveland Railway Company

Test No.	1	2	3	4	5	6	7	8	9
1 Fuel bed thickness		Thin			Medium			Thick	
2 Horsepower output of boiler, (steam pressure 150 lb. gage)	452	661	895	500	736	923	504	718	902

[1] Flue gas per pound of coal, taken from items 3 and 8 to which is added 0.8 pound for gasified coal.

[2] One sample for Tests 7 and 8.

[3] The CO analyses, especially for the overload tests (Nos. 3, 6 and 9), were probably somewhat in error due to taking of sample at top of first pass where gases were not thoroughly mixed. During Test 9 both the oxygen and CO content of the flue gas taken at this same point were high. There was also a marked amount of incandescent matter in the flue gas. It is therefore probable that considerable combustion of CO occurred in the second and last passes. This is indicated by the fact that the items of the heat balance for this Test 9 added up to a little more than 100 per cent.

necessity of less prejudice and more rational procedure in boiler-room design and operation.

In what follows, a classification of the variables of operation will be outlined, and a system of testing discussed, whereby their interrelation may be established. The results of the tests already quoted, which were made in accordance with this system, will be used by way of illustration. All mathematical treatment and detail of procedure are listed in an appendix. It should be pointed out at the outset that the test data used are necessarily limited, and in some respects incomplete. Yet perhaps they will serve as a concrete basis or example in outlining the method of treatment.

ELEMENTS OF BOILER UNIT AND BASIC FACTORS WHICH GOVERN ITS PERFORMANCE

The steam-boiler unit is considered here in relation to each of its two elements, the *furnace* or heat liberator and the *boiler* or heat absorber.

The furnace is a means whereby the chemical energy of coal or other fuel is transformed into sensible-heat energy. The function of the furnace is chemical reaction between the combustible fuel and the oxygen of air. As such, it is governed

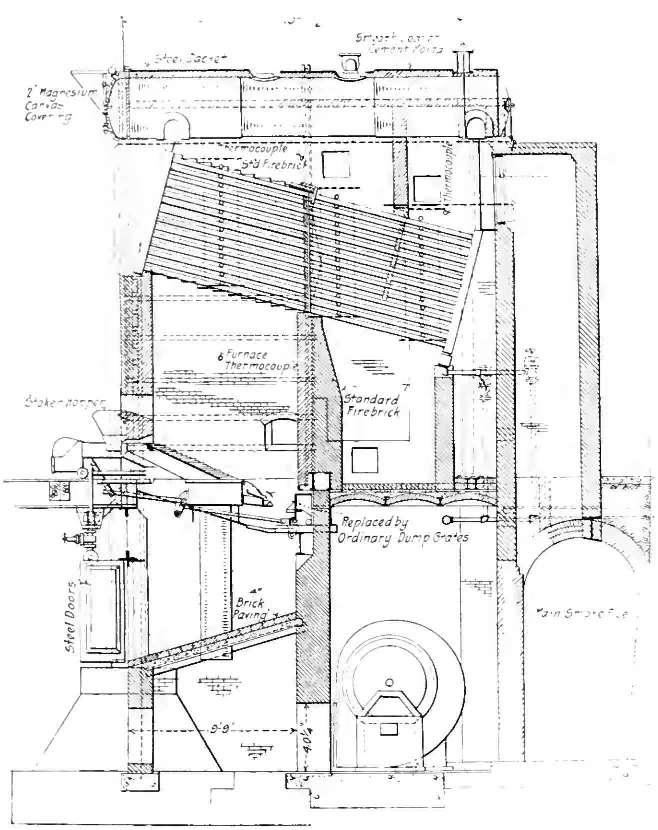

Fig. 1 Sectional View of Boiler Unit of the Cleveland Railway Company

by the three factors, (1) amount of air, (2) degree of air mixture and (3) time. These three factors together govern the rate of combustion, the completeness of combustion and the resultant temperature of combustion; in a word, they completely determine the nature of combustion.

The boiler is a means whereby the heat liberated in the furnace is absorbed and transferred to the water. Its function is heat transmission and it is governed by the laws expressing the several modes of heat transmission,—conduction, convection and radiation. It is evident that the factors which govern combustion likewise govern very largely the heat transmission of the boiler, by the regulation of temperature and amount of gas. Hence, it follows that in the end the performance of the entire boiler unit may be expressed in terms of a number of factors over which the fireman either does or should be able to exercise proper control.

Before proceeding with the separate discussions of the two elements of the boiler unit, it is necessary to define clearly the lines of separation of the furnace and the boiler. It is desirable so to define furnace efficiency and boiler efficiency that

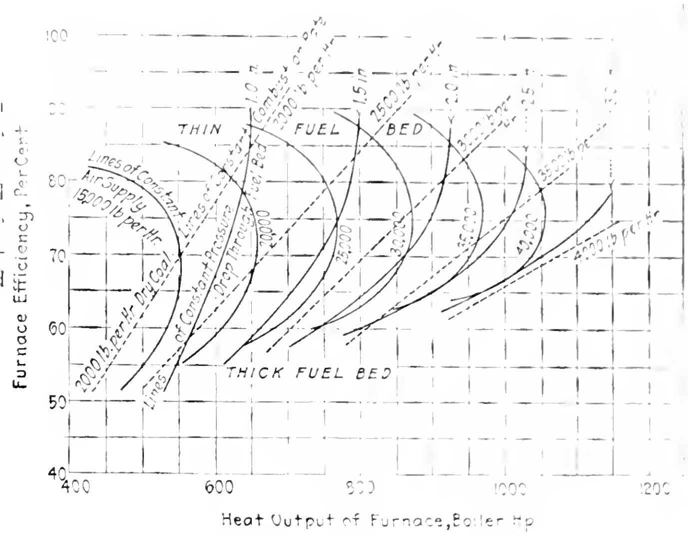

Fig. 2 Furnace-Operation Chart. Taylor Six-retort Stoker with Extension Grate

their product will be the overall efficiency of the unit. To this end boiler efficiency is taken as the ratio of heat absorbed to the heat available for absorption, *i.e.*,

$$E_B = \frac{\text{heat in steam}}{\text{heat in steam and sensible heat in flue gas}}$$

Furnace efficiency is defined as the ratio of heat available for absorption by the boiler to the heat in the coal, *i.e.*,

$$E_F = \frac{\text{heat in steam and sensible heat in flue gas}}{\text{heat in coal}}$$

and

$$E\,(\text{overall efficiency}) = E_F \times E_B$$

This method arbitrarily charges against the furnace all losses through the setting, such as radiation and leakage. Most of these losses do occur in the setting around the furnace and so this arbitrary classification is reasonable. It also charges against the furnace the loss in latent heat in the vapor of the discharged flue gases.

THE FURNACE

The ideal furnace for any form of fuel is one in which the three factors of combustion mentioned above,—amount and admixture of air, and time for completion of combustion, may be regulated independently. This furnace would have wide limits of efficient operation wherein it would be possible to attain at once both efficiency and capacity. Unfortunately the present status of the art, particularly in regard to coal-burning furnaces, falls far below this ideal.

The most important methods of firing coal employ the

[illegible] the underfeed and overfeed gravity stokers it [illegible] time of transit of coal decreases with [illegible] of load and forced-draft independent regulation, [illegible] it is impossible to regulate independently the amount and admixture of air. The [illegible] supply are controlled together by the amount of draft or pressure and by the condition of the fuel bed. These several inflexibilities are inherent in the present state of the art. They are serious disadvantages which can be [illegible], however, by introducing in other ways a large degree of flexibility.

Since regulation [illegible] by regulation of grate surface seems to be impracticable, the problem of furnace operation becomes simply the *problem of the air supply*, not merely [illegible] as a whole, but in its several parts separately. That flexibility of air supply will to some extent compensate for inflexibility in time of transit, may be illustrated by any of the underfeed gravity stokers. The grate areas of these stokers have been proportioned to give the proper time element for rated capacity.

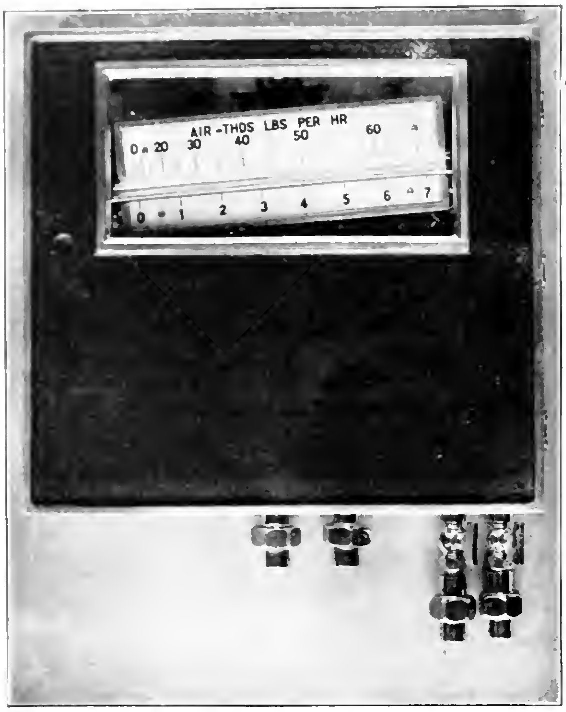

Fig. 3 Air Meter

For example, take the case of the Taylor stoker used in the equipment of the Cleveland Railway Company's plant which the writer tested. When the capacity is increased, the air supply on the lower or coking grates cannot be increased enough to burn the coal as fast as it is received from the upper grates. The result is a piling up of coke and ash on the dump and extension grates causing not only a large loss from carbon monoxide and coke to the ash pit, but perhaps serious clinker difficulties. A variable grate surface would eliminate this trouble. It could, however, be largely mitigated by flexible and independent air control for this section of the fuel bed. This is discussed further in the Appendix.

FUNDAMENTAL FACTORS OF OPERATION OF THE FURNACE

The operating variables of the furnace are simply the variables governing air supply. They are (1) thickness of fuel bed, (2) condition of fuel bed, and (3) pressure drop through fuel bed. These variables may be regulated differently in different parts of the furnace, but they are in all events the fundamental factors involved. They determine efficiency and capacity. In order to operate a furnace properly, the interrelations between efficiency and capacity and the foregoing variables must be established.

The validity of this principle has not been generally realized. Instruments for the indication of certain variables have been extensively used. Yet, either the number of instruments or the amount of rational interpretation has been insufficient. It is only in very special and limited cases that efficiency or capacity is indicated by a single variable factor such as carbon dioxide, or flue temperature.

Having defined the fundamental factors of operation, it now remains to select means of indicating these quantities to the fireman. The means of indication necessarily vary for different types of stokers and furnaces. With a chain grate the thickness of fuel bed may be readily measured and adjusted, and its condition is for the most part uniform. The draft in the combustion chamber constitutes the pressure drop through the fuel bed. Thus the chain grate readily lends itself to this system, and it is a simple matter to determine by tests

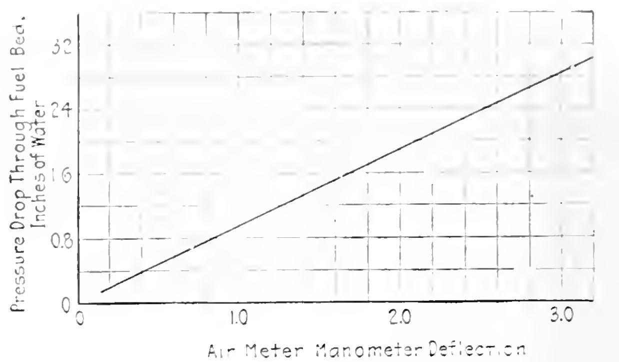

Fig. 4 Relation Between Pressure Drop Through Fuel Bed and Air Meter Manometer Deflection. Fuel Bed of Constant Thickness

the relation of furnace efficiency and capacity to the operating variables. In fact, the limits of expedient and efficient operation with the chain grate are not only narrow, but readily apparent. This is a salient feature of this type of stoker. On the other hand, the forced-draft underfeed stoker is not by any means so simple, and here intelligent control is not only effective but essential. In this case the thickness of fuel bed cannot be *directly* measured nor is its uniformity so much a matter of course.

The point of primary importance is the amount of air pushed through the fuel bed and the intimacy with which it is mixed with the volatile matter forming in the lower layers of green coal and the coke of the upper layers. Roughly speaking, this intimacy increases with the resistance to air flow. It is the condition and thickness of the fuel bed that determines both the amount and admixture of air. The pressure necessary to force up a certain quantity of air is both a simple and an effective indication of the mean condition and thickness of the fuel bed; in other words, an air-pressure gage and an air meter indicate the thickness of bed. In stokers of sufficient size to warrant the use of two air ducts, it is necessary to duplicate the air-measuring apparatus. By proper arrangement of the means of indication it now becomes

possible to gage the uniformity of the fuel bed by comparing the air indications to the two halves. Thus all the conditions governing air supply may be readily measured, and indicated to the fireman. In order that he may make proper use of these indications they must be related to the objects sought—efficiency and capacity.

As an illustration of the actual interrelating of the above indications, there is presented in Fig. 2 a chart showing graphically the results of the tests applying to the furnace.

It may be seen that this chart is a graphical representation of the principles outlined above. It shows how furnace capacity and efficiency are functions of extremely simple variables, and how any two of the variables fix conditions of operation. An analogy is a steam chart on which any two conditions, such as heat and pressure, or quality and temperature, determine a point from which the other corresponding conditions may be found. The chart brings out in conclusive manner the essential importance of the variables selected at the beginning of the discussion—thickness of fuel bed and pressure drop. So far as the furnace as a heat liberator is concerned, it establishes the conditions of maximum efficiency for each and every load.

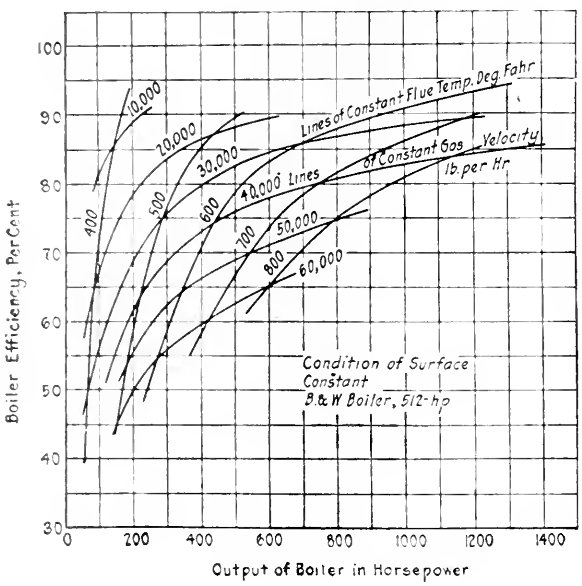

FIG. 5 THE BOILER AS A HEAT ABSORBER. BOILER-OPERATION CHART SHOWING INTERRELATION OF VARIABLES

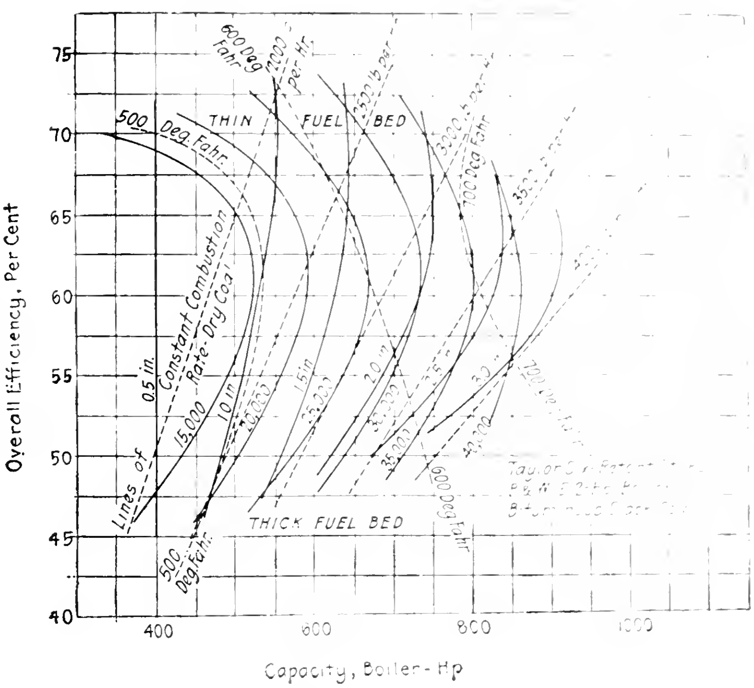

FIG. 6 OPERATIVE CHART, COMBINED BOILER UNIT

MEASUREMENT OF AIR SUPPLY

Of the instruments used by the writer in obtaining the results presented here, the apparatus for directly measuring the air supply, Fig. 3, merits perhaps a brief statement. It is quite possible to employ the pitot tube with close accuracy for measuring the air supply of forced-draft furnaces, and even where conditions are extremely unfavorable to obtain at least excellent relative results. The manometer used in connection with the pitot tube may be placed at a distance from the air duct, along with the other boiler instruments, without impairing its accuracy. When two manometers are necessary because of two air ducts the sloping tubes may be placed side by side and readings taken from a single scale. The only time that the liquid levels will not be side by side will be when the fuel bed is not uniform, a condition requiring immediate attention from the fireman. For example, a hole will cause a very marked difference in the two manometer level.

Another principle may be employed in connection with the form of air meter just described. The pitot tube manometers show deflections increasing as the square of the air velocities. Similarly, neglecting the relatively small amount of gas formed from the burning coal, the pressure drop through the fuel bed varies as the square of the air velocities. Hence, as is shown in Fig. 4, the relation between this pressure drop and the manometer deflection is a direct proportion. Utilizing this principle, another manometer tube[1] may be placed beside the other tubes for the measurement of pressure drop. By using liquids of the proper relative densities, or by introducing variation in the sectional area of the manometer, the levels can be set to move up and down together for the proper thickness of fuel bed; and a ready indication of amount of variation from the prescribed thickness is available. This last function is valuable in plants having short peak loads. The fireman may gage the amount by which he is building up his fuel preparatory to the short overload. Thus a single instrument has been made to indicate all the fundamental conditions of combustion—amount of air, pressure drop through the fuel bed, and thickness and uniformity of fuel bed.

THE BOILER

The performance of the boiler as an apparatus for absorbing heat is here analyzed in the complete paper along the same general lines as the furnace. The furnace produces heat which is available for absorption in the form of radiant energy and of hot gases, that is, the heat generated in the incandescent fuel bed is transmitted to the boiler surfaces by radiation and by convection. It is then transmitted from

[1] Not shown in Fig. 3 but exactly similar to the two tubes shown.

[illegible] to the inner surface, and to the water by conduction. The boiler involves, therefore, all three modes of heat transmission, and the variables of operation are those determining the effectiveness of each of these three modes. These variables are (1) temperature, (2) condition of surfaces and (3) gas velocity. Temperature is the predominant variable; it affects all three modes of transfer, in each case a temperature gradient being necessary. The condition of surfaces affects principally two modes of transmission, convection and conduction; while gas velocity affects simply convection.

BOILER-OPERATION CHART

Relations derived between the heat absorbed by the boiler, and the two variables, *flue temperature* and *gas velocity*, are combined into a single chart, Fig. 5, which is the boiler-operation chart, and corresponds to the furnace-operation chart previously shown. It expresses the relation of efficiency and capacity to the fundamental factors—temperature and velocity of the gases.

COMBINED BOILER-UNIT OPERATION CHART

Following this separate treatment of the two elements of the boiler unit—the furnace as a heat liberator and the boiler as a heat absorber—the paper here combines the results of the two analyses. As an example of such procedure there is presented in Fig. 6 the combined boiler-unit-operation chart.

It is evident that the factors governing furnace operation also determine the variables of boiler operation. The gas passing through the boiler is simply the air of combustion plus the weight of gasified coal (corrected, if necessary, for infiltration). The temperatures in the boiler are governed by the combustion conditions in the furnace. Hence, overall boiler efficiency and capacity are to be expressed simply in terms of the furnace variables—*thickness of fuel bed* and *pressure drop through fuel bed*. In the case presented here fuel bed thickness is indicated by weight of air and pressure drop, and these values therefore become the criteria of combined performance. The function of flue temperature is simply a check upon the condition of the heating surfaces. The combustion rate curves shown on the chart are of value only in assisting in the proper maintenance of fuel bed. However, this information is not necessary, since an insufficient fuel supply shortly disturbs the prescribed relation between air and pressure drop. Reference to the data shows very little variation in the character of the coal used in the tests, the results of which have been here presented.

The combined boiler-unit-operation chart brings out the essential importance of the variable factors which have been selected as determining performance. It supplies the information whereby the firemen may operate with maximum efficiency for each different load. It establishes the relation between efficiency and economy wherewith the economic policy of the boiler room may rationally be planned. Lastly, a study of the chart and of the reasons for its characteristics becomes a sound basis for improvement in design.

In conclusion the writer states clearly his position, which is not an unqualified acceptance of any single system of analysis, but rather the acceptance of the *principle* of systematic analysis. He believes there is no engineering problem which is immune to this principle.

An appendix describes the procedure for convection tests and for the determination of radiation heat, and discusses the furnace and stoker characteristics.

RADIATION ERROR IN MEASURING TEMPERATURE OF GASES

By HENRY KREISINGER, PITTSBURGH, PA.
Member of the Society

AND

J. F. BARKLEY,[1] PITTSBURGH, PA.

Of the errors entering into the determination of the average temperature of a stream of hot gases surrounded by colder or hotter surfaces, the radiation error is the most serious one and the most difficult to correct. Ordinary temperature measurements made with commercial devices under such conditions are from 5 to 25 per cent in error. If the surrounding surfaces are cooler than the gases, the temperatures indicated by the measuring instrument will be too low; or if the surrounding surfaces are hotter, as is the case in regenerating furnaces, they will be too high.

The object of this paper is to show primarily how large the radiation error may become under certain conditions of temperature measurements, and that judgment must be used in interpreting the accuracy and the value of temperature readings.

The radiation error is due to the fact that, to a large extent, gases are permeable to radiation. When a temperature-measuring instrument is immersed in a stream of hot gases surrounded by cooler surfaces, it absorbs heat from the gases by convection and its temperature rises. As soon as its temperature exceeds that of the surrounding surfaces, heat passes by radiation from the instrument to these surfaces through the intervening gases. Thus the instrument receives heat from the hot gases by convection, and gives off heat by radiation to the surrounding colder surfaces. The temperature of the instrument continues to rise with a decreasing rate, until the quantity of heat it gives off is equal to the quantity of heat it receives; the temperature then remains constant. Under these equilibrium conditions the temperature of the instrument is between that of the stream of gases and that of the surrounding surfaces; in other words, it is lower than the temperature of the gases which it is intended to measure.

In a similar way, when the instrument is inserted in a stream of gases surrounded by surfaces hotter than the gases, and when equilibrium conditions obtain, the temperature of the instrument is somewhere between that of the surrounding surfaces and that of the stream of gases; in other words, it is higher than the temperature of the gases which the instrument is supposed to measure. The difference between the temperature of the gases and that indicated by the instrument is the radiation error.

The magnitude of the radiation error depends on: (1) the size of the part of the instrument exposed to the gases and the radiation, and (2) the difference between the temperature of the gases and the temperature of the surrounding surfaces. The smaller the exposed part of the measuring instrument, the smaller the radiation error; also, the smaller the difference between the temperature of gases and the temperature of the surrounding surfaces the smaller the radiation error. In the measurement of the temperature of gases only the first-named factor can be controlled. The second factor is fixed by the kind of apparatus and its operation.

[1] Junior Electrical Engineer, U. S. Bureau of Mines.

For presentation at the Spring Meeting, Cincinnati, Ohio, May 1917, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. The paper is here printed in abstract form and advance copies of the complete paper may be obtained by members gratis upon application. All papers are subject to revision.

Of the instruments used in the measurement of temperature of gases, the thermocouple lends itself the best to the reduction of its size. It can be made so small that the radiation error is negligible for practical purposes. The correct temperature would be indicated only by a thermocouple having an exposed hot junction made of wires of zero diameter, which, of course, is a physical impossibility.

The effect of the size of thermocouples is shown in Fig. 1, which gives two sets of temperature measurements of the gases passing through a Babcock and Wilcox boiler fired with natural gas. One of these sets of measurements was taken with thermocouples having the hot junction made of wires 0.008 in. in diameter and the other made of tubes about 0.500 in. in diameter. This large couple is about the size of commercial instruments used for such purposes. Several thermocouples of each size were made and clamped together in pairs, each pair containing a large couple and a small couple, with their hot junctions about $1\frac{1}{2}$ in. apart. These pairs were placed at different points along the path of gases, indicated by the small circles and designated by the letters *A, B, C, D, E, F* and *G* in Fig. 2. All the couples were connected to a central switch and read in rapid succession with a portable potentiometer. While the readings were taken the furnace conditions were kept uniform, which was a comparatively easy task with the gas firing.

In Fig. 1 the abscissae are the approximate lengths of the paths of gases, measured from the position of the first pair of couples *A*. The full heavy curve connects the readings obtained with the large couples, and the full light curve the readings obtained with the small couple. The dotted curve above the full curves gives the probable true temperature of the gases, obtained by extrapolation from later curves. The curve near the bottom of the figure (drawn with dashes) gives the approximate velocity of the gases computed from the volume of gas burned, the chemical analysis of the products of combustion and the true temperature of the gases. The small black circle at the upper left hand corner gives the furnace temperature as measured with the Wanner optical pyrometer sighted through one of the gas burners, as shown in Fig. 2.

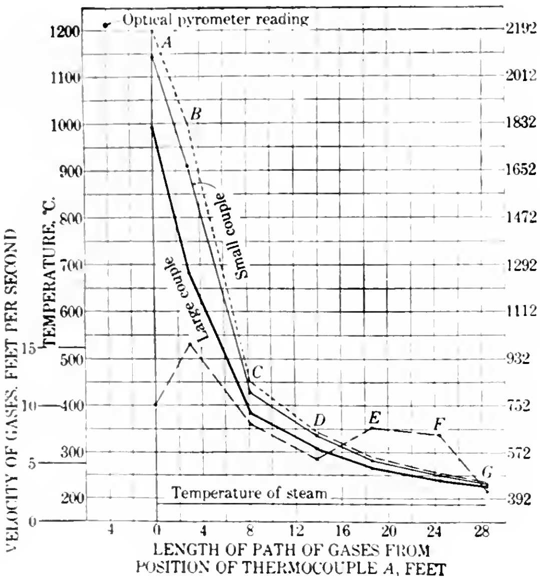

Fig. 1

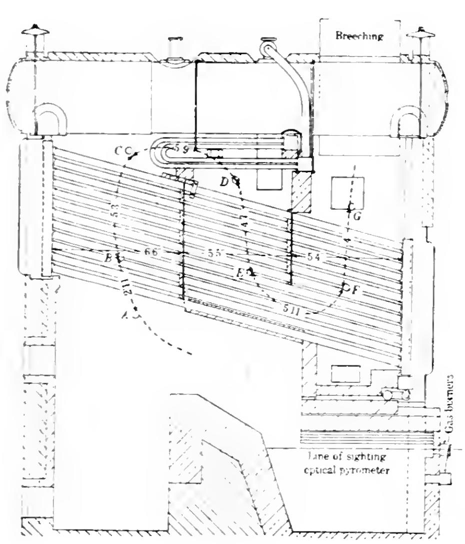

Fig. 2

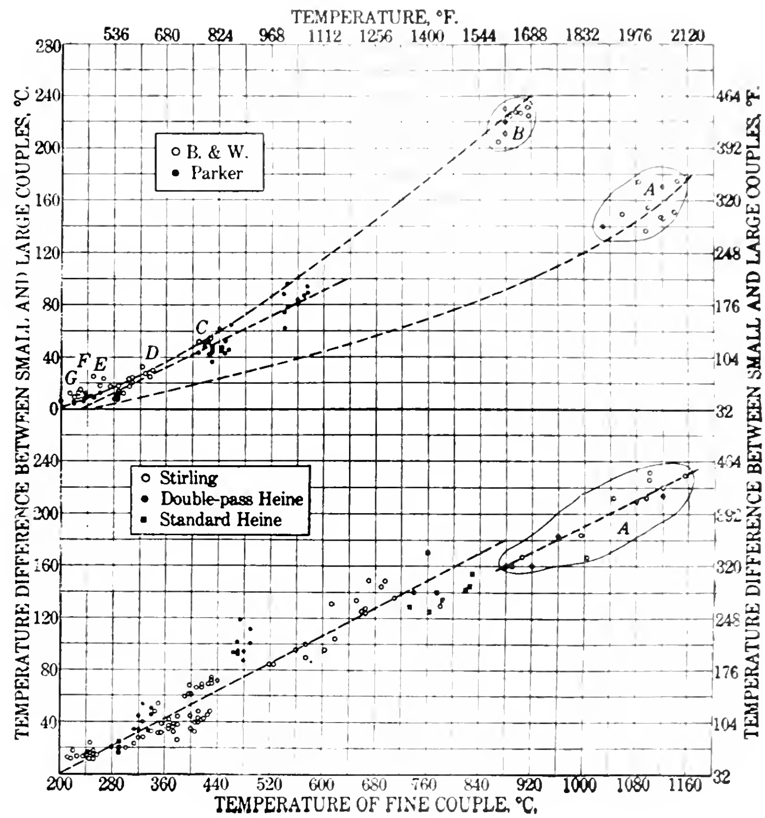

Fig. 3

Fig. 1 Temperature of Gases as They Pass Through Babcock and Wilcox Boiler

Fig. 2 Setting of Gas-Fired Babcock and Wilcox Boiler in Which the Measurements Were Made. Total Heating Surface, 3400 Sq. Ft.; Steam Pressure, 165 Lb. by Gage.

Fig. 3 Effect of Temperature of Gases on Radiation Error in Various Types of Boilers

The two full curves of Fig. 1 indicate that the small couples consistently showed temperatures considerably higher than the large couples, although the small couples themselves read somewhat too low. The difference between the readings of the two couples is nearly proportional to the difference between

[illegible] temperature of the gases and the temperature of the surrounding boiler surfaces, which was about 50 deg. higher than the temperature of steam in the boiler. The large couple at B shows a radiation error of about [illegible] deg. Fahr., whereas the small couple at the same place indicates an error of only 150 deg. Fahr.

Fig. 3 shows how much lower the large couples read than the small ones when the couples were placed in the boiler settings of five of the common types of water tube boilers. The readings were plotted on two charts to avoid crowding the points. With the exception of the groups marked A, all the readings were obtained with the thermocouples placed among the tubes, or in other places where they were almost totally exposed to the heating surfaces of the boilers.

The group A of the Babcock and Wilcox boiler was obtained with the thermocouple placed in position A, Fig. 2. In this position the thermocouples were exposed partly to the boiler tubes and partly to the brick walls and the clay-tile furnace roof, which latter surfaces were much hotter than the boiler tubes. Therefore the thermocouples did not lose as much heat by radiation as those couples which were completely surrounded by the boiler tubes, and their radiation error was smaller.

Group A of the lower half of Fig. 3 was obtained with the couples placed about 1 ft. above the arch and 1 ft. from the front nest of tubes in a setting of a standard Stirling boiler. They were therefore exposed partly to the boiler tubes and to some extent also to the hot brickwork of the furnace. Therefore the radiation error of these couples was somewhat smaller than the radiation error of the other couples completely surrounded by the boiler tubes.

Dotted curves were drawn through the groups of points representing readings of couples having nearly the same exposure to indicate that the radiation error is roughly proportional to the temperature of the gases.

The paper concludes with a determination of the nature of the relation between the radiation error and the size of the hot junction of a thermocouple.

DEVELOPMENT OF SCIENTIFIC METHODS OF MANAGEMENT IN A MANUFACTURING PLANT

By SANFORD E. THOMPSON, WILLIAM O. LICHTNER, KEPPELE HALL, AND HENRY J. GUILD [1]

THE development of scientific methods in manufacturing is being recognized almost universally as an essential to economical management. We say *recognized,* but this must be qualified by the acknowledgment that in the majority of concerns who accept this as a theory the treatment has been superficial instead of covering the development of plans which are accurate, exact, based on facts, and which account for all variable conditions. An encouraging feature of the situation lies in the fact that the most scientifically managed shops realize that they have by no means reached the ideal. In fact, a truly scientific development necessarily shows up the deficiencies as it proceeds. On the other hand, too many plants are settling back into self-sufficiency after establishing a so-called *efficiency department*—a most worthless piece of mechanism as ordinarily conducted—and a *cost system* which at best indicates how money is lost, and not how conditions can be improved.

SCOPE OF PAPER

A large proportion of the published matter relating to the application of scientific methods of management has pertained to the machine shop. In this paper it is the aim of the authors to present in considerable detail an outline of the development of scientific methods as applied to the ordinary manufacturing plant. At the same time, to make this more of a concrete illustration, the discussion will be centered in the plants known as the Eastern Manufacturing Company at Bangor and Lincoln, Maine, one of the largest concerns in the country manufacturing writing paper as its final product.

The development of scientific methods at these mills, however, is not, as one might assume, descriptive of simply a single and comparatively localized industry. As a matter of fact, the processes involved in pulp and paper making are similar in type, so far as management methods—not in specific technique—are concerned, to a vast number of industries. The treatment, for example, involves the scientific development and standardization of processes; the job analysis of hand and machine operations; the systematizing of stores, including supplies, raw materials and material in process; the introduction of planning methods to control very diverse conditions; the training of the worker; and the coöperation of the workers with the management through the Service Department, and personal relations.

In treating the subject, it is proposed after a brief summary and a statement of general principles to take up the plan of control of manufacturing and the methods adopted in the different processes to standardize practice.

INITIAL CONDITIONS IN THE PLANT

The plant at Bangor manufactures writing paper of high grade and also operates its own pulp mill, part of the product of which is for use in the paper and a part for sale. The Bangor mills employ some 800 people.

The individual processes group themselves into

1 manufacture of sulphite pulp from spruce wood
2 manufacture or making of paper from rags and sulphite pulp
3 finishing of the paper to produce the various finishes required for writing paper.

With the last is included the manufacture of the wooden boxes or cases for shipping the paper.

Before beginning the introduction of the more intimate analysis of the methods and processes, the plant had been brought during the previous two years to a stage much above the average plant of the old type of management in efficient operation. In 1914 it was decided by the directors to introduce scientific methods so as to go down to the bottom of things and develop standard methods of handling materials and labor.

RESULTS

The results secured by the scientific standardization of the various operations in combination with the routing system and bonus plan are briefly as follows

[1] Superintendent of Paper Mill, Eastern Manufacturing Co., Bangor, Maine. Other authors are members of the Society.

For presentation at the Spring Meeting, Cincinnati, Ohio, May 21 to 24, 1917, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. The paper is here printed in abstract form and advance copies of the paper may be obtained by members gratis upon application. All papers are subject to revision.

a increase in production in the paper mill of 35 per cent
b increase in the pulp mill from 35 tons to 50 tons, or 42 per cent
c average increase in wages of 40 per cent
d reduction in cost per ton of paper production, notwithstanding increased wages, of about 25 per cent[1]
e saving amounting to several thousand dollars per month in materials
f control of production throughout the plant
g development of the spirit of coöperation between management and employees.

The reduction in cost in spite of the increase in wages is due to three things

1 fewer employees per unit of work
2 reduction of overhead costs through the increase in production with the same plant and non-productive help
3 savings in materials.

THE PROCESS OF PAPER MAKING

Paper making, today, both in method and machinery, is substantially the same as it was one hundred years ago. It has been carried on during all this time by using traditional methods transmitted from one generation to another.

The process consists in brief of beating the "furnish," that is, the raw materials, in a large tub or beating engine, passing this through jordan machines, and then on to the paper machine, after which it is cut and finished in a multitude of ways.

SCOPE OF DEVELOPMENT

Scientific management consists fundamentally in finding the best way of doing a thing and putting the plan into execution.

The logical process in the development of scientific methods is to begin with the handling, classification, and storage of the raw materials; next establish control of the manufacturing processes, and finally establish by scientific investigation standards of material and standard practice for operating the plant.

It is evident that there are two distinct features involved in this: *first,* the introduction of a system in management, and *second,* the establishment of standards. It must be recognized very clearly—and it is because of lack of appreciation of this point that scientific management is confounded with mere mechanism—that system alone is never in itself the goal. System is merely the tool and a necessary tool for control. It is the classification of facts, the job analysis, the intimate study of conditions, that produce the real results in output, in quality, in elimination of fatigue, in basic coöperation and pulling together between the men and the management.

These are principles of general application. The actual work to be accomplished presents in different manufacturing establishments problems singularly alike. The methods of procedure, for example, at the Eastern Manufacturing Company, were similar to those required in almost any plant operating under the ordinary type of management.

PLAN OF ORGANIZATION

The work was undertaken in accordance with the following plan

1 classify the product so as to eliminate the confusion caused by a multiplicity of trade names and designations for the same article, and permit of keeping a proper balance of stock of the various grades, weight, ream, size, and finishes for promptly filling orders.
2 develop a system of routing controlled by a central planning department that will
   - insure orders being filled in the proper sequence
   - designate the required material for every order
   - eliminate wasted time of men and machines by always having a definite job ahead of each operator and each machine
   - move materials promptly from one operation to another with a minimum amount of confusion and delay.
3 make scientific job analysis of every operation to establish standards of materials and practice with an increased output, and yet no undue exertion; and fix rates and bonuses based on these scientific studies that will permit of a largely increased wage to the worker and decreased cost of production.
4 develop the personnel of the whole organization—management and employees—to a point that will insure a large measure of coöperation by functionalizing duties, by training, by assuming responsibilities, by recognizing merit, and by encouraging any expression of thought which will facilitate the work in any way whatever.

CONTROL THROUGH THE PLANNING DEPARTMENT

The Planning Department, centrally located in the Finishing Department Building, now controls in complete detail the progress of each order through the mill. The advantages gained over the old method are manifold and obvious

a It has placed in the hands of the two men who are responsible for the filling of all orders—the Production Man of the Making Department (formerly Assistant Superintendent) and the Production Man of the Finishing Department (formerly Boss Finisher)—absolute control of the sequence in which they shall be run. They decide *when* the work is to be done, the one, when the paper is to be made, and the other, when it is to go through the finishing department.
b It affords these production men precise information as to the exact status of any order in the mill at any time without leaving the room.
c Each clerk in the planning department has some definitely specified duty to perform and detailed instructions as to just how to do it. There is thus a trained corps of men and women, each an expert on his own job, who are employed in planning in advance the details of each step of the foreman or of the workman himself after the job has been started.
d The condition of each department and of every machine or worker in that department as regards supply of work is shown by the planning department control board, and permits the shifting of employees from one department to another, in order to prevent congestion of work or lost time on machines.
e It is impossible for anyone to be out of work without the fact being known. In fact, conditions can be foreseen and provisions made to meet them.

FUNCTIONS OF PLANNING DEPARTMENT

The Planning Department performs the following functions

a receives all orders from the Sales Department and acknowledges them the day they are received with a promised date of shipment

[1] This applies to conditions before the recent increase in cost of raw materials.

[illegible] the sequence in which jobs are to be run

routes each individual order to the machines and work places at which the different operations are to be done, sometimes weeks ahead of the starting of the order

c makes out in advance the time tickets which will be given to the operators when they are assigned a job

keeps each machine and work place supplied with work

e directs and controls the moving of materials and orders from operation to operation

f transfers operators from one job to another so that every worker in the mill always has some defined task to work on.

PLANNING THE MAKING OF PAPER

The chief aims in routing the materials and planning the running of the different kinds of paper is to (1) produce uniformity of product, (2) reduce number of furnishes, (3) get the paper out on time, and (4) avoid changes on the machines by grouping orders. Careful planning of the runs avoids loss of time in shut downs, and also permits the arrangement of colors to avoid extensive washing up, so that whites can be runs consecutively, and when colors are run that the changes be made from dark to light instead of from light to dark; also changes in deckle width can be laid out to best advantage.

To accomplish these aims the production man of the making department accumulates the different orders, determines from his records, not merely by memory, the time required for each kind of paper, and plans out the dates when the various lots can be run to the best advantage, and from this order of work the production man prepares a schedule or running list for each of the three paper machines. The route sheets and "stores issues" are made, indicating the way each order is to be handled, and the material is to be used, and the individual time tickets are made out and posted.

ECONOMY AND QUALITY DUE TO UNIFORMITY IN BEATING

One of the fundamental processes of paper making is the treatment in the beating engines. The importance of uniformity in a process like this is little appreciated. The product must come up to a certain standard, and it is very necessary from the standpoint of cost, not merely that this standard be maintained, but also that material be not wasted by improper mixtures, and to provide for unnecessary variations.

STANDARDIZATION OF BEATING

The strength of the product resulting from the beating is dependent upon the length of time and manner of beating the fibers, which is controlled by the set of the beater roll. The variables which had to be considered and studied in the making of paper are

1 control of amount of bone dry stock put into beaters
2 control of density of stock, that is, percentage of water
3 development of proper method of beating for maximum strength, this being dependent upon set of beater roll at start and the varying of beater roll during the process of beating
4 development of proper methods of testing for
   a density
   b fiber length
   c fiber strength
   d slowness
   e set of beater roll
   f hand sheets
   g velocity of stock in beater
   h strength of each of the raw materials
5 determination of relation between proper method of beating and proper method of jordaning and of running on paper machine.

The investigations of these various conditions have been carried on so that at the present time it is possible to know what is going into each furnish, both as to percentages of raw materials and density, and to fix definite times of beating with certainty of uniform results in product. With the information already obtained it is now possible to continue the more intimate investigation with a view to even more definite control.

Through the investigations already made and the routing of the materials and labor, the saving in materials has reached a sum of several thousand dollars per month.

INCREASE IN OUTPUT OF PAPER MACHINES

During the period while the investigation was being made on the beaters it was found advisable to increase the output of the paper machines. This could be accomplished in three ways (1) by increasing the speed of the machines; (2) widening the sheet on the paper machine, or, as it is technically known, increasing the deckle width, and (3) reducing the number and length of shutdowns through better planning of the orders.

Investigation showed that the speeds of the machines for the same furnish at different times would vary as much as 50 per cent through variation in the condition of the stock and lack of uniformity. As a result of the studies definite speeds were established for each furnish and specified to the man on the machine with each order. It was found possible to increase the speeds materially over the average of the old speeds.

The output was further increased by increasing the deckle width of the paper from time to time. The number and length of the shutdowns were reduced through careful planning of the runs.

REDUCTION OF HOURS

The hours were reduced in the Finishing Department in January, 1916, from $55\frac{1}{2}$ to 50 per week. The bonus times were left the same and no piece rates were increased, so that the actual labor cost to the company was increased. However, a comparison of outputs in a single department indicated that the parties on piece work maintained the same production in the shorter day that they had been turning out in the longer day.

STANDARDIZATION IN THE SULPHITE PULP MILL

During the progress of the development in the paper mill, steps leading toward the standardization of methods in the sulphite pulp mill were in progress, and soon, as a result of the satisfaction with the bonus system in the paper mill, there was a demand on the part of the men for the introduction of bonuses in the pulp making.

The problem was of particular interest because, on account of the continuous process, the wood, after the preliminary treatment in the wood room, passed through to the finished pulp without handling. The output is chiefly controlled by the men handling the digesters which cook the chips. The results were accomplished by scientific studies of the different processes, which determined the standard methods to follow to produce the greatest uniformity. The cooks, for example, were given definite curves of temperature and pressure to follow, and

were given bonuses for keeping within the limits set. This resulted in a reduction in the time of cooking, a greater uniformity in product, and the development of initiative on the part of the workmen. A curve has been plotted giving a comparison of the cooking time before and after the establishment of standards, and shows how greater uniformity was obtained. As a result of this uniformity the time of cooking was reduced materially and the output largely increased.

CLASSIFICATION OF PAPER

In analyzing the affairs of any manufacturing establishment producing a great number and variety of articles, the lack of systematic classification of the product is evident. It frequently occurs that no list of the various items can be found, and that there are very imperfect records of the sales of each. This company makes a great variety of grades of paper in many different colors, sizes and weights, and it is necessary to standardize the names of the product before the product itself can be standardized. A mnemonic symbol system was devised and is now in general use. By means of the symbol which is composed of letters and figures, the grade, base weight, color, size and finish of any paper is clearly indicated.

As a result of the classification, it was found possible to reduce the number of grades and to clearly define the amount of stock to carry. With the aid, also, of the running inventory or balance sheets it is possible not merely to keep track of stock on hand but to know just when new stock in any grade should be made up.

PERSONNEL

Scientific management is essentially a system of development—development of methods, and a development of the individual. A man or woman must be trained in order to become an efficient and skilful worker and to demand and receive high wages. Furthermore, a personal development must be attained to give a broadening point of view, so that he may see and appreciate the values of sincerity and truth, health and right living, self respect and self expression.

To further these aims a Service Department was organized under the direction of a trained social worker. The functions of this department are to

a employ all help and to keep a set of employee's record cards

b maintain a library for free circulation of books

c maintain a dispensary for treatment and care of sick or injured

d operate a cafeteria at which wholesome food may be served to employees at cost

e inspect the factory and see that it is maintained at high standards as regards cleanliness, ventilation, sanitation, and safety

f hear all complaints of employees regarding wages, treatment or conditions: investigate every complaint and when necessary see that matters are adjusted so that justice is always done.

g hear all complaints of foremen and department heads regarding employees; investigate these thoroughly and concur in any discipline or discharge that may be administered

h coöperate with employees in furthering any suggestions offered in regard to activities of a recreative or social nature

i coöperate with all outside interests, municipal or private, that may have for their object the betterment of conditions in the community.

DISK-WHEEL STRESS DETERMINATION

By S. H. WEAVER,[1] SCHENECTADY, N. Y.

THIS paper describes and applies a simplified method for determining the centrifugal stresses in a disk wheel of given irregular shape of section. Stodola's disk theory is assumed, together with his formula for disks of hyperbolic-section profile. The formulæ are then transformed so as to give the tangential stresses at the inner and outer radii in terms of the radial stresses, ratio of radii and shape constant of disk section.

For a given disk with a single hyperbolic outline, the tangential stresses are expressed in terms of the radial stresses or loads; and if the latter are known, the stresses are determinate. In case the disk-section outline would require to be fitted by two hyperbolas meeting at the same thickness of disk, the wheel section can be divided at the meeting point of the curves into two imaginary rings. The rings at the meeting point, by the continuity of material and same thickness, are held together by a radial stress common to both and have the same elongation and tangential stress. One can then write the tangential stress of the other at their common radii, giving one equation with one unknown quantity, the radial stress common to both, and all stresses are determinate. Thus any irregular shaped disk can be fitted with n hyperbolas, divided into n imaginary rings, and $(n-1)$ equations written for the common meeting points of the curves with $(n-1)$ unknown radial stresses, and the stress problem is solvable.

The solution of the stresses is given by formulæ containing six coefficients whose values are given as functions of the ratio of radii and hyperbolic outline of disk section. These coefficients are laborious to calculate, but should be used for accurate results. For commercial work, approximate equations are given which cover the practical disk proportions, and within the limits shown have a range of error of less than one per cent.

As a further labor-saving device when a number of disks are to be estimated, the approximate equations can be placed in an alignment-chart form. An appendix gives the range and proportion of the five charts required, which experience has shown to be the most useful. The number and size of these charts for accurate reading do not permit of reproduction.

A practical example is given showing the actual application to the usual disk wheel.

Clinkers in Boiler Furnaces. During many years' experience in designing, testing, improving, and operating furnaces, used for many purposes, no branch of this subject has been found that requires more consideration than the troublesome formation of clinkers in the furnace and the formation and growth of clinkers on furnace linings. In a great majority of cases this trouble can be either greatly reduced or avoided, for clinkers are formed by the fusion of the ash and refuse from the combustion of the coal in the furnace.—*Elec. Wld.*, Feb. 10.

[1] General Electric Company.

For presentation at the Spring Meeting, Cincinnati, Ohio, May 21 to 24, 1917, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS. On account of the mathematical nature of the paper its scope only is indicated here. Advance copies of the paper may be obtained by members gratis upon application.

AT the forthcoming Safety Session of the Spring Meeting, to be held under the auspices of the Society's Sub-Committee on Protection of Industrial Workers, will be presented and discussed a proposed code of safety standards for industrial ladders. This is one of a series of similar codes which the sub-committee has in preparation or in contemplation.

PROPOSED CODE OF SAFETY STANDARDS FOR INDUSTRIAL LADDERS

COMPILED BY THE SUB-COMMITTEE ON PROTECTION OF INDUSTRIAL WORKERS OF THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS

The word "SHALL" where used is to be understood as mandatory and "SHOULD" as advisory.

DEFINITIONS

The term *Fixed Ladder* as used in these regulations means a ladder that is substantially fastened to a structure in a fixed position.

The term *Portable Ladder* as used in these regulations means a ladder with but one section, which is used transiently at various locations.

The term *Extension Ladder* as used in these regulations means a ladder consisting of two or more parallel sections traveling in guides or brackets so arranged that it may be adjusted to variable lengths.

The term *Portable Step Ladder* as used in these regulations means a ladder so constructed as to be self-supporting.

The term *Fire Ladder* as used in these regulations means a ladder used exclusively for fire purposes.

The term *Trolley Ladder* as used in these regulations means a ladder the movement of which is confined in permanent guides or ways at top or bottom, or both.

The term *Sectional Ladder* as used in these regulations means a ladder consisting of two or more sections so constructed that the sections will telescope into each other.

The term "*A*"-*Ladder* or *Scaffold Ladder* as used in these regulations means a ladder whose parts, each equivalent to a straight ladder, are hinged at the top to form equal angles with the base.

SECTION 1 GENERAL

a Where stairways are not provided, fixed ladders should be used for access to elevated positions; where fixed ladders are not suitable, portable ladders should be used.

b Ladders shall be numbered, or otherwise designated, and regular inspections shall be made of their condition.

c The use of broken or weak ladders, or ladders with missing rungs, is prohibited.

d When defects develop to such an extent that the ladder is to be permanently discarded, it shall be destroyed.

e Side rails, where wood is used, shall be straight-grained. Knots one-half (1/2) inch or less in diameter will be permitted when they are in the center of the rails. The following thoroughly seasoned woods should be used: Northern spruce, Oregon pine, Norway pine, yellow long-leaf pine, or Oregon fir.

f Rungs shall be inserted in holes in the side rails and kept from turning, and shall not exceed fourteen (14) inches in length at the top.

g Wooden rungs shall be straight-grained, free from splinters, and absolutely free from knots. The following woods should be used: White ash, white oak (3rd growth), or hickory.

h Steps, where wood is used, should be constructed of the following woods: Northern spruce, Oregon pine, Norway pine, or oak.

i Ladders shall have a uniform step or rung spacing of twelve (12) inches on centers. [Mason ladders having a uniform spacing on centers of ten (10) inches and fire ladders having a uniform spacing of fourteen (14) inches excepted.]

j Ladders shall be equipped with devices designed to prevent slipping. (Fixed ladders, portable step ladders, and "A"-ladders excepted.)

SECTION 2 FIXED LADDERS

Ladders designed to reach safety valves, cut-outs, etc., where speed of operation may mean a saving of life, should always be of a permanent type, securely fastened, and constructed of steel or iron.

a Ladders having side rails are preferred to the type made of U-shaped section embedded in wall or fastened to stack, etc.

b The pitch of ladders shall not be such that a man's position is necessarily below the ladder when climbing.

c Side rails, where metal is used, shall be not less than three-quarters (3/4) of a square inch in cross-section. A minimum size of two (2) inches by three-eighths (3/8) inch should be used. Where wood is used, they shall be not less than six (6) square inches in cross-section and shall be dressed on all sides. A section one and three-quarters (1 3/4) inches by three and three-quarters (3 3/4) inches (2 by 4 dressed) would be suitable for this purpose.

d Splice plates, where metal is used, shall be of the same size and material as side rails and shall be double-riveted or bolted. Bolts or rivets shall be countersunk on inside and shall be not less than one-half (1/2) inch nor more than five-eighths (5/8) inch in diameter, where cross-section does not exceed that of two (2) inches by three-eighths (3/8) inch. Where wood is used, there shall be splices on outside of side rails and joints shall be double-bolted. Carriage bolts shall be used. All splice pieces shall be chamfered at the ends.

e Rungs should be round. Where solid metal is used, they shall be not less than five-eighths (5/8) inch in diameter; where pipe is used, they shall be of equivalent strength; where wood is used, they shall not be less than one and one-half (1 1/2) inches in diameter and the tenon shall be at least one (1) inch in diameter or its equivalent in strength.

f Distances from front of rungs to nearest permanent object back of the ladder shall be not less than six and one-half (6 1/2) inches. There shall be a space clear of all obstructions in front of the ladder from bottom to top, of at least thirty (30) inches forward and of at least fifteen (15) inches either side of the center line of the ladder. [Ladders equipped with wells (cages) or their equivalent shall be excepted.]

g Ladders over thirty (30) feet in length should be pro-

For presentation at the Spring Meeting, Cincinnati, Ohio, May 21 to 24, 1917, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

vided with wells, unless the ladder is built in zig-zag sections and provided with platforms between sections.

h Fastenings shall be made of material equivalent in strength to the rails. Fastenings shall be made to wall by building in, by through bolts, or by expansion bolts grouted or leaded. The maximum vertical distance between fastenings or braces shall not be in excess of ten (10) feet.

i Ladders to landing shall extend a distance of at least forty-five (45) inches above the landing, preferably being goosenecked. The rungs may be omitted above the roof. Where a man must step a greater distance than eighteen (18) inches from ladder to roof, tank, etc., a platform shall be provided.

SECTION 3 PORTABLE STRAIGHT LADDERS

a Ladders over thirty (30) feet in length should not be used.

b Side rails shall have a minimum cross-section equivalent in strength to a northern spruce side rail of the following dimensions:

Up to and including 10 ft.	$2\frac{3}{8}$ x $1\frac{3}{8}$ in.
Over 10 ft. up to and including 18 ft.	$2\frac{3}{4}$ x $1\frac{3}{8}$ in.
Over 18 ft. up to and including 26 ft.	3 x $1\frac{5}{8}$ in.
Over 26 ft. up to and including 30 ft.	$3\frac{1}{2}$ x $1\frac{7}{8}$ in.

c Side rails should be spread so that the width of the ladder at the bottom will be greater than the width at the top, preferably by a taper of one-quarter ($\frac{1}{4}$) inch per foot of length.

d Rungs shall be equivalent in strength and wear to an ash rung of the following dimensions:

	Diameter	Tenon
Up to and including 24 in. in length. .	$1\frac{1}{4}$ in.	$\frac{7}{8}$ in.
Over 24 in. up to and including 30 in. in length	$1\frac{3}{8}$ in.	$\frac{7}{8}$ in.

e Portable ladders should be fully protected at their bases to prevent slipping. For use on wood or earth the bases should be provided with case-hardened steel spurs; or a disk similar to the one furnished by the National Affiliated Safety Organizations, consisting of a case-hardened disk, held in position on dowel pins by springs, cotters and nuts, is recommended. These spurs shall be kept sharp. On concrete floors, pivoted shoes with lead or carborundum faces may be used.

f When used on iron floors an attendant should be placed at the foot of each ladder.

g Whenever possible to use ladders with a gooseneck or hook at the top, these should be provided, as forming the best protection against accident.

SECTION 4 EXTENSION LADDERS

a Table 1 should be followed in the construction of extension ladders.

b Ladders should be equipped with safety locks.

SECTION 5 FIRE LADDERS

a The construction, use and maintenance of industrial fire ladders shall conform to the specifications herein set forth covering portable straight ladders (Section 3, Par. *a* excepted).

b A uniform step or rung spacing of fourteen (14) inches shall be used.

c Fire ladders should be painted red and shall be plainly marked "For Fire Purposes Only."

d Fire ladders shall not be used for any other purpose than that for which they are intended.

SECTION 6 PORTABLE STEP LADDERS

a Ladders over twenty (20) feet in length shall not be used.

b Side rails shall have a minimum cross-section equivalent in strength and wear to a northern spruce side rail of the following dimensions:

Up to and including 12 ft.	$\frac{7}{8}$ x 3 in.
Over 12 ft. up to and including 16 ft.	1 x $3\frac{1}{2}$ in.
Over 16 ft. up to and including 20 ft.	1 x 4 in.

c Front and back rails shall be so spread when the ladder is open that the spread at the bottom, inside to inside, shall be greater than the spread at the top, inside to inside, by an amount equal to or greater than one and one-half ($1\frac{1}{2}$) inches per foot of length of ladder. Minimum width between side rails at the top step, inside to inside, shall be not less than twelve (12) inches, with a taper of at least one (1) inch per foot of length of ladder.

d Steps shall be equivalent in strength and wear to a northern spruce step of the following dimensions:

Up to and including 12 ft.	$\frac{3}{4}$ x $4\frac{1}{2}$ in.
Over 12 ft. up to and including 16 ft.	$\frac{7}{8}$ x $4\frac{1}{4}$ in.
Over 16 ft. up to and including 20 ft.	1 x $4\frac{1}{2}$ in.

e Steps shall be trussed and screwed or bolted to the side rails. Nails shall not be used as sole fastenings.

f An automatic locking device to hold the front and back rails securely in position shall be an integral part of each ladder.

TABLE 1 CONSTRUCTION OF EXTENSION LADDERS

SIDE RAILS:
Up to and including 44 ft. long: Material, Norway pine, clear and straight-grained, free from knots.
48 ft. to 60 ft. long: Material, Oregon fir, clear and straight-grained, free from knots.

RUNGS:
Material: Oak, ash or hickory, straight-grained, free from knots, and [illegible] and tough.
Dimensions: $1\frac{1}{4}$ in. diameter at center; taper to $1\frac{1}{8}$ in. diameter, straight-turn to $\frac{7}{8}$ in. diameter for holes in side rail.

LADDER DIMENSIONS

Length, ft.	Dimensions of side rails (cross-section same at both ends), in.	Distance between side rails, top section, in.	Distance between side rails, bottom section, in.	Vertical distance between rungs, in.
20, 22, 24, 26	$2\frac{3}{4}$ x $1\frac{1}{8}$	$12\frac{1}{4}$	$14\frac{3}{4}$	12
28	$2\frac{3}{4}$ x $1\frac{1}{4}$	$14\frac{1}{4}$	17	12
32, 36	$2\frac{3}{4}$ x $1\frac{3}{8}$	14	17	12
40	$3\frac{1}{4}$ x $1\frac{3}{8}$	$15\frac{3}{4}$	$18\frac{3}{4}$	12
44	$3\frac{1}{4}$ x $1\frac{5}{8}$	$17\frac{3}{4}$	$20\frac{3}{4}$	12
48, 52	$3\frac{1}{2}$ x $1\frac{1}{2}$	$17\frac{1}{2}$	$20\frac{3}{4}$	12
60	$3\frac{3}{4}$ x $1\frac{3}{4}$	18	$21\frac{3}{4}$	12

SECTION 7 "A" LADDERS OR SCAFFOLD LADDERS

a Ladders over twenty (20) feet in length should not be used.

b Side rails shall have a minimum cross-section equivalent in strength and wear to a northern spruce rail of the following dimensions:

Up to and including 12 ft.	$1\frac{1}{4}$ x $2\frac{3}{4}$ in.
Over 12 ft. up to and including 16 ft.	$1\frac{1}{2}$ x 3 in.
Over 16 ft. up to and including 20 ft.	$1\frac{1}{2}$ x $3\frac{1}{2}$ in.

c Side rails shall be so spread that the width of the ladder at the bottom, inside to inside, shall be greater than the width at the top, inside to inside, by an amount equal to or greater than one and one-half ($1\frac{1}{2}$) inches per foot of length of ladder.

d Supports shall be equivalent in strength and wear to an ash bearing one (1) inch by two (2) inches. They shall be straight-grained and absolutely free from knots, shall have tenons not less than five-eighths ($\frac{5}{8}$) of an inch by two (2) inches, secured in place with wire nails. They shall be not less than three (3) inches from the top of the side rails. They shall be eighteen (18) inches on centers, and shall be staggered. The tops of side rails shall be cut on a bevel to prevent them from spreading. Hinges shall be wrought or malleable iron, bolted or riveted to side rails.

SECTION 8 TROLLEY LADDERS

a Ladders shall be suspended from tracks fastened securely to the ceiling or to the framework with which the ladders are connected. Tracks should be of wrought iron or wood, and should be tested to double the maximum of load for marginal safety. Tracks shall be constructed so that it is impossible for the wheels to jump the track, by having the wheels in pairs situated on opposite sides of a vertical flange or by having the track so shaped that it completely encloses the sides of the wheels. The extreme front and back wheels shall have a horizontal distance of at least eighteen (18) inches between their centers.

b The track wheels shall be rigidly fastened to the top of the ladder with suitable steel or wrought-iron brackets. These brackets may be fastened to a bolt connecting the two side rails of the ladder or to the top step. In the latter case the top step shall be provided with extra metal braces to the side rails.

c Side rails shall have a minimum spread, inside to inside, of ten (10) inches.

d Side rails shall have a minimum cross-section equivalent in strength and wear to a northern spruce side rail three and one-half ($3\frac{1}{2}$) inches by seven-eighths ($\frac{7}{8}$) inch.

e Steps shall be equivalent in strength and wear to a northern spruce step four and three-quarters ($4\frac{3}{4}$) inches by three-quarters ($\frac{3}{4}$) inch.

f Steps, where metal is used, shall be flanged downward not less than two (2) inches at both ends and secured by two bolts or rivets to each side rail. Where wood is used, they shall be inset in the side rails one-quarter ($\frac{1}{4}$) inch, glued and nailed; all, or at least alternate steps, shall be braced to the side rails with metal brackets placed under the steps.

g The base of the ladder shall rest on two wheels or castors.

SECTION 9 SECTIONAL LADDERS

a The bottom section shall be six (6) feet in length and shall have a minimum spread between rails at the base, inside to inside, of twenty-one (21) inches.

b Sections (intermediates) shall be six (6) feet in length and shall have a minimum spread between rails at the bottom, inside to inside, of thirteen (13) inches.

c The top section may converge with a minimum spread between rails at the bottom, inside to inside, of thirteen (13) inches.

d Side rails shall have a minimum cross-section equivalent in strength and wear to a northern spruce side rail of the following dimensions:

Up to and including 5 sections	$2\frac{3}{4}$ x $1\frac{1}{8}$ in.
Over 5 sections	$3\frac{1}{8}$ x $1\frac{1}{8}$ in.

e Rungs shall be equivalent in strength and wear to an ash rung one and three-sixteenths ($1\frac{3}{16}$) inches in diameter with seven-eighths ($\frac{7}{8}$) inch tenon.

SAFE PRACTICES

Use care in placing portable ladders before using them. If there is danger of ladder's slipping, have some one hold it. Do not place ladders too straight or at too great an angle, or they may fall, break or slip.

Never place ladders in front of doors opening toward the ladder.

Ladders should never be placed against window sashes. Screw a board across top of ladder to give bearing at each side of window.

Step ladders should be fully opened and locked in all cases before any one steps on them.

Always face ladder when ascending or descending.

Do not go up or down a ladder without free use of both hands. If material has to be handled, use a rope.

Never slide down a ladder.

Never use broken or weak ladders or ladders with missing rungs.

When defects of construction develop to such an extent that the ladder is discarded, it should be destroyed.

Ladders withdrawn from service for repairs should be sent to the repair shop or tagged as "Dangerous—DO NOT USE."

See that ladders you use have safety feet, and, where necessary, safety hooks at top.

Short ladders should not be spliced together, as they are not strong enough to be used as long ladders.

Safe practice demands that ladders be numbered, classified, and subjected to careful and periodic inspection. Ladders should be kept clean and free from dirt or splashings of paint or material. Imperfections or defects are not readily observed unless ladders are kept in good condition.

Iron and steel ladders should be coated with a preservative paint or composition. Wooden ladders, if used out of doors, should also be carefully treated with a suitable preservative.

A satisfactory practice is the storing of ladders upon brackets by arranging them against wall in such manner as to permit inspection without moving ladders.

Storage of ladders involves a separate problem. Shelter should be provided in all cases. If placed upright, 75 degrees will afford a safe angle; if racks are used, place the ladder on edge rather than flat; this will prevent trouble and danger of accident in withdrawing the ladder for use.

Safety bolts and hooks should be provided when the character of the work demands the attention of the workman or constitutes an element of danger.

CORRESPONDENCE

CONTRIBUTIONS to the Correspondence Departments of The Journal by members of The American Society of Mechanical Engineers are solicited by the Publication Committee. Contributions particularly welcomed are suggestions on Society Affairs, discussions of papers published in The Journal, or brief articles of current interest to mechanical engineers.

Reply to Comments on Welding Paper

To the Editor:

In reply to the several persons who entered into the discussion of my paper on welding by the metal-pencil electric-arc method, printed in the April issue of The Journal, I do not think that the term *autogenous* applies to this particular form of welding, because it so closely follows the cycle of conditions of ordinary forge welding, whereas in autogenous welding, fluidity is a necessary condition. The pencil form is the last form developed and ought to be differently named, since it actually is in the added metal the lowest-temperature weld of the newer forms.

In reply to Mr. McCabe, the temperatures in question are estimated from the color. In the metal-pencil electric-arc welding, watched through colored glasses, just the same putty-like condition occurs as in the ordinary forge welding. The estimate may be either above or below the actual temperature; it is used, more than for any other reason, to direct notice to the fact that fluidity is not a condition present in this last-developed form of spot welding, except that known as the Quasi Arc.

As to the elimination of the possible stresses set up in the weld, the figures as quoted by Mr. McCabe cannot apply to this form of welding. In this case the area is very much less, and being free from the highly expanded condition of fluidity (in many cases almost reaching vaporization), the differential for each degree of temperature is different and the internal stress less. However, no attempt is made to eliminate internal stresses, nor is this necessary, because these stresses are at a maximum only when new, and are constantly changing as time elapses. This is true of any of the later forms of welding wherein the bulk of the work is always cold and the part worked on made hot. The point to recognize here, and this is fairly well explained in my paper, is that in this form of welding these internal stresses are the least of any and consequently more readily and sooner neutralized. With this consideration, therefore, no differential per degree of temperature can be used.

The determining of the safety of a vessel by the electrostatic test is new to me. What I am familiar with is the hydrostatic test, and this is perfectly trustworthy when accompanied by hammering while the test is on, the test being applied to the customary amount, that is, one-half more than the running pressure under which the vessel is to work.

It is to be expected that the welding material would vary widely in any form of welding except the approved form of welding, which may vary some, but not widely, and except the form that my paper defends, and Mr. McCabe is justified in his conclusion regarding this, but I would suggest that the metal-pencil form of electric-arc welding should not be made to carry the burden of the failures of autogenous welding generally, since this form places the art on a newer and entirely different and safer basis.

In reply to Mr. Bierbaum, the disturbance of the adjacent metal is dwelt upon in my paper and was shown in the lantern slides used at its presentation, and these ought to be a conclusive answer. It is true that in all other forms of welding wherein fluidity is resorted to, the disturbance is considerable, and one slide used by Mr. Armstrong in further discussion of my paper shows the adjacent metal practically destroyed. I wish to dwell strongly on the fact that in this metal-pencil electric-arc method no such condition exists, and the adjacent metal is not disturbed to a fraction of the extent of that which takes place in gas and carbon-arc welding and in the approved form of welding embodied in the A.S.M.E. Boiler Code and entitled Forge Welding, and this is due to the extremely localized character of the process and also its great rapidity of action,—it does not have time enough to overheat so as to create the disturbance referred to.

In reply to Mr. Armstrong, his discussion practically embodies a paper in itself and describes a further improvement in this particular form of welding, viz: the metal-pencil electric arc, but wherein fluidity obtains as a condition; but this occurs to a degree beyond which it does not go and is controllable to a nicety, approaching as is described in my paper an automatic action, which can be depended upon to prevent vaporization or any carelessness regarding overheating exactly in the way I have described, and altogether analogous thereto. In analyzing this extended discussion, however, in his references to the chemistry of these welds Mr. Armstrong refers to the oxidizing which occurs around the crater when the metal pencil is fused. Now to obtain fusion a high voltage must be used with electrodes of this character, and the arc maintained abnormally long. In his slides this is shown, and he states "about 1/8 in." as the length of such arc, but it is safe to say that it must be more since the slides themselves show dimensions as practically full size, as in Fig. 3 and Fig. 4, page 315 of the April issue of The Journal.

While these metal arcs require more voltage than the arcs obtained otherwise, the voltages used with the pencil arcs are normally low, from 60 to 70, and with such voltages an arc cannot be held with a wire in size equal to 0.161 in. diameter or No. 8 B.W.G. more than about 1/16 in. Therefore, fusion under such conditions cannot take place, and the piece of plastic putty-like metal flies for the plate, being constantly pulled into it, and consequently does not have time to become fused and the oxide does not amount to enough to deserve any considerable attention. However, the little that is present in what Mr. Armstrong terms the *bare wire* is almost entirely absent in the slag-covered wire, and though a predetermined limited amount of fusion occurs, the deposited metal shown in the slides shows a remarkable similarity to the metal of the plate it joins. These slides also show the least disturbance of the adjacent metal and the added metal is as he says, "just the same as ingot steel." Taking his discussion in a general way, it is a strong vindication of the supremacy of the metal-pencil electric-arc method of welding, showing a remarkable and highly efficient improvement in the art.

Mr. Armstrong introduces for the first time the question of

[illegible] been corroded with [illegible] consider [illegible] upon it. In this regard I wish to say, however, [illegible] many pieces of torch welding wherein no corrosion has yet appeared. Iron and [illegible] are in evidence, such, [illegible] instances in plants, where there are innumerable things [illegible] occurrence, pieces wherein this claim is absolutely absent. Test pieces which I have furnished the Society and which have now been in their possession about a year, welded with the electric method, show absolutely no indication of corrosion. However, I claim that in the several other methods of welding referred to in this discussion, wherein fluidity takes place, disturbances are set up which produce conditions where the question of corrosion may be a consideration, but not under the form of welding in my paper, nor is it present in the perfected form of welding which Mr. Armstrong advocates, nor in the approved form of welding in the A.S.M.E. Boiler Code.

In reply to Mr. Mauck if he means that the metals "in all processes of welding" have to be raised to the point of fusion and no more, that is, just a plastic condition, then his discussion is not a criticism of the metal-pencil electric-arc welding, since that is just what takes place therein.

If there are no leaks when a moderate hydrostatic test to $1\frac{1}{2}$ times is applied, it shows that there are no porous or spongy places,—that the joint is solid. Then why a higher test? I do not think it necessary or advisable to carry the testing pressure to extremes and so unduly strain the vessel.

In conclusion, let me say that with the knowledge we have in our possession, derived from much investigation, many experiments and tests, all reduced to tables and curves, we now know just the right voltage to use, just how much current to have, just what are the right size pencils, together with proper direction of current, and the knowledge also which enables us to utilize other factors such as magnetism, slag protection and purifying agents. The process now contains nothing haphazard or problematical: it has been reduced to an exact science, and, therefore, belongs in the list of things that have become considered as settled.

E. A. WILDT.

Scranton, Pa.

WORK OF THE BOILER CODE COMMITTEE

THE Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York City.

Below are given the interpretations of the Committee as approved by the Council on April 20, 1917, in Cases No. 136 to 139, 141, 142, 144 and 145. In this report, as previously, the names of inquirers have been omitted.

CASE No. 136

Inquiry: Is it the intent that no pressure shall again be allowed on a boiler on which a crack has been discovered in a longitudinal seam, and that the boiler cannot be patched and again used, or may such a boiler be again put in commission after being patched and after passing a prescribed test?

Reply: It is the intent of Par. 384 to permanently discontinue the use of the shell or drum of a boiler, for steam boiler purposes, should a longitudinal joint crack be discovered in any plate or course of the shell or drum.

CASE No. 137

Inquiry: Is it permissible under Part 1, Section 2 of the Boiler Code, to use a smaller size of safety valve than is there specified, where a heating boiler is operated on the vapor system with open vents to the atmosphere?

Reply: It is not expedient to modify or amend the Code in the nature you request. Par. 348 and 358 cover your case, and refer to the boiler and not to the system.

CASE No. 138

Inquiry: Is it permissible in a superheater constructed with steel return bend headers to electrically weld the tubes into the headers?

Reply: Autogenous welding of superheater tubes to headers is not permissible under the Boiler Code if the strength of the weld be depended upon to resist the pressure tending to drive the tube out of the header. It is permitted for the sake of the tightness, but the strength of the weld at the joint must not be taken into account.

CASE No. 139

Inquiry: Is it possible to secure a smaller A.S.M.E. Boiler Stamp than the present $\frac{3}{4}$ in. stamp that is furnished to meet the requirements of Par. 332 of the Boiler Code? It is difficult to stamp thin plates with the present $\frac{3}{4}$ in. stamp on account of the rebound.

Reply: A new stamp will be provided, $\frac{1}{2}$ in. size, hammer type, and with the top end square, so that it can be either used as a hammer stamp or struck with a sledge.

CASE No. 141

Inquiry: Is there any objection to drilling and tapping holes in the shell of a boiler if they are properly reinforced?

Reply: It is the opinion of the Boiler Code Committee that there are no objections to drilling and tapping holes in the shell of a boiler if the same are properly reinforced according to the Code.

CASE No. 142

Inquiry: In a design of horizontal return tubular boiler, with a manhole located in the front head below the tubes, is it permissible under Par. 218 to insert tubes on either side of the manhole instead of through stays?

Reply: Tubes on each side of a manhole cannot be used in place of the through stays specified in the last sentence of Par. 218.

CASE No. 144

Inquiry: What are the requirements for the design of reinforcing liners for the inside of the cylindrical shell of a boiler?

Reply: Where reinforcement is necessary for openings which are not intended for pipe threads, the requirements of Par. 261 of the Boiler Code are to be followed.

CASE No. 145

Inquiry: Is it not better practice under Par. 316 of the Boiler Code to discharge feed water in the waterleg of a vertical firetube boiler about half way between the mud ring and the bottom head, than to discharge it against the tubes midway between the bottom head and the lowest water level?

Reply: It is the opinion of the Boiler Code Committee that Par. 316 does not permit of discharging the feed water in the waterleg of a vertical firetube boiler.

SOCIETY AFFAIRS

A Record of the Current Activities of the Society, Its Members, Council, Committees, Sections and Student Branches; and an Account of Professional Affairs of Interest to the Membership

THE officers of the Society are trying to make every member feel that this is a national society of the engineering profession. President Jacobus, last year, and President Hollis, this year, have made great sacrifices of their time and energy in order to visit the Sections, and I have supplemented their trips and have just returned from as far west as Oklahoma City.

The first place I visited was Cincinnati, where I met the Local Committee, who are arranging for the Spring Meeting. If they carry out the program they have planned, the Meeting will be the most complete I have known of, not only of this Society but of any other.

From Cincinnati, I went to Chicago to attend a conference on Engineering Coöperation, called by Dr. F. H. Newell, Mem.Am.Soc.M.E. An account of this conference appears elsewhere in this issue of The Journal. As I have lived a number of years in the West, I appreciate the point of view of a man who lives away from the headquarters of the national societies.

The theory on which these organizations, of which there is a large number, representative of the smaller societies as well as the larger societies, have gotten together, is that the engineering profession owes a duty to society and ought to take a part in public affairs, and the members of these organizations are correspondingly dissatisfied with the attitude of the National Engineering Societies in what they regard as an ultra-conservative policy.

Is it a proper ambition for an engineering society to aspire to such a position with relation to civic affairs that engineering matters coming up in the administration of communities be referred to the society? If so, how can it be fulfilled? This is a broad question which should be thought about carefully. Should engineering societies take a part in public affairs? What part should they have in public affairs?

Our Council is laboring with this problem sincerely, and is trying to strike the happy medium between avoiding taking sides on political and economic questions and giving engineering advice on matters which we do know about.

From Chicago, I went to Madison to the Student Branch there. We have forty-four Student Branches in the Universities and are getting the young men interested in engineering societies. They have their own societies and presiding officers. They have outside lecturers and papers presented by their own members. They learn how to speak in public before their mates. We are supplying, through the activities of the engineering societies, a feature which is not supplied by the majority of colleges in their regular curricula.

From Madison I went to Milwaukee, where we had a splendid meeting with members of the local committee of the Milwaukee Engineering Society, which is the nucleus about which the locals of the national engineering societies there gather. Then I returned to Chicago, where I met the Chicago local committee.

I then went to the Student Branch of the State College of Iowa and to the University of Kansas Student Branch, where they had an Annual Meeting which lasted all day, all arranged for by the students themselves and being addressed by outside lecturers. From there I went to the University of Oklahoma, just outside Oklahoma City, and in one of the coming states of the United States.

Just before I left New York on this journey, the Military Engineering Committee wrote to the presidents of each of the National Engineering Societies, suggesting that the ex

FELLOW MEMBERS

It is not necessary to call the attention of the Society to the unprecedented crisis before this country, because we all, as American citizens, know well that our country has embarked upon an undertaking fateful to the freedom of the individual.

The word "Democracy" does not express fully all that would be in store for us if we, as a nation, failed to do our duty by humanity, and by our country. Happily every member of our Society can assume that every other member is eager to make his contribution. I have been struck with that in the great amount of correspondence I have had during the past month, always asking the question, "How can I serve my country?"

The Society as a whole is doing all it can to coöperate effectively with the National Research Council, with the Council of National Defense, and with the War and Navy Departments, in the appointment of representatives to assist and coördinate the work of all engineering societies. Two of our members were selected for the National Research Council, two for the Council of National Defense, two for work with an Army Board on guns, and doubtless others will come forward, or be brought forward as the exigency arises.

As good citizens we should truly awake to the necessity of a well-trained army. We, as engineers, can help in this, not only by offering ourselves to the War Department and to the Navy Department, but also by assisting unselfishly in the industries, and in the promotion of increased farm production.

In our democracy we can best raise an army by sharing alike in its hardships, not trusting that the noblest and best of our young men will come forward to enlist for service, but putting the responsibility on all alike through some kind of universal service.

I have no permission to speak for the whole Society, but as its President, I urge every member to search his own conscience seriously for some method by which he can serve. The country depends upon us and we must respond.

IRA N. HOLLIS

[illegible] Committee be reconstructed and authorized to get out a complete set of instructions as to what a man should do who wished to serve his country. The Committee is now [illegible] the Joint Committee on National Defense and has, during the past month, prepared two circulars to send out to the membership with instructions as to how to join the Army and the Navy. We will send these out shortly.

A number of our members have responded to the call for national service, as the "Roll of Honor" published this month shows. This list will be supplemented from month to month by the names of members as they are enlisted. This first list [illegible] the particulars of commissions received by members in the Engineer Officers' Reserve Corps, the War Department having at this date issued a list of accepted commissions to March 15 only. Members who have accepted commissions in the Corps subsequently to this date, and any other members entitled to have their names inserted in the Roll of Honor, should notify me immediately.

The National Research Council has solicited the nomination of two of our members for their Engineering Committee and the Council of National Defense has advised us that they similarly will request us to nominate members for their Engineering Committee.

Calvin W. Rice,
Secretary.

Council Notes[1]

At the meeting of the Council on March 16 the following members were present: Ira N. Hollis, *President*, John H. Barr, C. H. Benjamin, R. H. Fernald, Arthur M. Greene, Jr., W. B. Gregory, F. R. Hutton, W. B. Jackson, D. S. Jacobus, C. T. Main, H. de B. Parsons, John A. Stevens, Wm. H. Wiley, *Treasurer*, and Calvin W. Rice, *Secretary*.

A.S.M.E. Boiler Code. The Chairman of the Committee proposed changes in the Code, together with interpretations in cases Nos. 140 and 143, which were approved and ordered published in The Journal. They appeared in the April issue.

Engineering Coöperation Conference. Paul P. Bird, H. C. Gardner, and Calvin W. Rice were appointed to represent the Society at a conference on Engineering Coöperation to be held in Chicago, March 28 and 29.

Military Engineering Committee. It was voted that the Committee on Engineer Officers' Reserve Corps of The American Society of Mechanical Engineers, which is part of a joint committee, coöperate with the other engineering societies and the United States Government, so that there will be one central committee of the engineering profession which shall assist the Government, and that the committee has power to select a suitable name, also to add to its membership, and that The American Society of Mechanical Engineers will be willing to assume its proportionate share of the expenses of a comprehensive work of advancing the preparedness for national defense.

Standardization Committee. C. F. Hirshfeld was appointed on this committee in place of H. G. Stott, deceased.

Student Branches. A student branch at the University of Oklahoma, Norma, Oklahoma, was approved.

Calvin W. Rice
Secretary.

On page 370 of the April issue of The Journal it was stated that the price of the book on The John Fritz Medal is $4.00. This is erroneous. The price is $2.50.

[1] The April Journal went to press before the March Meeting.

Past Presidents' Return from the Orient

Dr. Brashear, Mr. Swasey and Mr. Freeman have returned safely from their extended tour of the Orient, and were entertained at luncheon at the Engineers' Club of San Francisco on April 3. Vice-President Dickie has sent us a first-hand account of the reception, which is well worth reproduction in full:

It was no ordinary occurrence that brought out one hundred and seventeen of the best-known engineers of San Francisco on Tuesday April 3 to luncheon at the Engineers' Club. It is not often possible to have as guests at one time, three ex-presidents of one of the national societies, but fortune favored the engineers who practice their profession in the city of the Golden Gate. For in through that Western Gateway there floated three wise men from the Far East, such men as the engineer, be he civil, electrical, or mechanical, delights to honor—Dr. Brashear, Mr. Swasey, and Mr. Freeman.

Mr. C. T. Hutchinson, president of the club, and Mr. Shreve, chairman of the entertainment committee, secured the three noted engineers, who were seeking rest rather than excitement, and brought them to the club rooms, where they were received with manifest tokens of good will and respect and at 12.30 all proceeded to the dining room. Mr. Dickie acted as chairman, and after luncheon, with a few remarks appropriate to the occasion, introduced first Dr. Brashear who, in a beautiful address, carried these hard-working sober engineers up with him on angels' wings so that they might gaze for a while on the very heaven of heavens, and feel what engineers seldom feel—the bliss of wings and the glorious vision of distances that can only be measured in terms of light years. But after a hearty luncheon neither the doctor nor his audience could stay long up where he had drawn them, so gradually he let them down and talked awhile about the common things of the engineer's checkered career. This fifteen-minute address was a gem and will be long remembered by those who had the privilege to hear it.

The chairman then called upon Mr. Swasey for a few words, which resulted in a very helpful address on the growing importance of the engineer in the work of the world. Mr. Swasey said that while this old, selfish world was rather slow in acknowledging its great debt to the engineer, it has at last found out that it cannot even fight to any purpose without the engineer—and so he encouraged the young engineers before him, with the thought that their profession was a militant one, and that the future would become brighter for the engineer as the years rolled by.

Mr. Freeman spoke on the outlook of the Panama Canal, giving his experience as a member of the commission appointed by the President to investigate the effect of the landslides on the security of the canal as a reliable passage for shipping between the two oceans. Mr. Freeman, in a lucid address, cleared away any doubts that might be in the minds of his hearers, and what he said will always be referred to when the subject is under discussion.

The meeting with these three typical men in our profession will not soon be forgotten by those, especially the younger members, who had the rare opportunity to hear them; and it should also be noted that Dr. Brashear, Mr. Swasey and Mr. Freeman expressed their delight in having the opportunity to meet so many of the engineers of San Francisco.

If the student of engineering gets his training in the English classroom only, it is, at best, artificial: at worst, only speaking pieces. For training of this sort there is opportunity (and it is being taken advantage of) in engineering "topics" classes; but the best place is in the engineering society. If this is a student organization with faculty assistance and if students who really know something of some particular engineering problem and practising engineers make up the program, in the discussion of which all take part, such a society can accomplish more in training students to speak effectively than an unaided English teacher ever could.—*Engineering Education*, February 1917.

THE ENGINEERING SOCIETIES IN NATIONAL DEFENSE

THE JOURNAL takes great satisfaction in announcing the active participation in national affairs by members of the Society as fully set forth in the Society Affairs and Engineering Survey sections of this number.

The Society has been honored by the election of Prof. W. F. Durand, former president of the International Engineering Congress, to the National Academy of Sciences. This is in keeping with the announcement last year of the intention of the Academy to create a division of engineering coördinate with other divisions of the Academy, and from time to time to elect engineers to membership.

Mr. John R. Freeman has been elected a member-at-large of the National Research Council of the Academy of Sciences. Mr. Freeman, and Dr. W. F. M. Goss, already a member of the Research Council, have been designated as the Society's representatives on that body.

At the meeting of our Council on April 20, President Hollis reported that he and Dr. D. S. Jacobus had been selected by the Secretary of War as representatives of the Society on a special engineers' commission to serve with officers of the Army and Navy in determining gun mounts.

The following nominations were also made in response to invitations received from the National Research Council and the Advisory Committee of the Council of National Defense:

For membership on the Engineering Committee of the National Research Council, of which committee Mr. Gano Dunn, Mem.Am.Soc.M.E., is chairman, Prof. W. F. Durand and Charles D. Young.

For appointment on an Engineering Societies' Section of the commission of the Advisory Commission of which Dr. Hollis Godfrey, Mem.Am.Soc.M.E., is chairman, Dr. Ira N. Hollis and Calvin W. Rice.

In response to the request of the Director of the Bureau of Mines, the Council has nominated its Research Committee as a special advisory committee to the Bureau, and has also authorized the President to appoint two sub-committees, one on fuels and another on mine equipment. Prof. O. P. Hood, Mem.Am.Soc.M.E., and mechanical engineer at the laboratories in Pittsburgh, has been designated by Director Manning as secretary of the advisory committee of the engineering societies to the Bureau.

Mr. Frank A. Scott, vice-president and treasurer of The Warner and Swasey Company, has been appointed head of the General Munitions Board, as is noted in the Engineering Survey Section in this issue. Mr. Scott's appointment is one of the evidences of the helpfulness of the Society in the present crisis.

At the request of THE JOURNAL, the following letter has been prepared by Mr. Dunn, in which is clearly explained the relations of the engineering societies to the various agencies of national defense.

Letter from Mr. Gano Dunn, Chairman Engineering Committee, National Research Council

TO THE EDITOR:

The engineering profession, which has been so prompt to volunteer its professional and military services to the Government in support of national defense, is now in contact with the various government agencies, as follows:

First, through the Naval Consulting Board and its formerly existing Committee on Industrial Preparedness, with the origin and organization of which board the engineering profession is already familiar. Each of the national engineering societies, and certain other societies, by contributing two members to the Naval Consulting Board, has afforded the Navy and War Departments and the Council of National Defense a highly expert board for passing upon inventions and developing them in the new Government Laboratory that has been organized.

ENGINEERS' RESERVE CORPS

Second, in a more or less informal way, through the joint Committee on Engineers' Reserve Corps and the Military Engineering Committee of New York, the military services of engineers are being organized and offered to the Government, and an Engineers' Regiment is recruiting in New York.

The constitutions of the national engineering societies were found to contain such limitations that these societies could not take formal action in military matters. A little over a year ago the Military Engineering Committee organized itself through the spontaneous action of a group of leading engineers, including a number of presidents, past-presidents and other prominent officers of the national engineering societies, to an extent that gave the committee a character representative of those societies, although this character has only recently been confirmed by the action of the societies themselves.

NATIONAL RESEARCH COUNCIL

Third, through the National Research Council, created at the request of President Wilson by the National Academy of Sciences, "to bring into coöperation existing governmental, educational, industrial, and other scientific and research organizations, with the purpose of encouraging investigations of natural phenomena, the increased use of scientific research in the development of American industries, the employment of scientific methods in strengthening the national defense, and such other applications of science as will promote the national security and welfare."

The work of the National Research Council, the offices of which adjoin the offices of the Council of National Defense, is carried on through the agency of central committees covering each of the physical sciences and chemistry, mathematics, medicine, hygiene, agriculture and other subjects, including a Committee on Engineering. To this Committee on Engineering, each of the national engineering societies has contributed two representatives, and stands ready to contribute others as called for. With the engineers who are members of the National Research Council, these constitute the Engineering Committee.

The representatives so far named from the American Society of Civil Engineers are George F. Swain, Edgar C. Marburg and Clemens Herschel; from the American Institute of Mining Engineers, Pope Yeatman, Albert Sauveur, Charles F. Rand and George K. Burgess; from The American Society of Mechanical Engineers, W. F. M. Goss, John R. Freeman, C. D. Young, Wm. F. Durand, John A. Brashear, Hollis Godfrey, Howard E. Coffin and Ambrose Swasey; from the American Institute of Electrical Engineers, Frank B. Jewett, Clayton H. Sharp, Gano

[illegible] J. Skinner, Michael I. Pupin, [illegible] W. Stratton, Elihu [illegible] and John J. Carty from the American Institute of [illegible] Engineers, Lewis B. Stillwell.

The Engineering Committee, under formal request of the Council of National Defense, in a resolution dated February [illegible] 1917, addressed to the National Research Council, brings [illegible] the Council of National Defense, directly through [illegible] services of engineers in the realm [illegible] research, and it constitutes the connection between the Council of National Defense and the various national engineering societies, through which services offered by [illegible] to the President of the United States may be [illegible] of problems in scientific and engineering research.

In addition to supporting the Government in engineering research, the committee also brings to the aid of the Government, through the National Research Council, such general engineering services as are auxiliary to research where those services are needed by any of the other committees of the Council, as incidental to research problems on which they are at work.

The national engineering societies have a further relation to the National Research Council through the Engineering Foundation which those societies established to administer the munificent gift of Ambrose Swasey for the fostering of research in science and engineering. Through the action of the engineers, the whole available income from this gift is now devoted to the organization and operation expenses, but not the research expenses, of the Council.

As has been stated, the contact of the engineering profession with national defense, through the Engineering Committee of the National Research Council, covers only those services involved in science and engineering research, with the addition of such general engineering services as are auxiliary.

Other or general services in the engineering field are articulated with the national defense, as follows:

COUNCIL OF NATIONAL DEFENSE

Fourth, through an Engineering Section of that committee of the Advisory Commission of the Council of National Defense, which is under the direction of Dr. Hollis Godfrey, to whom the Defense Council has assigned supervision of general engineering matters, including education.

Dr. Godfrey is now in course of completing the formation of this committee by calling upon each national engineering society, and certain other engineering societies, to contribute two representatives whom he may appoint members of the Engineering Section of his committee, so that services needed by the Council of National Defense in the realm of general engineering may be placed at its disposal, either by the individual members of the committee or through them by other members of the engineering societies upon whom the Council of National Defense may call.

The above four channels indicate the broad extent to which the members of the engineering profession, in patriotic response to the country's need, have come forward to render services.

Yours truly,

[illegible], *Chairman, Engineering Committee, National Council.*

[illegible] is the text of letters received from the National Research Council and the Advisory Commission of the Council of National Defense inviting nominations from our Society on the Engineering Committee of the former and on the Engineering Societies' Section of the latter:

FROM ADVISORY COMMISSION OF COUNCIL OF NATIONAL DEFENSE

The American Society of Mechanical Engineers tendered its services to the President of the United States in support of the National Defense, and these services were accepted by the President who referred further relations with The American Society of Mechanical Engineers to the Council of National Defense.

As the member of the Advisory Commission of the Council of National Defense charged with matters pertaining to engineering, and authorized by virtue of my appointment by the President and by Act of Congress to appoint Committees for the purpose of assisting the Council of National Defense with advice on the carrying out of its plans, I desire to ask if you will designate two representatives from The American Society of Mechanical Engineers whom I may appoint members of an Engineering Section of my Committee, which representatives will be the means of putting The American Society of Mechanical Engineers into relations with the Council of National Defense so that the services offered by your Society may be available to the Council.

Upon the completion of the formation of the Engineering Section of my Committee, I desire to ask the representatives of the National Engineering Societies to meet me for a conference in Washington to make further plans by which the Government may derive the greatest benefit from the services those Societies have so patriotically tendered.—HOLLIS GODFREY, *Member Advisory Commission Council of National Defense.*

FROM THE NATIONAL RESEARCH COUNCIL

The National Research Council to increase its means of serving the Government in support of National Defense by enlisting through an Engineering Committee the services of a group of distinguished engineers drawn from the field of engineering research in each of the four main divisions of civil, mining, mechanical and electrical engineering.

In addition to services in the field of engineering research the Council has need of some general engineering services auxiliary to problems of research, and desires to be in a position to enlist such services in support of the general objects of the Council.

These objects are, to bring into coöperation existing governmental, educational, industrial and other research organizations with the purpose of encouraging the investigation of national phenomena, the increased use of scientific research in the development of American industries, the employment of scientific methods in strengthening the national defense, and such other applications of science as will promote the national security and welfare.

The relation of the National Research Council to the Council of National Defense is indicated by the following resolution, passed on the 21st of February, by the latter:

> RESOLVED, that the Council of National Defense, recognizing that the National Research Council, at the request of the President of the United States has organized the scientific forces of the country in the interest of national defense and for national defense, and to this end the Council of National coöperate with it in matters pertaining to scientific research for national defense and to this end the Council of National Defense suggests that the National Research Council appoint a Committee of not more than three, at least one of whom shall be located in Washington, for the purpose of maintaining active relations with the Director of the Council of National Defense.

The Executive Committee of the National Research Council would appreciate if on behalf of The American Society of Mechanical Engineers, you would designate two engineers skilled in engineering research, whom the Committee may appoint members of the Engineering Committee of the National Research Council, to render the services outlined in this communication and to serve as a means of calling upon other members of The American Society of Mechanical Engineers, for services that the National Research Council may need in support of the National objects herein referred to.—GEORGE E. HALE, *Chairman, National Research Council;* JOHN J. CARTY, *Chairman, Executive Committee;* GANO DUNN, *Chairman, Engineering Committee.*

ROLL OF HONOR

Members of The American Society of Mechanical Engineers Enlisted in the National Service

(First List)

ADAMS, CARROLL E., Private, Battery A, Rhode Island National Guard.

ADAMS, WALTER H., Captain, Engineer Officers' Reserve Corps*

ALLEN, WALTER C., Captain, Engineer Officers' Reserve Corps.

ALLISON, JOHN F., First Lieutenant, 3d Regiment, Penn Machine Gun Company, Fort Bliss, Texas.

ALLYN, ROBERT S., Major, 9th Coast Defense Command, C. A. C., National Guard, New York.

BEHR, F. J., Captain, Coast Artillery Corps, U. S. A., Hammond Radio Research Lab., Gloucester, Mass.

BELCHER, P. WILLIAM, First Lieutenant, Engineer Officers' Reserve Corps*

BENEDICT, B. W., Captain, 1st Illinois Field Artillery, commanding Battery F.

BERLINER, R. W., Captain, Engineer Officers' Reserve Corps.

BETTS, PHILANDER, Major, Engineer Officers' Reserve Corps.

BILGER, H. E., Captain, Engineer Officers' Reserve Corps*

BILLMYER, CARROLL D., Corporal, First Company, Coast Artillery Corps, National Guard of Virginia.

BIRNIE, ROGERS, Colonel, Sandy Hook Proving Ground, Fort Hancock, N. J., and Governor's Island, N. Y.

BOETTGER, ROBERT, First Lieutenant, Engineer Officers' Reserve Corps.

BRENNAN, JAMES, Captain and A.D.C., 7th Division, U. S. A.

BURROUGHS, JOS. H., JR., First Class Private, Company B, Engineer Battalion, National Guard, Pennsylvania.

BUSH, HAROLD M., Major, Ohio Battalion of Artillery, National Guard.

BUYERS, A. S., First Lieutenant, Coast Artillery Corps, U. S. A., care of Adjutant-Gen'l, U. S. A., Washington, D. C.

CAMPBELL, E. D., Captain, Engineer Officers' Reserve Corps*

CARLSSON, CARL A. V., Ordnance Engineer, Navy Dept., Ordnance Office, Navy Yard, Washington, D. C.

CATTELL, WILLIAM A., Major, Engineer Officers' Reserve Corps*

CHURCH, ELIHU CUNNINGHAM, Seventh Infantry, New York.

CLUETT, SANFORD L., Major, Signal Corps, New York National Guard.

COMSTOCK, CHARLES W., Second Lieutenant, Field Artillery, National Guard, Colorado.

COOKE, STANLEY S., Private, Troop D, 1st Squadron Cavalry, Colorado National Guard.

COYLE, A. M., Mechanical Engineer, Coast Defense, Board of Engineers, U. S. A.

CRUIKSHANK, BARTON, Captain, R. L., First Cavalry, National Guard, New York.

CURTIS, GREELY S., Lieutenant, Junior Grade, 10th Deck Division, Massachusetts Naval Militia.

DAVIS, FRANCIS P., Second Lieutenant, Coast Artillery Corps, New York National Guard. Assigned to [illegible] Co., 8th C. D. C.

DAVIS, JAMES H., Second Lieutenant, Coast Artillery Corps, New York National Guard. Assigned to 33d Co., 8th C. D. C.

DELEMOS, SIDNEY R., Captain, Engineer Officers' Reserve Corps.

DEWOLF, ROGER D., Lieutenant, 7th Division, 3d Battalion, Naval Militia, New York.

DOTY, PAUL, Commissary General, rank of Brigadier General, Minnesota National Guard.

DOTY, PAUL, Major, Engineer Officers' Reserve Corps.

DOYLE, M. A., Second Lieutenant, Engineers, U. S. Coast Guard.

EATON, P. B., Second Lieutenant, Engineers, U. S. Coast Guard.

ELMES, CLYDE C., Captain, Engineer Officers' Reserve Corps.

FITZGERALD, EDWARD T., Captain, 2d Battalion, Naval Militia, New York.

FRY, ALFRED BROOKS, Captain, Naval Militia and Engineers' Reserve List, U. S. N.

FULLER, RAY W., Captain, Company A, Engineers, U. S. and Penna.

GILLIS, H. A., Major, Engineer Officers' Reserve Corps.

GREEN, F. W., Captain, Engineer Officers' Reserve Corps.

GREGORY, WILLIAM B., Major, Engineer Officers' Reserve Corps.

GUNBY, FRANK M., Captain, Artillery Engineer, C. A. C., Massachusetts National Guard.

HALL, HARRIS F., Captain, Company M, 6th Infantry, Illinois National Guard.

HERBERT, J. S., Captain, Engineer Officers' Reserve Corps.

HILL, FRANCIS L., Company H, First Virginia Regiment Volunteers.

HOLMES, URBAN T., Commander, U. S. N., Navy Department, Washington, D. C.

HOLMGREN, F. C., Automobile expert, Rock Island Arsenal, Rock Island, Ill.

HUBBELL, LYMAN P., Captain, Quartermaster Corps, 74th New York Infantry, National Guard.

HUNT, LEIGH, Lieutenant, Machine Gun Company, 1st Kansas Infantry, Eagle Pass, Texas.

HUTCHENS, EDWARD, Captain, Engineer Officers' Reserve Corps*

INGHAM, HOWARD M., [illegible] 1st M[illegible] of Englewood, N. J.

IRELAND, MARK L., Captain, [illegible]

JAMIESON, CHAS. C., Major, [illegible] U. S. Army [illegible]

JENKS, GLEN F., Major, [illegible] U. S. A., [illegible] Ordnance Depot, [illegible]

JOHNSTONE, EDWARD J., Lieutenant, Junior Grade, Naval Militia.

JUNKERSFELD, PETER, Major, Engineer Officers' Reserve Corps*

KATTE, E. B., Major, Engineer Officers' Reserve Corps.

KESSLER, ARMIN GEORGE, Lieutenant, Senior Grade Naval Militia, Erie, Pa.

KILPATRICK, JOHN D., Major, Quartermaster Corps, N. J.

KING, CHARLES G. A., Lieutenant Commander, Illinois Naval Reserve.

KINGSTON, ARTHUR, Lieutenant, 4th Regiment, U. S. Marine Corps.

KRAUS, SIDNEY M., Lieutenant (J. G.), U. S. N., U. S. S. Sampson.

LAMONT, CLARENCE B., Captain, Engineer Officers' Reserve Corps.

LARSEN, CHARLES, First Lieutenant, Engineer Officers' Corps*

LINCOLN, PAUL M., Captain, Engineer Officers' Reserve Corps.

McLEAN, ROBERT W., First Lieutenant, Engineer Officers' Reserve Corps.

McMUNN, WILLIAM N., Commander, Illinois Naval Reserve.

MANSFIELD, JULIAN B., Captain, Infantry and Artillery, Reserve.

MARTIN, KINGSLEY G., Private, Class B, Depot Battalion, 22d Regiment of Engineers.

MAXFIELD, HOWARD H., Captain, Engineer Officers' Reserve Corps.

MERSHON, R. D., Major, Engineer Officers' Reserve Corps.

MILLER, MARTIN NIXON, Chief Building Inspector, Frankford Arsenal, Ordnance, War Dept., U. S. A.

MOON, HARTLEY A., Major, Infantry, 4th Battalion, 3d Regiment.

NEWCOMB, ROBERT S., Captain, Coast Artillery Corps, New York National Guard.

NEWTON, GUY D., Major, Engineer Officers' Reserve Corps*

NORRIS, ALEX. MURDOCH, Ensign, Engineer Duties, Maryland Naval Militia.

OATLEY, HENRY B., Naval Militia.

OHMER, JOHN F., JR., First Lieutenant and Battalion Adjutant, 3d Ohio Infantry.

OSGOOD, WENTWORTH H., Lieutenant, U. S. N., U. S. S. Chester.

OTTO, HENRY S., Private, Squadron A, New York National Guard.

PARKER, CHARLES H., Captain (retired), Massachusetts Naval Militia.

PELLY, JOHN F., Battery A, First Field Artillery, Pennsylvania National Guard.

PELLY, JOHN F., Corporal, Battery A, First Field Artillery, Pennsylvania.

PELOT, JOSEPH H., Major, Ordnance Dept., U. S. A., Frankford Arsenal, Philadelphia.

RATHJENS, G. WILLIAM, Captain, Engineer Officers' Reserve Corps*

REIMER, ARTHUR A., Captain, Engineer Officers' Reserve Corps.

RICHARDSON, EDWARD BRIDGE, Captain, Battery A, Massachusetts Field Artillery.

ROBINSON, WILLIAM, Second Lieutenant, Engineer Officers' Reserve Corps*

SANDSTROM, C. O., Captain, Company L, 3rd Regiment, Mo., Laredo, Texas.

SCHLANK, ELIAS, Private, Sanitary Division, 7th N. Y. Infantry, National Guard.

SCHNEIDER, G. A., First Lieutenant, Engineer Officers' Reserve Corps.

SCOTT, ROSSITER STOCKTON, Corporal, Battery A, Maryland National Guard.

SIMPSON, COLIN C., JR., Private, Depot Battalion, 7th New York Infantry.

SMITH, ALBERT S., Captain, Engineer Officers' Reserve Corps.

SMITH, WILLIAM WALKER, Lieutenant, U. S. N., Pittsburgh, Pa.

STARK, W. E., Second Lieutenant, Engineer Officers' Reserve Corps.

STEEL, REGINALD A., Corporal, Company A, 22nd Corps of Engineers, National Guard, New York.

STRAHLMANN, O. E., Aeronautical Engineer, U. S. Army Signal Corps.

SUMMERS, DANIEL, Second Lieutenant, Engineer Officers' Reserve Corps*

SUTTON, FRANK, Major, Engineer Officers' Reserve Corps.

SWAN, JOHN J., Captain, Engineer Officers' Reserve Corps.

SWIFT, JOHN B., Lieutenant, Company E, 1st Battalion, Illinois Engineers.

TAYLOR, DONALD F., Private, Squadron A, Machine Gun Battery, New York Division.

TAYLOR, L. B., Torpedo Engineer, U. S. Naval Torpedo Station, Newport, R. I.

TOLTZ, MAX, Major, Engineering Corps, Minnesota National Guard.

TREAT, SIDNEY W., Sergeant, 7th Infantry N. G. U. S.

TRUSCOTT, HAROLD S., Captain commanding Co. I, 3d Batt., 4th Inf. Reg., National Guard of Hawaii.

TURNER, ROBERT T., JR., Gunner, N. Y. Training Battery.

VIETS, HARRY A., Sergeant, 13th Coast Defense Command, National Guard, New York.

WAGNER, CHARLES FRANCIS, Captain, Engineer Officers' Reserve Corps.

WAITT, ARTHUR M., Major, Engineer Officers' Reserve Corps.

WESTERVELT, W. I., Major, U. S. A., U. S. Government, Washington, D. C.

WHITLEY, FREDERIC N., Major, First Battalion, New York Engineers.

WHITLOCK, E. H., Major, Engineer Officers' Reserve Corps*

WHITNEY, HERBERT A., Assistant Battery Commander, Coast Artillery, National Guard.

WHITTED, T. B., Captain, Engineer Officers' Reserve Corps*

WILDER, C. W., First Lieutenant Engineer Officers' Reserve Corps.

WILSON, HENRY C., Major, 8th Coast Defense Command, National Guard, New York.

WOOD, HORATIO N., First Lieutenant of Engineers, U. S. Coast Guard, U. S. Cutter Morrill, Detroit, Mich.

WOODRUFF, CLARENCE A., Second Lieutenant, Connecticut Coast Artillery Corps.

YORK, HERBERT W., Lieutenant Commander, Naval Militia, New York.

ZIMMERMAN, OLIVER B., Captain, Engineer Officers' Reserve Corps.

* Acceptance of commission pending at date of latest list from War Department

THE SPRING MEETING AT CINCINNATI

THE record of the Spring Meetings of the Society brings back the most pleasant recollections of good fellowship, inspiration and renewed interest in the affairs of the Society to those who have been fortunate in being present at these meetings. It also calls to mind many gracious hospitalities extended to the Society by friends of engineers in every part of the country in which these meetings have been held.

The entertainment part of the program ot the Spring Meeting of The American Society of Mechanical Engineers, to be held in Ohio, May 21 to 24, if carried out as it has been planned by the Cincinnati Local Committee, will make this meeting the most enjoyable one ever held by the Society. The Committee has excelled itself in providing novel and attractive features for this part of the program.

In this anticipation of the good time in store for members and guests attending the meeting, we must not lose sight of the fact that there are serious matters to be considered, and that some of the topics to be presented and discussed at the professional sessions are of vital national importance at this time. The Technical Section of this issue of The Journal is devoted to the papers to be given at these sessions.

A complete program of the meeting is published below. Full information was given in the last issue of The Journal regarding transportation and fares and hotels, and nothing remains now but for members to complete their own arrangements for being present with their guests at the Hotel Sinton, in Cincinnati, on the morning of Monday, May 21.

Below are also given brief biographical notes of the authors of the papers.

Authors of the Papers

J. F. Barkley has been connected with the U. S. Bureau of Mines for about four years, working on fuel problems concerning boiler-room practice, particularly the transmission of heat from the gases of combustion to the boiler water. He has also spent some time with the Westinghouse Electric and Manufacturing Co., partly on heat problems. There are several government publications along the lines of his paper.

Harry L. Coe is vice-president of Harpham, Barnes, Stevenson & Coe, Inc., production engineers of Boston. For the past ten years he has specialized in general production engineering work, factory organizations, types of management and machine production. He has had charge, for the past two years, of the projectile departments of the Vermont Farm Machine Company and the Consolidated Car-Heating Company, manufacturing 3-in. shrapnel.

Adolph L. De Leeuw speaks from a very extended experience, having been designing engineer with the Niles Tool Works Company, mechanical engineer with the Cincinnati Milling Machine Company, and at present is mechanical engineer with the Singer Manufacturing Company. He has written quite a number of papers on the important subject of metal cutting and metal cutters.

John R. Du Priest is at present head of the Mechanical Engineering Department of the University of Idaho, Moscow, Idaho. He is a specialist in gas-engine work, having served as chief engineer with the Columbus Machine Company where complete power plants for pumping, lighting and manufacturing were turned out under his direction. He is the inventor of various new designs in gas and oil-engine machinery.

Otto P. Geier became associated with The Cincinnati Milling Machine Co. three years ago to organize an Employee's Service department. He was formerly superintendent of the Department of Charities and Correction at Cincinnati, and has given a great deal of attention to the problems of public health work. He is chairman of the section on Preventive Medicine of the American Medical Association, and chairman of the Health Service Section of the National Safety Council.

Henry J. Guild is superintendent of the paper mills of the Eastern Mfg. Company, Bangor and Lincoln, Maine. He has been associated with the development of scientific methods from the beginning and is continuing this development.

Harry V. Haight is at present chief engineer of the Canadian Ingersoll-Rand Company, Ltd., Sherbrooke, Quebec, having for many years served in a similar capacity with the Canadian Rand Drill Company. He has made a specialty of compressed-air machinery, including designing of air compressors, rock drills, coal cutters, compressed-air locomotives, haulage plants and general pneumatic tools.

Keppele Hall has made an intensive study of the Taylor system and in practice as a consulting engineer, associated with Sanford E. Thompson, Mem.Am.Soc.M.E., specializes in the same subject. In this particular line of work he has been employed for the last three years as a resident engineer of the Eastern Manufacturing Company's paper mill.

Arthur L. Humphrey is at present vice-president and general manager of the Westinghouse Air Brake Co. He has had a very wide experience in railroad engineering, having held executive positions with the Union Pacific, Southern Pacific, Colorado Midland, Colorado Southern and other railroads. He has made a specialty of improved shop facilities and modern appliances for economical manufacturing operations.

Horace Judd has been connected with The Ohio State University for the past fifteen years. From 1902 to 1910 he was assistant professor and since 1910 has been associate professor of experimental engineering. During that time his work has been chiefly along the lines of gas, hydraulic, and steam engineering, with more attention during the past few years to hydraulic subjects, especially to the flow of fluids through pipes and orifices.

F. G. Kent is at present works manager of the Lodge & Shipley Machine Tool Company. He was formerly for four years general superintendent of manufacturing with the Pierce-Arrow Motor Car Company. Before that he was associated with The Goodman Manufacturing Company, manufacturers of electrical mining machinery, as works manager. He has a wide and varied experience in machine shop practice, and is a specialist on the subject of organization.

Henry Kreisinger has been connected with the Government fuel investigation for the last thirteen years. He has made a large number of steaming tests of many kinds of fuels and with various boiler equipments. He is now in charge of the fuel-efficiency laboratory of the U. S. Bureau of Mines. His interest is principally given to the study of combustion of coal and heat transmission in engineering problems. He is a co-author of a number of government publications on these subjects.

William O. Lichtner is a member of the firm of Thompson & Lichtner, Consulting Engineers. He specializes in advice on management conditions and on the introduction of scientific methods of management in construction and industrial operations.

Charles Edward Lucke has carried out a great variety of investigations, both scientific and commercial, and has published numerous papers and books on engineering subjects, especially gas-engine design. As head of the mechanical-engineering department at Columbia University he organized new courses and developed new methods of instruction. He has also acted as consulting engineer to various important industrial concerns.

[illegible] W. M[illegible] [illegible] professor of [illegible] engineering at the Ohio State University. Previous to that [illegible] for six years a member of the staff of the Engineering Experiment Station of the University of Illinois. In both of these positions he had devoted [illegible] time to [illegible] study, largely experimental, of [illegible] and [illegible] machinery.

Charles M[illegible] has been connected with the Cincinnati Planer Company for the past [illegible] years, serving the first eleven years as chief designer and superintendent and the last five [illegible]. He has specialized in the [illegible].

Charles B. N[illegible] has been connected with Robert W. Hunt & Co. for the past seven years, having charge during the latter four years of the inspection of general engineering materials. He has given particular attention recently to the inspection and testing of [illegible] classes of artillery, equipment and other important munitions [illegible] supplied the European Governments by this country.

[illegible] E. Otterson is at present first vice-president and general manager of the Winchester Repeating Arms Company, New Haven, Conn. He graduated from the Naval Academy and served as an officer in the Navy. He was also graduated as Master of Science by Massachusetts Institute of Technology and served as Naval Constructor in the United States Navy.

Victor B. Phillips has been connected since 1911 with The Cleveland Railway Company which has studied very thoroughly the matter of power policy. The company has investigated at great length questions of purchased-power rates and the rehabilitation of old plants or the construction of new plants, and as a result enjoys the lowest purchase rates for steam-generated power known in this country. As assistant to the Superintendent of Power, Mr. Phillips in the last two years has devoted himself almost entirely to the above problems.

Herman Schneider is Dean of the College of Engineering, University of Cincinnati. He devised and put into operation the coöperative scheme of education whereby students spend alternating bi-weekly periods in seventy-five industrial, construction, and transportation concerns, and at the Engineering College of the University of Cincinnati. The course has been in operation eleven years, and there are five hundred students enrolled in the work.

Sanford E. Thompson is a consulting engineer and member of the firm of Thompson & Lichtner, Consulting Engineers. He has advised on many projects both in lines of construction and investigation and shop management, acting at the present time as consulting engineer in the introduction of scientific methods of management for various concerns.

Frederick A. Waldron has had experience with the Brown & Sharpe Manufacturing Co., Beaman & Smith, and the Yale & Towne Manufacturing Co. With the last mentioned company he worked his way up to the position of superintendent. He has been practising as an industrial engineer for some years, and is chairman of the Sub-Committee on Industrial Buildings of the Society.

Edward T. Walsh has had experience as construction engineer and as mechanical engineer of the Workmen's Compensation Service Bureau. He has been engaged in industrial engineering for more than ten years. He is at present chief engineer of the Canadian Car and Foundry Company, Ltd., in which capacity he has been brought in close touch with the Russian Technical Bureau and Russian Inspection.

S. H. Weaver has been connected with the Schenectady works of the General Electric Company for the past thirteen years. For the greater part of that period he has supervised the mechanical-stress calculations for the varied electrical apparatus that company produces.

Frank O. Wells has been connected with Wells Brothers Co. since 1876, and has been president of the Greenfield Tap and Die Corporation since its organization. He has devoted a great deal of his time during the past several years towards instituting the United States Standard thread in place of the so-called V-thread. Such success as has been achieved towards this end is largely due to the efforts of Mr. Wells, not only in his individual capacity on many occasions, but also as Chairman of the Sub-Committee of the A. S. M. E., to which Committee was referred the matter of standardization of screw thread tolerances. As a step towards preparedness, the Government, at the suggestion of Mr. Wells, and through his personal efforts and the information he placed at their disposal, has done a great deal to standardize and equip private plants with all gages necessary to manufacture munitions and arms.

Lucien J. Yeomans is practising in Chicago as an industrial engineer and is also a patent attorney. He has had wide experience as a production engineer, and specializes in shop organization and methods of cost reduction. He is manager of the Amalgamated Machinery Corporation and patentee of the machine tools manufactured by them.

John Younger is chief engineer of the Truck Division of the Pierce-Arrow Motor Car Company, and has been so for the past five and one-half years. He has specialized in motor-truck design, motor-truck and road-vehicle transportation for the past twelve years.

Enlargement of Engineering Survey Section

In the Engineering Survey Section of this issue of The Journal is taken another step in the policy of the Publication Committee to develop The Journal along lines of increasing usefulness.

From now on the Survey will review important engineering events, as well as the leading articles in technical periodicals, which has heretofore been its distinguishing feature. The new department will be devoted exclusively to professional matters and will include reports of the meetings of other engineering societies, synopses and lists of researches conducted by various laboratories, besides brief articles and items having a more strictly news value.

Engineers are busy men. Few have time to more than keep in touch with the developments in their own specialized fields, and too often in respect only to trade conditions. It is hoped by the Publication Committee that the new development in the Engineering Survey will enable its readers to follow more readily the progress in the various fields in which they may be interested.

Request for January Issues

The demands for copies of the January 1917 issue of The Journal, which contains a full account of the 37th Annual Meeting, have now exceeded the supply, and this issue is temporarily out of stock. Requests for copies are still being made, however, and members who do not desire to preserve permanently their copy of the January Journal are requested to return it to the Secretary, who will remit postage and cost.

Presentation of John Fritz Medal

The John Fritz Medal was awarded in January, 1917, to Dr. Henry Marion Howe, for his "investigations in metallurgy, especially in the metallography of iron and steel."

The presentation ceremonies will take place in the Auditorium of the Engineering Societies Building, at 8:30 p. m., on May 10.

Ambrose Swasey, chairman of the John Fritz Medal Board of Award, will preside and addresses will be delivered by Dr. Rossiter W. Raymond, secretary emeritus of the American Institute of Mining Engineers, Dr. Ira N. Hollis, Presi-

SPRING MEETING PROGRAM

Cincinnati, May, 21-24, 1917

Monday, May 21

10.00 a.m. Opening of headquarters and registration at Hotel Sinton.
2.00 p.m. Council Meeting.
During the afternoon there will be trips to the shops of the city and an inspection visit to the hospital
8.00 p.m. Informal Reception.

Tuesday, May 22

10.00 a.m. Business Meeting, followed by Professional Sessions.

MACHINE SHOP SESSION

A Foundation for Machine Tool Design and Construction, A. L. DeLeeuw.
Machine Shop Organization, Fred G. Kent.
Metal Planers and Methods of Production, Charles Meier.

GENERAL SESSION

Tests of Uniflow Steam Traction Engines, F. W. Marquis.
Relation of Efficiency to Capacity in the Boiler Room, Victor B. Phillips.
Radiation Error in Measuring Temperature of Gases, Henry Kreisinger and J. F. Barkley.
Development of Scientific Methods of Management in a Manufacturing Plant, Sanford E. Thompson and Associates.
Disk Wheel Stress Determination, S. H. Weaver (by title only).

Excursion for the ladies to Rookwood Pottery and the Art Museum.

2.30 p.m. Joint Session with National Machine Tool Builders' Association, with two addresses:
The Trend in Engineering Training, Dean Herman Schneider.
The Human Potential in Industry, Dr. Otto P. Geier.

Trolley ride for the ladies to Fort Thomas.

8.15 p.m. Smoker for members of the Society and of the National Machine Tool Builders' Association.
Reception for the Ladies.

Wednesday, May 23

10.00 a.m. FIRST MUNITIONS SESSION.

Opening remarks by Major E. D. Bricker, Ordnance Department, Frankford Arsenal, and Lieutenant T. S. Wilkinson, Jr., U. S. N. Bureau of Ordnance.
Munitions Contracts and Their Financing, Frederick A. Waldron.
Organizing for Munitions Manufacture, Arthur L. Humphrey.
Organization for Munitions Manufacture, Harry L. Coe.
Procuring Special Machines for Munitions Manufacture, H. V. Haight.
Practical War-Time Shell Making, Lucien I. Yeomans.

Trip for ladies through leading stores and visit to skyscraper.

2.00 p.m. Boat ride to Fern Bank Dam or Water Works.
8.30 p.m. Informal Dance.

Thursday, May 24

10.00 a.m. Simultaneous Sessions.

SECOND MUNITIONS SESSION

The Design of Munitions for Quantity Manufacture, J. E. Otterson.
Procuring Materials for Munitions, C. B. Nolte.
Limits and Tolerances for the Manufacture of Munitions, A. W. Erdman.
Gages and Small Tools, F. O. Wells.
The Importance of Intelligent Inspection in Munitions Manufacture, E. T. Walsh.

GAS POWER SESSION

The Problem of Aeronautical Engine Design, C. E. Lucke.
Test of a Motor Fire Engine, Horace Judd.
Design of Motor Truck Engines for Long Life, John Younger.
Relation of Port Area to the Power of Gas Engines and its Influence on Regulation, J. E. DuPriest.

INDUSTRIAL SAFETY SESSION

Proposed Code of Safety Standards for Industrial Ladders.

In the afternoon, Motor Car Ride to Mt. Storm, U. C. Observatory, Ault Park, visits to Machine Plants.
On Friday, for those who remain over, there will be an opportunity for trips to Fort Ancient, Mammoth Cave or to Lexington.

dent of our Society, and Judge Elbert H. Gary, chairman of the Board of the United States Steel Corporation.

Professor Albert Sauveur, chairman of the Board at the time the award was made, will present the medal and the ceremonies will conclude with the response of Dr. Howe.

The John Fritz Medal is awarded from time to time for notable scientific or industrial achievement, and is provided for in a fund subscribed in memory of the great engineering pioneer, John Fritz. The award of the medal is made by a permanent Board of Award composed of four members from each of the four societies: the American Society of Civil Engineers, the American Institute of Mining Engineers, The American Society of Mechanical Engineers, and the American Institute of Electrical Engineers.

The members of the board for 1917 are:

A. S. C. E.	A. I. M. E.
George F. Swain	E. Gybbon Spilsbury
Charles Warren Hunt	Charles F. Rand
Charles D. Marx	Christopher R. Corning
Clemens Herschel	Benjamin B. Thayer
A. S. M. E.	**A. I. E. E.**
Ambrose Swasey	C. O. Mailloux
John A. Brashear	Paul M. Lincoln
Frederick R. Hutton	John J. Carty
John R. Freeman	Harold W. Buck

Members of the engineering societies and others interested, including ladies, are cordially invited to be present at the presentation ceremonies.

Committee of Arrangements
C. O. Mailloux,
Charles Warren Hunt,
John R. Freeman,
E. Gybbon Spilsbury, *Chairman.*

Fares to Spring Meeting

Members of the Society and their friends visiting Cincinnati to attend the Spring Meeting from California, Nevada, Washington, Oregon and British Columbia may avail themselves of the nine-months' excursion fares which are in effect daily from these States to Chicago, St. Louis, Memphis, New Orleans and other eastern terminals of transcontinental lines. They can then rebuy tickets to their final destination, at fares in effect from Transcontinental Passenger Association Eastern Terminals. Thus, nine-months' excursion fares approximate two cents per mile in each direction, or about one fare and 1/3 for round trip.

Full particulars of these reduced fares may be obtained from the Transcontinental Passenger Association, 608 South Dearborn St., Chicago, Ill.

Death of Mr. James Forrest

Mr. James Forrest, honorary secretary of the Institution of Civil Engineers of Great Britain, died on March 1, 1917.

Mr. Forrest was born in London Nov. 30, 1825. In his sixteenth year he was articled to Edward and John Manby, civil engineers, in Westminster. Later he became associated with Charles Manby, secretary of the Institution of Civil Engineers. About 1852, after an interim of a few years on railway construction, he became assistant secretary to the Society of Arts under Mr. George Grove. He returned again to the staff of the Institution of Civil Engineers, and in 1860 was appointed secretary. Following his appointment the Institution immediately took on new life, for during his tenure of office both the roll of membership and the income increased tremendously. To perpetuate the memory of his long service for the Institution an endowment fund was raised by the members in 1891 and, in accordance with Mr. Forrest's wish, was devoted to the founding of the James Forrest Lectureship.

His death is mourned by members of kindred societies on both sides of the Atlantic, and many of our members will long cherish memories of the unfailing courtesies and attentions paid them by Mr. Forrest when they visited the headquarters of the Institution in London.

Spring Meeting of New Haven Section

The Spring meeting of the New Haven Section on April 19 was a successful and well-attended affair. As is the custom with this Section, two sessions were held, in Mason Laboratory, Sheffield Scientific School, dinner being served in the interval between at the Yale Dining Club.

Henry B. Sargent, Mem.Am.Soc.M.E., Chairman of the New Haven Section, presided at the afternoon session, when Herbert C. Nickerson, Chief Engineer of Pumping Stations, New Haven Water Company, presented an interesting paper on Water Works Pumping Engines, in which he gave particulars of the various types of plants that had been installed by the company since its organization in 1861. Following this, excursions were made by automobile to the large pumping stations at Lake Whitney and Lake Saltonstall, where opportunity was afforded to inspect all but the earliest engines described by Mr. Nickerson.

At the evening session, J. Arnold Norcross, Mem.Am.Soc.M.E., who acted as chairman, voiced the regret of the Section and its guests at the inability of Dr. Ira N. Hollis, President Am.Soc.M.E., to be present and address them, owing to exigencies arising from the war situation. He then introduced F. F. Nickel, Mem.Am.Soc.M.E., of the engineering department of Henry R. Worthington, Harrison, N. J., who read a paper on The Development of the Centrifugal Pump, which was profusely illustrated with lantern slides, and which dealt with the various types of pumps of this class, their special uses and advantages, the interpretation of their characteristics, and with methods employed to obviate end thrust, and other design problems. Some interesting points on fire pumps were brought out in the limited time available for the discussion of the paper.

The second paper of the evening, by H. M. Chase, Mem. Am.Soc. M. E., of the engineering department of the Deane Works, Holyoke, Mass., on Pumping Machinery for Industrial Purposes, was devoted to the reciprocating type of pump, its mechanisms, and its adaptation to the special requirements of a wide range of industries. This paper was also abundantly illustrated.

Among the audience were many members of the Winchester Engineering Club, which society had postponed a meeting of its own in order to take advantage of the program offered by the New Haven Section.

The Hardness of Metals. Sir Robert A. Hadfield, Mem.Am. Soc.M.E., has placed in the hands of the British Institution of Mechanical Engineers a sum, the interest on which may be awarded as a prize for the description of a new and accurate method of determining the hardness of metals, especially of metals of a high degree of hardness.

Particulars regarding the competition may be obtained by addressing the secretary of the Institution, Great George Street, Westminster, London.

CANDIDATES FOR MEMBERSHIP

TO BE VOTED ON AFTER JUNE 10, 1917

THE American Society of Mechanical Engineers is an organization for mutual service of over 7800 engineers and associates coöperating with engineers. The membership of the Society comprises Honorary Members, Members, Associates, Associate-Members and Juniors, all elected by ballot of the Council. Application for membership is made on a regular form furnished by the Secretary which provides for a statement of the standing and professional experience of the applicant and requires references from voting members personally acquainted with the applicant. The requirements for admission to the various grades will be furnished upon request.

Below is the list of candidates who have filed applications for membership since the date of the last issue of The Journal. These are classified according to the grades for which their ages qualify them, and not with regard to professional qualifications, i.e., the ages of those under the first heading place them under either Member, Associate or Associate-Member, those in the next class under Associate-Member or Junior, and those in the third under Junior grade only. Applications for change of grading are also posted.

The Membership Committee, and in turn the Council, urge the members to scrutinize this list with care and advise the Secretary promptly of any objections to the candidates posted. All correspondence in this regard is strictly confidential. Unless objection is made to any of the candidates by June 10, 1917, and providing satisfactory replies have been received from the required number of references, they will be balloted upon by the Council. Those elected will be notified about July 15, 1917.

NEW APPLICATIONS

FOR CONSIDERATION AS MEMBER, ASSOCIATE OR ASSOCIATE-MEMBER

California

BOND, JOHN M., Assistant Plant Engineer, The Holt Manufacturing Co., Stockton

GOESER, EDWIN W., Chief Engineer, Union Tool Co., Torrance

Connecticut

BUXBAUM, WILLIAM, Production Superintendent, Tool Department, Winchester Repeating Arms Co., New Haven

FRAUENBERGER, CARL F., Planning Supervisor, Winchester Repeating Arms Co., New Haven

KENYON, FREDERICK G., Group Head, Tool Designing Department, Remington U. M. C. Co., Bridgeport

McQUILLAN, JOHN, Mechanical Engineer, Remington Arms U. M. C. Co., Bridgeport

VAN YORX, JOHN H., JR., Manager of Foundry, Bullard Machine Tool Co., Bridgeport

WILSON, HOWARD B., Efficiency Engineer, New Departure Mfg. Co., Bristol

District of Columbia

GILLIS, IRVIN V., Commander (retired) U. S. Navy, Representing Bethlehem Steel Co. in China

Illinois

KNAPP, LELAND G., Efficiency Engineer, Emerson Co., Efficiency Engineers, Chicago

PITT, ALMA A., President, The Pitt Engineering Co., Chicago

Indiana

BURRELL, BENJAMIN S., Master Mechanic, Inland Steel Co., Indiana Harbor

COREY, DAVID A., Executive Engineer, S. F. Bowser & Co., Inc., Fort Wayne

NOLAND, RALPH W., Instructor in Machine Design, Purdue University, Lafayette

Maryland

FOX, HARRY K., Chief Draftsman, Motive Power Department, Western Maryland Railway Co., Hagerstown

Massachusetts

COGSWELL, LESTER W., Engine Designer, Kinney Manufacturing Co., Boston

DAVIS, SIDNEY L., Production Engineer, Bausch Machine Tool Co., Springfield

KNIGHT, FREDERICK D., Superintendent of Construction, Stone & Webster Engineering Corp., Boston

MONTGOMERY, WILLIAM J., Instructor in Machine Work, Brockton High School, Brockton

WILLARD, FRANK H., Assistant General Manager, Graton & Knight Manufacturing Co., Worcester

Michigan

GALLAGHER, WILLIAM H., JR., Electrical-Mechanical Engineer, Wolverine & Mohawk Copper Mining Co., Kearsarge

ROWEN, JOHN H., Commander (Retired) U. S. Navy, and Member of Faculty of Engineering College, University of Michigan, Ann Arbor

SINTZ, CLAUDE, Engineer, Detroit

Minnesota

POLLARD, LAWRENCE E., Sales Engineer, L. E. Pollard Co., Minneapolis

RUFF, DE WITT C., Vice-President, Fire Brick Construction Co., Minneapolis

New Jersey

KOTTENBASH, ERNEST E., Chief Engineer, Schafer Ball Bearings Co., Inc., Hawthorne

MATTHEWS, JOHN B., Marine-Power Engineer, Samuel L. Moore Sons Corp., Elizabeth

MOUNT, RALPH H., Manager, The Okonite Co., Passaic

New York

ABELS, ALOYSIUS J., President, A. J. Abels Co., Inc., Buffalo

BALDWIN, ARTHUR J., Publisher, Vice-President, McGraw-Hill Publishing Co., Inc., New York

CONNER, WILLIAM W., Engineer, Eastman Kodak Co., Rochester

CORLISS, WILLIAM J., State Locomotive Boiler Inspector, Public Service Commission, Albany

DIETER, WILLIAM, Torpedo Engineer, E. W. Bliss Co., Brooklyn

DIVINE, BRADFORD H., President, Divine Brothers Co., Utica

KEARFOOT, WILLIAM D., Marine Engineer, New York

LACY, ROBERT, Estimating Engineer, Otis Elevator Co., New York

MOEN, LECLANCHE, President, C. W. Hunt Co., Inc., New York

WATKINS, ARTHUR M., Secretary, Inter-Continental Machinery Corp., New York

North Carolina

HARDESTY, GEORGE H., Engineer in Charge, State Hospital, Goldsboro

Ohio

BICKETT, CHARLES A., President, The Bickett Machine & Mfg. Co., Cincinnati

CHRYST, WILLIAM A., Chief Engineer, Dayton Engineering Laboratories Co., Dayton

JUPP, ALFRED J., Sales Director, The Lunkenheimer Co., Cincinnati

LYON, GEORGE R., Vice-President, The Power Equipment Co., [illegible]

STONE, JULIUS F., President, The Seagrave Co., Columbus

WALTER, FRANK L., Master Mechanic, Dayton Engineering Laboratories Co., Dayton

Pennsylvania

BRESSLER, J. WALTER, Metallurgist, Tacony Steel Co., Tacony

DUNN, J. JAY, General Superintendent, Shelby Steel Tube Co., Ellwood City

FORREST, JAMES, Assistant General Foreman, Baldwin Locomotive Works, Philadelphia

McNARY, JAMES E., Staff Engineer, Lubrication Division, The Texas Co., Pittsburg

SAYLOR, JOHN R., Proprietor, Pottstown Machine Co., Pottstown

[illegible] Field Engineer,
[illegible] Philadelphia
WANDLESS, [illegible] W., [illegible] Supervisor,
[illegible] Co., Eddystone

Tennessee

CAROTHERS, [illegible] G., Senior Mechanical Engineer,
Interstate Commerce Commission,
[illegible] Chattanooga
DANIELS, [illegible] H., [illegible]
Walsh & Weidner Boiler Co., Chattanooga

Wisconsin

MANHEKE, [illegible]
[illegible] Engineering & Mfg. Co., Milwaukee
MILBRATH, [illegible] Engineer,
[illegible] Mfg. Co., Milwaukee
ELVERT, [illegible], Assistant Engineer,
[illegible] Mfg. Co., West Allis

Canada

JOHNSON, [illegible], Assistant General Sales Manager,
Armstrong Whitworth of Canada, Ltd., Montreal
KINGSTON, JAMES S., Heating and Ventilating Engineer,
Department of Public Works, Ottawa

Italy

FERRERO, MICHELE, President of
Società Italiana Macchine Utensili, Milano

Scotland

MITCHLEY, JOHN W., Mechanical and Chemical Engineer,
Ministry of Munitions, Dornock, N. B.

FOR CONSIDERATION AS ASSOCIATE MEMBER OR JUNIOR

Alabama

ROBERTS, ARTHUR M., Assistant Superintendent,
Alice Furnace, Tennessee Coal, Iron & R. R. Co., Birmingham

California

LAMB, HAWTHORNE M., Senior Mechanical Engineer,
Interstate Commerce Commission, San Francisco

Illinois

DRAKE, ROBERT W., Steam and Electrical Engineer,
International Harvester Co. of N. J., Chicago
GOENSCH, OTTO, Department Head,
Western Electric Co., Inc., Chicago
STUEBING, ALBERT F., Western Mechanical Editor,
Railway Age Gazette, Chicago
WHITESIDE, VICTOR, Testing Engineer,
Western Electric Co., Chicago

Massachusetts

PETRIE, ELMER H., Mechanical Engineer,
Fred T. Ley Co., Inc., Springfield
WILKINSON, JAMES, Consulting Engineer,
General Electric Co., Pittsfield

Montana

WOHLENBERG, WALTER J., Assistant Professor of Mechanical Engineering, University of Montana, Bozeman

New Jersey

STERN, JOSEPH H., Assistant Engineer,
Aeolian Co., Garwood

New York

BEINECKE, FRITZ W., Supervisor of Automobile Equipment,
The Texas Co., New York
CHANDLER, HEMAN W., Draftsman Maintenance Department,
American Locomotive Co., Dunkirk
HILDRETH, KENNETH E., Chief Electrician,
New York & New England Cement & Lime Co., Hudson
HINRICHSEN, ARTHUR F., Works Manager,
Slocum, Avram & Slocum Laboratories, Inc., New York
LEACH, EDGAR J., Engineer,
Curtiss Aeroplane & Motor Corp., Buffalo
LEISENRING, FRANK S., President,
Mechanical Specialties Co., New York
RAMSEY, JAMES F., Lubricating Engineer,
Vacuum Oil Co., New York
WACHENBERG, LEWIS, Technical Assistant to Superintendent,
Arbuckle Bros., Brooklyn
WELSH, MILFORD G., Superintendent,
Mohawk Gas Co., Schenectady

North Carolina

SHEARER, DAVID R., Consulting Engineer, Shulls Mills

Ohio

BRUSSEL, JOHN W., Supervisor of Machining,
Dayton Engineering Laboratories Co., Dayton
HASKELL, ALLAN G., Sales Engineer,
Champion Spark Plug Co., Toledo

Oklahoma

WOOBANK, WILFRED, Sales Engineer,
Worthington Pump & Machinery Corp., Tulsa

Canada

BROOKS, CHARLES E., Superintendent Motive Power,
Grand Trunk Pacific Railway, Transcona, Manitoba
SEALEY, WILLIAM G., Mechanical Superintendent,
British Cordite Co., Nobel, Ont.

FOR CONSIDERATION AS JUNIOR

California

BERG, HENNING J., Engineering Department,
Standard Oil Co. of Cal., Corcoran
LILLA, HERBERT L., Machinist's Mate, United States Navy,
U. S. S. Huntington, c/o Postmaster, San Francisco

Connecticut

BARNETT, SYDNEY A., Engineering Draftsman,
Hugh L. Thompson, Consulting Engineer, Waterbury

Illinois

STUERMAN, ROBERT V., Superintendent Heating Department,
Springfield Gas & Elec. Co., Springfield

Kentucky

SEATON, EDWARD W., Engineering Department,
Ashland Iron & Mining Co., Ashland

Maryland

LEDNUM, JAMES M., Junior Engineer,
Davison Chemical Co., Curtis Bay
NELSON, ROBERT W., Foreman Shrapnel Shop,
Bartlett Hayward Co., Baltimore

Massachusetts

BAKER, CHARLES H., JR., Member of Firm,
Norton Co., Worcester
BARRY, EDWARD H., Sales Engineer,
The Elliott Co., Boston
CHURCHILL, F. LORING, Instructor in Mechanic Arts & Drafting,
High School, Quincy

Michigan

COTTRELL, HOLMES A., Carburetor Engineer,
Detroit Lubricator Co., Detroit
MOSES, CARL A., Insurance Engineering, Detroit

New Jersey

ILIFF, WILLIAM L., Sales Engineer,
Hyatt Roller Bearing Co., Newark
RAUSCH, ROSWELL H., Engineer,
Niles-Bement-Pond Co., Plainfield
ROSS, JOSEPH M., Mechanical Engineer,
Thomas A. Edison, Inc., Silver Lake

New York

BUSHNELL, BURDGE O., Mechanical Engineer,
New York Quebracho Extract Co., Brooklyn
DERRY, GARDNER C., Sales Engineer, Rochester
ENGESSER, BENJAMIN M., Apprentice Engineer,
Pierce-Arrow Motor Car Co., Buffalo
MINOTTY, JOSEPH P., Mechanical Draftsman,
Combustion Engineering Corp., New York
MURPHY, AMBROSE E.,
With Remington Typewriter Co., Ilion
OUTTERSON, CHARLES R., Sulphite Superintendent,
Carthage Sulphite Pulp & Paper Co., Carthage
WEBER, ROBERT L., Jr., Draftsman,
Combustion Engineering Corp., New York

Ohio

HODOUS, LOUIS W., Construction Supervisor,
The Canfield Oil Co., Cleveland
LANEY, THOMAS G., Jr., Student, Lima

Pennsylvania

CARVIN, FRANK D., Engineer of Tests,
Schaum & Uhlinger Co., Inc., Philadelphia
PARK, JOHN F., Jr., with
Dodge Sales & Eng. Co., Philadelphia
WORTH, PAUL, Mechanical Engineer,
Heine Safety Boiler Co., Phoenixville

Tennessee

LYLE, ALEXANDER B., Superintendent,
Stickney & Montague Co., Chattanooga

Texas

BLAKESLEE, WALTER A., Instructor in Mechanical Engineering,
Rice Institute, Houston

Washington

DONOVAN, PHILIP L., Purchasing Agent,
Bloedel Donovan Lumber Mills, Bellingham

APPLICATIONS FOR CHANGE OF GRADING

PROMOTION FROM ASSOCIATE MEMBER

New Jersey

KNIGHT, WILLIAM, Assistant Mechanical Engineer,
Crocker-Wheeler Co., Ampere

Pennsylvania

McGRAIL, FRANCIS J., Foundry Superintendent, Struthers-Wells Co., — Warren

Canada

STENBOL, CARL, Superintendent Steel Department, Canada Cement Co., — Montreal

PROMOTION FROM JUNIOR

Indiana

BARRETT, WALTER A., Mechanical Engineer, The Bass Foundry & Machine Co., — Fort Wayne

Massachusetts

CARROLL, M. B., Commercial Engineer, General Electric Co., — Lynn

New Jersey

ROYLE, VERNON E., Mechanical Engineer, John Royle & Sons, — Paterson

New York

HORTON, CHARLES M., Industrial Writer, — New York

Ohio

MANLEY, SUMNER M., Mechanical Engineer, The Proctor & Gamble Co., — Ivorydale

MAROT, EDWARD H., Sales Engineer, Hyatt Roller Bearing Co., — E. Cleveland

Tennessee

ALLEN, WHARTON H., Secretary-Treasurer, Allen-Scales Engineering Co., — Nashville

South America

NELSON, ERNEST B., Assistant Engineer, Andes Copper Mining Co., — Chanaral, Chile

Promotion from Associate-Member	3
Promotion from Junior	8
Total	127

NECROLOGY

ARTHUR BEARDSLEY

Arthur Beardsley was educated as a civil engineer at Rensselaer Polytechnic Institute, and was graduated in 1867 with the degree of Civil Engineer. Following his graduation, he was employed for one year as assistant engineer at the Hoosac Tunnel. In 1868, he entered private practice as a civil engineer and architect. In the following year, he was appointed instructor in civil engineering, physics and industrial mechanics at the University of Minnesota, and in 1870 was appointed to the chair of Civil Engineering and Industrial Mechanics at the University. In 1872, he was called to the chair of Mechanics and Engineering at Swarthmore College.

Mr. Beardsley was elected a life member of the Society in 1883, three years after its organization. He died on January 22, 1917.

J. ANSLEY HARTFORD

J. Ansley Hartford was born in Pittsburgh, Pa., on October 17, 1871. He received his early education in the public schools of Pittsburgh, and was graduated from the Pittsburgh Central High School at the age of 16. He served a four-years' apprenticeship as machinist at the Black Diamond Steel Works. He spent the next five years with the Westinghouse Electric and Manufacturing Co., entering as a machinist and being promoted through the tool-making division to the position of outside construction engineer, working on some of the largest power installations in the country.

In the meantime he had studied mechanical and electrical engineering at night, and was given charge of the electrical equipment of the Westinghouse Machine Company at East Pittsburgh. He remained at Pittsburgh eleven years in the capacity of factory engineer responsible for all service machinery. He designed the switchboard in use at the Pittsburgh plant. He represented the company in its joint betterment work with the Westinghouse Electric Co., organizing the Casino Technical Night School, Casino Restaurant and Library.

In 1910 he accepted the position of superintendent of design and manufacturing of the tractor works of the Smith Manufacturing Co., of Chicago. Later he designed the Breese motor plow and became secretary and general manager of the company organized to manufacture it. In February, 1916, he accepted the position of experimental and productive engineer with the Garford Motor Truck Co., which he held at the time of his death.

Mr. Hartford became an Associate of the Society in 1914. He died at Lima, Ohio, on March 17, 1917.

ALBERT C. STEBBINS

Albert C. Stebbins was born on September 19, 1845, in Monson, Mass., and received his education in the Monson Academy. When 19 years old, he came to New York City and worked for William Soules in the wool and flax business. Feeling the necessity of taking up a trade, he apprenticed himself as machinist with Lucius W. Pond, Worcester, Mass., from 1865 to 1870. In 1870 he went to New York as representative of Mr. Pond. Five years later, when the business changed hands and Mr. Pond's son, David W. Pond, took charge, Mr. Stebbins went back to Worcester as superintendent. In 1886, when the Pond Machine Tool Co. was established, Mr. Stebbins was made vice-president, and went to Plainfield, N. J., where he built the plant and had it running in the spring of 1888. In 1898, on the formation of the Niles-Bement-Pond Co., Mr. Stebbins was made vice-president and manager of the Pond works and continued in this capacity until the time of his death. He was also vice-president of the Pratt & Whitney Co., director of the Ridgway Machine Co. and vice-president of the Plainfield Savings Bank. He became a member of the Society in 1904. He died in Plainfield, N. J., February 28, 1917.

SILAS E. WEIR

Silas E. Weir was born on May 16, 1869, in Cookstown County, Tyrone, Ireland. He was educated at the Guilds Schools in London and served his apprenticeship with Coombe, Barboure and Coombe, Belfast, Ireland. Following this training, he went to British India to take charge of the installation and operation of a tea-drying plant located northwest of Calcutta. He had to give up this position, however, owing to illness, and he returned to Ireland for a period of about five years. He then came to the United States and worked for several firms—as general master mechanic with the Griffin Wheel Company, general superintendent with the Triumph Electric Company and works manager with the American Blower Company, retaining the last position until the time of his death. He became a member of the Society in 1914. He died in Detroit, on February 13, 1917.

WILLIAM C. WILLIAMSON

William C. Williamson was a member of the Society of long standing, having been elected to membership in 1882. He was a member of the firm of Williamson Bros. Company of Philadelphia. He died on February 12, 1916.

AMONG THE SECTIONS

THERE are several cities where the number of members of the Society is not as yet sufficient to warrant the establishment of a Section, but where a local organization exists which serves as a medium for bringing together the engineers of the locality. With the Section's reports will be listed in the future, therefore, reports of meetings of such organizations.

The Engineering Society of Nashville, Tenn., has opened its new headquarters at Room 109, Commercial Club Bldg., with secretary's office and technical reading room. The association holds a luncheon each Monday at 12.30 o'clock, with the exception of the first Monday of each month, when the meeting is held at 6.30 p. m., at which a set program is provided. Visiting engineers are always welcome at these events and at the association's quarters.

A Southwestern Society of Engineers has recently been formed at State College, New Mexico. This includes all branches of the profession. Until there are a greater number of engineers in any one branch than there are at present in a given locality, this organization will serve the purpose for which Sections in more thickly populated districts are established. The first convention was held on March 8, 9, and 10 and was a complete success. The papers presented would have done credit to the general meetings of some of the national societies.

ATLANTA

March 8. The Section was called to order for the election of officers for the ensuing year, and the following were elected: Oscar Elsas, chairman; Cecil P. Poole, secretary; Robert Gregg, J. N. C. Nesbit and Earl F. Scott.

Methods of interesting the members were discussed, and a trip was planned to the Atlantic Steel Co.'s plant. It was decided that such visits to industrial plants would be made periodically, and that at occasional meetings a paper prepared and read by one of the members would be the most effectual method of maintaining the interest of the members.

March 16. The Section visited the Atlantic Steel Company's works, and inspected with much interest the plant and equipment.

EARL F. SCOTT,
Section Chairman.

BIRMINGHAM

May 16. The Annual Meeting of the Birmingham Section will be addressed by Dr. Thornwell Haynes, President of Birmingham College.

April 11. This was one of the best meetings ever held by the Birmingham Section. It was addressed by Prof. M. Thomas Fullan, of Alabama Polytechnic Institute, on the subject of Technical Writing. Professor Fullan emphasized the fact that engineers should do more writing and the results would be profitable to both themselves and their readers. His clear and forceful description of the method of writing papers was much enjoyed and appreciated by his audience.

PAUL WRIGHT,
Section Secretary.

BOSTON

April 4 and 5. A two-day Joint Meeting of the Section and the American Institute of Electrical Engineers was held on these dates. The first session was held at the Engineers' Club on the evening of April 4. A buffet supper preceded the technical session, which was devoted to the general subject of Recent Developments in Steam Generation.

At this first session, Frederick Ewing presented a paper on Developments in Fuel Oil vs. Coal. This was followed by a paper on Up-to-Date Stoker Practice, by Sanford Riley, Mem. Am.Soc.M.E. High Pressures and Temperatures in a Modern Station was then discussed by I. E. Moultrop, Mem.Am.Soc.M.E. Prof. L. S. Marks, Mem.Am.Soc.M.E., reviewed the recent work of Messrs. Kreisinger, Ovitz and Augustine of the U. S. Bureau of Mines, on Combustion in Hand-Fired Boilers. The evening was closed by a paper entitled High Temperature Insulation of Boiler Settings, by P. A. Boeck.

The program for April 5 covered Isolated Plants and Central Stations, at the afternoon session, and Developments of Prime Movers, Condensers, Auxiliary Equipment, etc., at the evening session. Mr. Walter N. Polakov, Mem.Am.Soc.M.E., opened the afternoon session with a paper on Principal Factors in the Selection of Sources of Power. This was followed by a paper on Interesting Isolated Power Plants, by A. R. Meek, and by a second paper on An Isolated Power Plant in Connection with a Factory near Boston, read by William G. Starkweather, Mem. Am.Soc.M.E. Engineering Features and Results at the Holyoke Municipal Plant was presented by John J. Kirkpatrick, and W. F. Schaller closed the session with a paper on Coöperation between Isolated Plants and Central Stations, by Percival R. Moses and himself.

Following the afternoon session a dinner was served, at which brief addresses were made by several of the members and guests. Mr. Charles F. Weed, president of the Boston Chamber of Commerce, gave figures and statistics to show the almost incomprehensible amount of munitions being used in the war and compared this with the present quantity of munitions in this country. President Hollis outlined what the mechanical, electrical, civil and mining engineering societies are doing in assisting the Government to carry out its military and naval program. Prof. A. L. Williston, Mem.Am.Soc.M.E., and Dr. Frederick R. Hutton, Mem.Am.Soc.M.E., also spoke.

At the evening session, John A. Stevens, Mem.Am.Soc.M.E., gave a brief address upon the discussion of engineering subjects by engineering societies. R. A. Langworthy presented a paper on Engineering Features of Combined Heat and Power Distribution. Some remarks on turbine development in recent years were made by Dr. L. C. Loewenstein, Mem.Am.Soc.M.E., in the absence of Richard H. Rice, who was to read a paper on the Development of Steam Turbines. The meeting closed with a paper by Charles H. Bromley, entitled Recent Developments in Condensers and Modern High Vacuum.

WILLIAM G. STARKWEATHER,
Secretary.

BUFFALO

March 14. Before the Engineering Society of Buffalo, Karl W. Zimmerschied, of the General Motors Co., talked on the necessity of standardization as a measure of industrial preparedness, laying stress upon the standardization of detail. Mr. Zimmerschied said that efficiency is the great slogan of the times, but that it should be in evidence all along the line, as there is just as much efficiency in seeking facts which are of value and then utilizing them as there is in anything else. He also spoke of the adoption of the metric system, which he thinks is assured in machine-shop practice and engineering design, stating that the United States Government has recognized its value by adopting it in the aviation service.

April 4. Arthur S. Hurrell, superintendent of education in Indianapolis, Ind., spoke on Vocational Training, describing a survey prepared a short time ago which made clear the needs of industry and the wants of young men who proposed to enter mechanical occupations. He thought this would be of great value in the development of vocational education in other cities as well as Indianapolis.

Dr. George Smith, head of the Buffalo vocational-education department, and other educators commended the idea of the survey as a good thing for Buffalo and agreed that one of the needs in this city, if vocational training is to come into its greatest community influence, is public interest and support.

LOUIS J. FOLEY,
Assistant to Secretary.

CHICAGO

May 18. O. B. Zimmerman, Mem.Am.Soc.M.E., will present a paper on Small Internal Combustion Engines. The meeting will be held in the Hotel La Salle.

April 4. With an attendance of 125 at the regular dinner meeting, J. Philip Furbeck, of the Oxweld Railroad Service Co., gave a talk on Oxy-acetylene Welding. Mr. Furbeck limited his remarks to the practical application of oxy-acetylene welding in manufacturing, maintenance of equipment and machinery, reclamation work and the cutting of steel and wrought iron. A large number of lantern slides showed a great variety of work that had been done successfully at a cost considerably below that entailed by other methods.

This address was followed by a spirited discussion, joined in by a large number of those present. A nomination committee was selected, consisting of Messrs. C. C. Brooks, G. F. Gebhardt and Lewis M. Ellison, to present at the next meeting the names of candidates for the offices of the Section.

T. Wilson,
Corresponding Secretary.

MERIDEN

April 12. At the monthly meeting of the Meriden members E. P. Bullard, Mem.Am.Soc.M.E., president of the Bullard Machine Tool Company, gave a talk on the new Bullard employment plan which has been adopted by his company. Each person present at the meeting was given a pamphlet outlining the several branches of the plan, and Mr. Bullard then explained the workings in detail. He stated the workmen no longer asked for promotion or increased pay, as under the system this was taken care of automatically. A bonus is given if the men make full time all week, vouchers for this being paid after 30 days if the men are still in the company's employ, and a premium is paid for production above the standard amounts. The employees are insured without a medical examination. The workmen's welfare is looked after, and this is not confined to the shop, help being given in case of sickness in the home. Wages are higher under this system and the cost of production has been reduced, both workmen and company being benefited. Mr. Bullard said that while they were formerly much troubled with the constant loss of help, and the consequent necessity of breaking in new men, practically no such trouble exists under the new plan. In March only four men left the employ of the company out of something over 1,100 on the payroll. The company has an average of 1,500 applications for work per month and has closed its employment office.

C. K. Deckard,
Chairman.

MILWAUKEE

March 21. Capt. W. A. Moffat, U.S.N., commandant of the Navy Training Station at Great Lakes, Ill., addressed the Section.

Captain Moffat, who is an authority on naval matters, advocated the building of sea giants, volcanoes of power, by the United States, that would place the superdreadnoughts of foreign navies in the has-been class and would not necessitate the constant building of new ships. He considered it of little value to be continually building vessels which in a few years are out of date and go to the scrap-heap. The size of battleships, he said, should only be restricted by the limitations of the Panama Canal.

Capt. Moffat declared that a fleet of ships as large as it is possible to build would provide far greater protection and prestige to a nation than would a fleet of ships which are constantly being exceeded in size by those of other nations. He proposed ships of 60,000 tons displacement 250,000 hp., 995 ft. long and with a speed of 36 knots.

F. R. Dorner,
Section Secretary.

NEW ORLEANS

April 2. Preparedness was the subject of a paper by A. M. Lockett, Mem.Am.Soc.M.E., before the joint meeting of the Section and the New Orleans Association of Civil Engineers. The speaker told of the many and important ways in which the people of New Orleans may aid the nation in time of war, and his paper was discussed by Commodore V. S. Nelson, Major J. L. Schley, Major Richard C. Moore, Captain H. A. Drum, Lieut Moses, General Perrillat and Prof. Williamson.

Mr. Lockett said that the United States was now in the position of a contractor who had been awarded a large contract and must assemble men, material and equipment to carry it to completion. The engineers and chemists of the country have already aided in this work by making an industrial inventory of equipment. He pointed out that a contractor having both skilled and common labor at work on a job would not set a mechanic to do the work of the water boy nor the common laborer to do the work of a mechanic, neither should the Government use the engineers for other work than that for which they are especially fitted, but should place each man where his knowledge would be most valuable.

In discussing the paper, Commodore Nelson spoke of the need of the Navy for more men, and explained what enlistment in the Navy and Naval Reserve entails and the different grades of service. He also pointed out the need of men on shore, such as radio operators, electricians, mechanics for machinery and ship-repair men for operating mine layers and mine sweepers, and the great need of men in the flying corps.

Major Schley said that the engineers were especially suited for the work of "apostles of preparedness," as they took a matter-of-fact view of things and knew something of the number of men and quantities of material required to accomplish large undertakings.

Major Moore, of the U. S. A. Engineer Corps, spoke of the need of both material and men. Satisfactory arrangements for the first have been made, but there is need of many men both in the ranks and as officers. Captain Drum, of General Pershing's staff, who has recently come here to create interest in the army training camp, described the object of training camps and the advisability of universal military training and service, as this would give us an army of men "whose interest is for peace, whose hopes are for peace and who will vote for peace with honor." He urged the citizens of Louisiana to attend the camp to be opened at Alexandria, and carefully explained the requirements for such attendance.

Lieutenant Moses, U. S. N., gave specific advice as to how the organizations in New Orleans could join in the work of aiding the Government, and suggested that the Association of Commerce establish and maintain a perpetual stock-card system showing material actually on hand and ready for immediate delivery to the Navy Yard, and that the merchants coöperate to develop a transportation system to insure this delivery. Suggestions were also made as to the facilities for motor-boat repair at the mouth of the river and the building of submarine chasers as well as plans for medical attention at that point.

General Perrillat pointed out that the country now has in hand a gigantic work, and cited Great Britain's mistake in taking men from the munitions factories for the front and then having to recall them. He considered it advisable to have a census of men made and their abilities listed. Professor Williamson followed with the same thought as to the census.

In conclusion, the President of the Louisiana Engineering Society was asked to appoint a committee to take up the work of making the roster of the members of the Society.

H. L. Hutson,
Section Secretary.

NEW YORK

May 8. Siegfried Rosenzweig, Mem.Am.Soc.M.E., will speak on The Development of the Poppet-Valve Steam Engine With Special Reference to Its Present Status in the United States.

April 10. The following Committee was elected to nominate officers for the coming year: George S. Humphrey, chairman, Philander Betts, F. R. Low, W. W. Macon and Edward Van Wrinkle.

Secretary Rice described in detail his trip to the various Sections which had taken him as far west as Oklahoma City. He also outlined the work which engineers are doing in the present crisis, and told the members present how best to offer their services to the Government.

The paper of the evening was presented by Earle Buckingham, Mem.Am.Soc.M.E., and was entitled Standards of Business Success. Mr. Buckingham said that we are living in an age of combinations

[illegible] and it has been rather generally assumed and accepted that there was no limit to the profitable increase of a large concern. He then presented accessible figures to show what happens to several departments of a concern when it very largely increases the amount of business transacted. For the purchasing department he showed that, in every line of business he had examined, the cost of materials showed an increase disproportionate to the growth of the business. He said that, from experience, a growing firm's sales costs would increase faster than the gross amount of business increase. In like manner there can be no question that the cost of credits will increase faster than the costs of the business. Cost of production involved labor and overhead charges and the complete showing of the production end of American business could not be ascertained at present.

A. D. Blake,
Section Secretary.

MINNESOTA

[illegible] A banquet and entertainment was tendered Dr. Ira N. Hollis, President Am.Soc.M.E., at the Hotel Dyckman in Minneapolis. The guests present were addressed by Dr. Hollis, Dr. G. E. Vincent, President of the University, and Dr. Marion L. Burton, President-elect of the University. Dancing and a general get-together followed.

March 10. A symposium on steam locomotives was held at the Main Engineering Building of the University of Minnesota. Seven papers were read and many of them discussed, and an address was made by Dr. Hollis.

J. V. Martenis, Mem.Am.Soc.M.E., gave the opening paper, on Historical Development of the Locomotive. Locomotive Improvements, by Max Toltz, Mem.Am.Soc.M.E., was read by C. F. Shoop, Mem.Am.Soc.M.E. This was followed by Modern Methods of Locomotive Operation, by T. A. Foque, Mem.Am.Soc.M.E., and Historical Development of the Superheater on the Locomotive, by Geo. L. Bourne, Mem.Am.Soc.M.E., read by R. M. Ostermann, Mem.Am.Soc.M.E. A paper on the Use of Pulverized Fuel for Locomotives was read by J. E. Muhlfeld, Mem.Am.Soc.M.E., and papers on Economy of the Locomotive Superheater by R. M. Ostermann, and Feed Water Heating by George M. Basford, Mem.Am.Soc.M.E.

D. M. Forfar,
Section Secretary.

PHILADELPHIA

May 22. A joint meeting with the Engineers' Club and Affiliated Societies at Drexel Institute will be addressed by Willard Behan on Engineering of Men.

March 27. A joint meeting of this Section and the Philadelphia Chapter of the American Society of Heating and Ventilating Engineers was addressed by Walter J. Kline, of the American District Steam Heating Co., on District Heating.

Mr. Kline gave much thought to the design and financing of various systems, emphasizing the desirability both from the producers' and consumers' standpoint of the installation and use of meters.

March 30. The Engineers' Club of Philadelphia celebrated its fortieth anniversary by a banquet at the Bellevue Stratford Hotel. Patriotism and loyalty were the keynotes of the evening, and much was said of the part played by the engineer in construction and destruction in time of war.

References to salient points in the history of the Club were made. The Club was organized in December, 1877, with nineteen members, at whose residences the meetings were held for the first few months, after which the Club opened its own headquarters. After several changes it took possession of its present quarters at 1317 Spruce Street in 1907. Among receptions tendered by the Club to visiting engineers and engineering societies were one to Count Ferdinand de Lesseps in 1880, and one to the delegates from the Society of Engineers of France to the Chicago World's Fair in August 1893.

Following proceedings inaugurated in 1913, affiliation was effected in 1915 between the Club and the Philadelphia Sections of the American Institute of Electrical Engineers, The American Society of Mechanical Engineers, American Society of Civil Engineers, Illuminating Engineers, Technology Club of Philadelphia, Massachusetts Institute of Technology, Society of Automobile Engineers and American Society of Heating and Ventilating Engineers.

By a whirlwind campaign in the latter part of 1915, the club membership was increased within a few days from 524 to 2336, an increase of nearly 350 per cent.

W. R. Jones,
Section Secretary.

PROVIDENCE

May 21. Subject: Time and Motion Study.

February 28. An open meeting to which ladies were invited was addressed by M. R. Hutchison, Mem.Am.Soc.M.E., engineering advisor to Thomas A. Edison and a member of the Naval Consulting Board, on Edison, His Life and Achievements. Mr. Hutchison illustrated his lecture with lantern slides and moving pictures of interest.

March 28. The Providence Engineering Society held a very largely attended meeting, at which Dr. Ira N. Hollis, President Am.Soc.M.E., George H. Pegram, President Am.Soc.C.E., and Harold W. Buck, President Am.Inst.E.E., spoke on The Engineer and Organization.

Dr. Hollis pointed out the relations between the engineer and democracy, dwelling on the fact that the spread of democracy seems to have run parallel with the growth in engineering achievements from the time of James Watt, inventor of the steam engine, down to the present. The speaker said that it was the duty of engineers to stand for the principles of democracy and use their influence to have trained men picked for high offices in the government; and in order to do this the coöperation of engineers throughout the land is necessary.

Mr. Buck dwelt on the fact that all engineering problems are coöperative, and asked for coöperation between the engineer and the scientist, instancing Faraday's work which a century ago was looked upon by engineers as fanciful and pretty but which today forms the basis of great electrical attainments.

Mr. Pegram suggested that if our Government had a department of public works there might be improvement in the handling of many problems. The Government has but recently officially recognized the engineer, but without his services it is doubtful how much progress could be made.

Following these addresses General Abbot, of the Rhode Island National Guard, spoke on coöperative work among the engineers necessary in time of war. Dr. Faunce, of Brown University, also emphasized the necessity for coöperation, and Major Buxton, of the National Guard, advocated compulsory military training.

A. E. Thornley,
Corresponding Secretary.

ST. LOUIS

The St. Louis Section sends in a description of the organization and work of the Engineers' Club of St. Louis, which, in its reincorporated form, includes the Club and the Local Sections of the National Societies of Civil, Mechanical and Electrical Engineers and of the American Society of Electrical Contractors. The description was given in a recent paper by Mr. F. G. Jonah, presented before the third conference on Engineering Coöperation.

The Club maintains permanent quarters, containing the office of a secretary, who devotes his whole time to Club affairs, a fairly good reference library, a reading room supplied with all the technical journals, and an auditorium equipped with a motion-picture machine.

Meetings are held weekly during the season and papers for presentation are arranged for by the various Sections in turn. The Club publishes a bi-monthly journal in which papers and discussions are printed, and issues a bulletin monthly, devoted to general news.

The Club has attempted in a dignified manner to influence the solution of public questions involving engineering and scientific consideration and maintains, among others, the following standing committees: Civic, City Plan, City Building Code, Quantity Surveying, and Good Roads. These committees watch legislation in city and state, and are frequently requested to coöperate with the municipal authorities.

STUDENT BRANCHES

Members of Student Branches are requested to notify the Secretary of any change in address as promptly as possible, in order to facilitate delivery of The Journal.

THE University of Cincinnati Student Branch extends an invitation to the Student Sections in the vicinity of Cincinnati to visit that city at the time of the Spring Meeting of the Society during the week of May 21. This, the Semi-Annual Meeting of the Society, offers to Student Members the opportunity to become better acquainted with the manner of conducting the work of the Society. Students are invited to attend the professional sessions and hear the discussions of engineering problems of the day.

One of the important features of the Spring Meeting will be the visits to industrial plants, of which there are a number in Cincinnati. Invitations will be extended to Student Members to accompany the parties on the various trips of inspection arranged to these plants, and also to the places of interest scheduled on the program, and in all probability students will be invited to attend the social affairs.

Plans are well under way for a big Joint Meeting of the Student Branches to be held at the University of Cincinnati. It is hoped that a goodly number will go to Cincinnati, and that this Joint Meeting of Student Sections will be a record breaker. This meeting will afford an excellent opportunity for the men from the colleges to become acquainted. The University of Cincinnati men are looking forward to this Joint Meeting with a great deal of anticipation.

On April 13, a convention of Student Members was held at the Engineering Societies' Building, New York, and delegates of the following branches participated: Columbia University, Lehigh University, New York University, Polytechnic Institute of Brooklyn, Rensselaer Polytechnic Institute, Stevens Institute of Technology and Syracuse University.

The meeting was divided into two sessions, the first of which was addressed by Prof. Lionel S. Marks, Mem.Am.Soc.M.E., on The Explosion Process in Gas Engines, by Prof. Arthur M. Greene, Jr., Mem.Am.Soc.M.E., on Pumping Engines, and Prof. Charles E. Lucke, Mem.Am.Soc.M.E., on Surface Combustion. Prof. F. R. Hutton, Mem.Am.Soc.M.E., opened the meeting with an introductory address in which he outlined the rapid development of the Student Branches of the Society, and spoke of the great benefit derived from joint meetings of branches.

Following the professional session, those present were shown through the Engineering Societies' Building, after which supper was served. In the evening a Smoker was held, at which Mr. "Jack" Armour, of *Power*, entertained and made a decided hit. All present joined in patriotic and college songs and Prof. William Kent, Mem.Am.Soc.M.E., spoke on the opening days of the war and compared them with the days of '61. A collation closed the meeting.

The Committee on Student Branches consists of Frederick R. Hutton, chairman, George M. Brill, William Kent and George A. Orrok; and John L. Kretzmer and James G. Manning, of Columbia, George H. Hauser, Jr., and Joseph Gilman, of N. Y. U., Arthur A. Bielek, chairman, and Frank R. Stamer of Poly, and Sprague Hazard and Alvin G. Searles of Stevens formed the committee on arrangements for the joint meeting.

ARMOUR INSTITUTE OF TECHNOLOGY

March 14. Mr. S. W. Thal gave an elaborate illustrated lecture on Automobile Ignition, followed by G. M. [illegible] talk on Walter Tractors.

March 28. After the regular business Mr. [illegible] talk on Thermit Welding. R. E. Marks spoke on Motion Pictures and G. M. Fritze discussed Trackless Trains thoroughly [illegible] interesting manner.

April 1. G. W. Jewell, of the Builders Iron Foundry, [illegible] illustrated lecture on the Venturi Meter, Its History, [illegible] and Uses. The lecture was followed by discussion.

Abe J. [illegible]
Branch Secretary

BUCKNELL UNIVERSITY

April 9. This was the first meeting of the Spring Term. C. D. Maurer, '17, gave an instructive talk on Power Plants, in which he described the equipment of the Shamokin Power Plant.

He was followed by Prof. F. E. Burpee, Mem.Am.Soc.M.E., who spoke on the Engineer Officers' Reserve Corps, and announced that he had offered the services of himself and the graduating class to the War Department.

C. M. Kriner,
Branch Secretary

CASE SCHOOL OF APPLIED SCIENCE

April 10. Advertising was the subject of an address by C. H. Henderson, of the Cleveland Twist Drill Co. The talk was full of snap, and contained much advice for the young engineer in business.

Alexander Trenhoft,
Branch Secretary

UNIVERSITY OF CALIFORNIA

March 24. The banquet held jointly with the Student Branch at Leland Stanford University was a great success. After many interesting addresses and excellent music, a number of the members of this Branch attended a theatre party.

April 3. William A. Doble, Mem.Am.Soc.M.E., read an interesting paper on the new Doble steam engine for automobiles, pointing out the principles upon which it is based. It was of timely interest and was much appreciated.

John H. Fenton,
Branch Secretary

CARNEGIE INSTITUTE OF TECHNOLOGY

March 21. W. O. Renkine, who is connected with A. M. Byers Co., addressed the Branch on the subject of powdered coal.

Mr. Renkine said that although powdered coal as a fuel had been experimented with as far back as a hundred years ago, the first practical application of it was not made until 1894 and was monopolized by the cement industry. Due to the high cost of oil and scarcity of natural gas it was found necessary, about two years ago, to experiment with powdered coal in the production of iron and steel.

In his talk Mr. Renkine described the various stages of pulverizing, storing and burning powdered coal, and the obstacles met with during the experimental development of the processes.

James H. Davis,
Branch Secretary

UNIVERSITY OF CINCINNATI

March 23. An interesting talk was given by Calvin W. Rice, Secretary Am.Soc.M.E., on the work that engineering societies are doing for the nation in regard to national defense. He described the formation of the Naval Advisory Board, the Munitions Standardization Committee and the Committee on Industrial Preparedness. He advised all students to participate in all student activities and to strive for responsible positions on committees that serve the business world. He also urged the students to make use of the free service of the Engineering Societies' Library.

[illegible] A. M[illegible], Mem.Am.Soc.M.E., depicted part of a [illegible] concern in the [illegible] explaining systems for numbering parts and [illegible] work throughout [illegible]. This was followed by [illegible] and employment problems. [illegible] devoted to the design of new [illegible] buildings. Location, light, sanitation and pleasant surroundings were mentioned as requisites for a satisfied working force.

Henry A. Wo[illegible],
Branch Secretary.

COLORADO AGRICULTURAL COLLEGE

[illegible] 3. A lengthy discussion regarding the process of manufacture of ball bearings was given by Prof. L. D. Crain, Mem.Am. Soc.M.E. The talk was well illustrated with slides from the S. K. F. Ball Bearing Co., and chief topics of the discussion were the various operations of manufacture, kinds of material used and the extensive application of ball bearings.

E. C. Johnson,
Branch Secretary.

UNIVERSITY OF COLORADO

April 10. At the regular meeting of the Branch, Prof. J. A. Hunter, Mem.Am.Soc.M.E., reported on the convention of the oil men called by the U. S. Bureau of Standards, at Washington, D. C., for the purpose of establishing standards by which gasoline and oils might be more uniformly classified. His report was supplemented by a description of the oil-testing equipment used in the Bureau, and a discussion followed.

W. S. Beattie,
Branch Secretary.

COLUMBIA UNIVERSITY

February 28. The United Engineering Societies of Columbia University were addressed by Charles Ferguson, who had accompanied Colonel House on a trip through Europe, and who, on his return, presented a report on industrial conditions there to President Wilson.

Mr. Ferguson said that he considered the engineer to be the dominant factor in the future regulation of society, and emphasized the importance of the engineers' viewpoint on vital matters. He said that those who conquered in the struggle of business competition would be better fitted to control the workings of the state than any other group of men, and the engineer is the man to develop the great business system to its fullest measure.

John L. Kretzmer,
Branch Chairman.

CORNELL UNIVERSITY

March 26. What is a Ship was the subject of an address by Prof. G. R. McDermott, naval architect and head of the ship-design department of Sibley College.

Professor McDermott pointed out that the developments of the modern day have made it necessary to include in the name *ship* airships and submarines. He explained the advantages of each of the different classes of ships. He described the problems of building and launching, and called attention to the fact that every branch of engineering is made use of in the construction of all vessels.

S. M. Barr,
Branch Secretary.

STATE UNIVERSITY OF IOWA

March 29. F. M. Kolar gave a talk on High Speed Steel, dealing with the annealing, hardening and tempering of it.

C. L. Severin,
Branch Secretary.

UNIVERSITY OF KANSAS

April 3. The Ninth Annual Meeting of the Branch was held in three sessions, with Dean P. F. Walker, Mem.Am.Soc.M.E., H. A. Fitch, W. C. Baxter, Mem.Am.Soc.M.E., Calvin W. Rice, Secretary Am.Soc.M.E., A. Hurlburt, Mem.Am.Soc.M.E., R. A. Rutledge and W. W. Walford as the speakers.

As a departure from the usual program, three illustrated lectures were given by S. K. F. Co., on the Present-Day Application of Ball Bearings; by the Lodge and Shipley Machine Tool Company, on the Manufacture and Testing of Lathes, and by the National Tube Co., entitled From Ore to Finished National Pipe, respectively. Dean Walker made the opening remarks, and Mr. Fitch spoke on Industrial Development in the Southwest. Mr. Baxter, who is connected with the Wichita Pipe Line Co., discussed Natural Gas Engineering, and he was followed by Mr. Rice, who spoke on the Engineer in Public Service. Mr. Hurlburt's topic was Engineering in Public Utilities.

At the afternoon session and the banquet in the evening Mr. Rutledge, Chief Engineer of the Santa Fé Railroad, gave an address on Qualifications for an Engineer, and Mr. Walford, head of the advertising department of this road, addressed the Branch on A Tour Through the Southwest.

April 12. Mr. L. H. Chase, head of the farm-machinery department, gave a very interesting talk on Agricultural Engineering and Its Importance.

Harlan A. Russell,
Branch Secretary.

STATE UNIVERSITY OF KENTUCKY

March 17. The Branch was most fortunate in securing Samuel Rea, President of the Pennsylvania Railroad, to speak at its meeting.

Mr. Rea related in an informal way some of the tremendous problems involved in operating the great system of which he is head, discussing these problems from both financial and engineering standpoints. He referred to the expansion of the system, telling how it was found necessary to build the two tunnels under the Hudson River between New York and New Jersey in order to meet the conditions of growing traffic.

By way of advice to the students present, he said that the man without a technical education cannot hope to compete in the field of engineering or other professions requiring technical knowledge with one having the advantages of such a training. He considered conditions in the profession were now more exacting than when he entered it, and stated that although he himself had been charged with supervisory responsibility for more than nine years he would not undertake the engineering details of some of the works which the Pennsylvania Railroad had undertaken in its tunnel construction.

April 8 to 15. Prof. F. Paul Anderson, Mem.Am.Soc.M.E., and Prof. W. E. Freeman, conducted the senior class on an inspection trip to Chicago and vicinity. The party paid visits every day to various industrial plants and points of interest.

D. S. Springer,
Branch Secretary.

LEHIGH UNIVERSITY

March 22. W. P. Berg, '17, and H. E. Kantner, '17, were the speakers. Mr. Berg gave a talk on the Manufacture of Paper from Wood Pulp, describing how the paper is prepared from chemically treated wood pulp, obtained from the wood either by the soda or bisulphate process, and so on through the various stages to the finished product. Mr. Kantner spoke on Present-Day Applications of Ball Bearings, bringing out the points in their manufacture, design and uses by means of a large number of lantern slides.

F. M. Porter,
Branch Secretary.

LELAND STANFORD JR. UNIVERSITY

March 24. The Branch joined with the University of California Branch in a banquet at the Engineers' Club of San Francisco. Dr. W. F. Durand, Mem.Am.Soc.M.E., acted as toastmaster, introducing as speakers W. K. Potts, C. E. Grunsky, Prof. H. B. Langille, Mem.Am.Soc.M.E. and G. W. Dickie, Mem.Am.Soc.M.E. The evening was greatly enjoyed by those present, and it is hoped to make this an annual event of the two Branches.

The form of program was somewhat original, showing a curve

on which the readings indicated the periods during the evening at which the various entertainment features would take place.

A. L. Morgan,
Branch Secretary.

LOUISIANA STATE UNIVERSITY

March 14. E. C. Freeland read a paper on Burning Bagasse, in which he compared the fiber content of the cane at various stages of the process of sugar manufacture. He illustrated the processes of burning bagasse.

J. A. Nadler,
Branch Secretary.

RENSSELAER POLYTECHNIC INSTITUTE

March 5. Dr. Ira N. Hollis, President Am.Soc.M.E., spoke on The Engineer and the National Crisis. Dr. Hollis, referring to the adage that "history repeats itself," gave illustrations in the present events; he also described what he considered efficiency and the attitude of the people toward the government, impressing upon the minds of those present that it was the duty of the engineer to increase the efficiency of the government.

H. M. Hammond,
Branch Secretary.

SYRACUSE UNIVERSITY

It has been the practice of the Student Branch to have as many good talks as possible given by men experienced in the engineering field at their meetings held every other week, and a debate between the mechanical and electrical Student Branches was a feature of the year.

R. M. Milford,
Branch Secretary.

UNIVERSITY OF MAINE

March 21. N. A. Robbins, Mem.Am.Soc.M.E., chief engineer of the Orono Pulp and Paper Co., outlined the growth of the power plant of this company and described the problems which have come up for solution in connection with it from time to time. The plant is a modern one in every way and furnishes a good example of an up-to-date power plant in a present-day manufacturing establishment.

R. E. Fraser,
Branch Secretary.

MASSACHUSETTS INSTITUTE OF TECHNOLOGY

March 23. John A. Stevens, Mem.Am.Soc.M.E., was the speaker at the smoker held by the Branch on this date. Mr. Stevens spoke of the value of the man to the company employing him and related many of his sea experiences while chief engineer of the S.S. St. Paul. K. C. Richmond, '16, spoke on Rock Tunnel Construction, describing the machinery used and stages in the work.

March 30. Patent Law was the subject of an address by a member of the class of '88, Odin Roberts, Mem.Am.Soc.M.E., a prominent patent attorney. Mr. Roberts gave examples illustrating the salient points of our patent law as it stands today.

E. P. Warner, '17, followed with a talk on The Stresses Developed in Aerial Propellers, illustrating his talk with plots and diagrams and a full-sized propeller to show sections and angles.

May 6. J. A. Moyer, Mem.Am.Soc.M.E., spoke on Steam and Gas Tnrbines, illustrating his talk with lantern slides. The speaker answered many questions about both types of turbines, materials used, efficiencies, etc. H. M. Brayton, '17, spoke on Engineering Charts.

Edward W. Rounds,
Branch Secretary.

NEW YORK UNIVERSITY

It was decided to replace the April meeting by the courses given especially for mechanical engineers at the Brooklyn Navy Yard. Passes were obtained for each member, and instruction was given on board the U.S.S. New Jersey under the supervision of a lieutenant detailed on this ship. Three courses were being given, Ordnance and Gunnery, Electrical and Steam Engineering, and Signaling and Navigation, but with the declaration of war these were discontinued. However, a course of signaling is being established at the University under the supervision of Prof. C. P. Bliss, and it is expected that most of the members will attend.

Joseph Gilman,
Branch Secretary.

OHIO STATE UNIVERSITY

March 21. Prof. John R. Allen, Mem.Am.Soc.M.E., gave an interesting lecture on Engineering in Turkey, in which he described the manner in which construction work is done there and the difficulties encountered. He urged the engineers to become proficient in foreign languages, as it is impossible to do an export business in one language. He stated that the American exporter through his shortsightedness, loses his greatest opportunity in the line of raw materials, by having to sell his goods through European salesmen who are able to speak the required language.

F. E. Smyser,
Branch Secretary.

OREGON STATE AGRICULTURAL COLLEGE

Mrch 15. Mr. Graf described the interesting things seen by him on his trip East. Mr. Goldman read a paper on The Engineer in Practice, in which he called attention to the opportunities open to the engineer.

April 5. After the transaction of the regular business, Mr. Peaslee gave an informal talk on the Engineer Officers' Reserve Corps and the Opportunity in It for Engineers, and Mr. Orr gave an informal talk on Plant Operation.

Arthur O. Leech,
Branch Secretary.

UNIVERSITY OF PITTSBURGH

April 12. Mr. Goldberg read a paper on the Uniflow Engine, treating of its economy, problems of design and development. The paper was discussed by Messrs. Noss and Lynch. At this meeting plans were talked over regarding the part to be taken by engineers in the Preparedness movement.

March 15. Mr. Hutcheson read a paper on Superheaters, which dealt with the progress and history of superheated steam. The paper was discussed by Mr. Wachter and Mr. Russo.

F. C. Noss,
Branch Secretary.

PURDUE UNIVERSITY

March 15. Mr. Hannun, of the mechanical department, spoke on the uniflow steam engine. His discussion dealt primarily with the type of uniflow engine manufactured by the Skinner Engine Co., with which he was formerly connected, and with the Stumpf engine.

March 27. Prof. L. W. Wallace, Mem.Am.Soc.M.E., talked along the lines of locomotive engineering, devoting special attention to the advantages of the superheater engine over that using saturated steam. The talk was based upon data derived from tests in the Purdue Locomotive Laboratory and that of the Pennsylvania Railroad, and was illustrated with many photographs.

W. G. Schutt,
Branch Secretary.

THROOP COLLEGE

March 5. A most successful joint meeting of the mechanical and electrical Student Branches was held, with Earl Ovington as the speaker.

Mr. Ovington, who is a pioneer in aviation, being the first man to fly a monoplane in the United States and the winner of several big races in exhibition flying, held the attention of his audience with descriptions of his wide experiences which he illustrated with lantern slides.

Reginald Coles,
Branch Secretary.

VIRGINIA POLYTECHNIC INSTITUTE

April [illegible]. The King of the Rails was the subject of a motion picture of much interest. The film was furnished through the courtesy of the General Electric Co.

April 19. G. F. Minor gave an interesting lecture on the Pelton Water Wheel, which was illustrated with slides supplied by The Pelton Water Wheel Co.

G. F. MINOR,
Branch Secretary.

UNIVERSITY OF WASHINGTON

March 9. The Branch held a meeting in Engineering Hall, when the object of the organization was outlined and plans for future meetings and trips were formulated. The following officers were elected: Chairman, Philip G. Johnson; Secretary, Claire L. Egtvedt, and Treasurer, Thomas P. Evans.

March 22. The accurate determination of secondary stresses in complicated steel castings, particularly truck frames and body bolsters of freight cars, was the subject of the lecture before the Branch by George B. Floyd, of the American Steel Foundry Co., of Chicago.

Mr. Floyd recited the advantages of the Berry extensometer in the determination of the weak parts in castings, and described in detail, with the aid of blue prints, the results of extensive experiments conducted by his company with this apparatus.

WALTER HENRY KURTZ,
Branch Secretary.

UNIVERSITY OF WISCONSIN

March 15. At the regular semi-monthly meeting of the Branch, A. G. Hoppe presented a paper on Advertising, in which he dealt with fake advertisements of an engineering nature found in non-technical journals, using an example from a current magazine.

March 26. The first annual banquet was held, with Calvin W. Rice, Secretary Am.Soc.M.E., as the guest of honor; Prof. G. L. Larson, Mem.Am.Soc.M.E., as toastmaster, Dean F. E. Turneaure and Prof. J. G. Callan as speakers.

As his message to the Branch, Dean Turneaure emphasized the value of Outside Activities for the Student and the Engineer. Mr. Rice urged the technical student to consider how he could best serve his country in the present crisis, suggesting that the trained man should not rush into private enlistment but hold himself in readiness to be placed where he can do the greatest amount of good. Professor Callan spoke upon the Broader Engineering Education, and commended the present tendency of engineering schools to broaden their training by the addition of cultural courses. A. E. Kelty, president of the Branch, gave the response.

March 29. Mr. Grant described the various methods he had tried in analyzing the vibration of an automobile engine. Magazine reviews were given by J. M. Wood, on the manufacture of steel balls; Mr. Roberts on the characteristics of the 1917 automobile, and Mr. Seelbach on the conference of motor-boat manufacturers with Secretary Daniels regarding small speed power boats for the Navy.

JOHN M. WOOD,
Branch Secretary.

EMPLOYMENT BULLETIN

THE SECRETARY considers it a special obligation and pleasant duty to make the office of the Society the medium for assisting members to secure positions, by putting them in touch with special opportunities for which their training and experience qualify them, and for helping anyone desiring engineering services. The Society acts only as a clearing house in these matters.

POSITIONS AVAILABLE

In forwarding applications, stamps should be enclosed for transmittal to advertisers; applications from non-members should be accompanied by a letter of reference or introduction from a member, such reference letter to be filed with the Society. Copy for notices must be in hand by the 15th of the month.

ESTIMATOR. Plant in Western New York manufacturing steel-plate tanks and receptacles, desires the services of estimator. In first letter state age, experience, training, single or married, salary, present employment. 634.

HEATING AND VENTILATING ENGINEER, young technical graduate, three or four years' experience. Location Ohio. 665.

SUPERINTENDENT for automobile-tire factory, man who understands compounding, and knows machinery and installation. Location Minnesota. 666.

PLANNING DEPARTMENT AND TIME-STUDY MEN. Well-established firm offers exceptional opportunities for effective and interesting work to engineering graduates with substantial experience with modern industrial accounting with special reference to time study, determination of standard tasks and planning and scheduling production. State age, education, experience, present and expected salary. 679.

DRAFTSMEN, experienced, preferably not over 30. Permanent employment and advancement to capable men. 751.

POWER ENGINEER for large industrial corporation operating own steam and electrical power plants. Young man with executive ability, mechanical or electrical-engineering graduate, experienced in power plant and power distribution, design, and operation. State age, school, year of graduation, detailed experience, salary expected. Location Michigan. 763.

PRODUCTION MANAGER, 30 to 40, married preferred, clean-cut, aggressive, of generous build. Technical graduate preferred. Must have had practical experience in every branch, such as shop work, drawing-room work, tool designing; must also have had successful experience of at least five years; must be thoroughly informed in modern cost and planning-department methods. Electrical manufacturing experience preferred, though not absolutely essential. Location vicinity of New York. Salary $3,000 to $4,000. 890.

ENGINEER for clock company in New England. Experience in handling men, up to 500, engaged in manufacture of woodworking parts from raw timber through to highly finished exterior, and supervising of numerous small parts in clocks. Must be capable of improving quality and increase output. 917.

THREE DRAFTSMEN, pipe work; steam, hydraulic, water, and air piping. Also MACHINE DESIGNERS and plant layout men. Also first-class STRUCTURAL STEEL and POWER-PLANT man. Location Ohio. 927.

DRAFTSMAN familiar with valve detail and design and experienced in estimating and layout work. Excellent opportunity for competent man. State age, experience in detail, references and salary expected. Location New York State. 928.

RECENT TECHNICAL GRADUATES for shop positions with company manufacturing recording meters, with opportunity to advance in other lines of work as business expands. Location Boston. 933.

YOUNG TECHNICAL GRADUATE with one or two years' experience in steam engineering, for testing work. Location New Jersey. State age, experience and salary expected. 939.

INSPECTOR, experienced in expediting machinery deliveries. Giving particulars, experience, etc. 942.

DRAFTSMAN on design of new machinery, equipment, general work in connection with plants of a steel and wire company. 945. American Steel & Wire Co., Mr. P. Morrison, Ch. Draftsman, Trenton, N. J. Telephone 3225.

THREE HIGH-GRADE ENGINEERS, thoroughly conversant with application of all phases of production and cost work, able to carry through alone handling of contracts. Essential qualifications, pro-

nounced power of observation and analysis, ability to plan and organize, practical type of mind, tact and sound judgment in dealing with clients. Headquarters New York. 946.

FACTORY ENGINEER, technical graduate, with successful record as assistant superintendent or superintendent for concern manufacturing polishing and bufing wheels, and employing 150. Must be conversant with scientific management and able to secure, retain and handle successfully both men and women. Give age, experience, education, and salary expected. Permanent position with splendid future for right party. 948.

DRAFTSMAN experienced in factory design and installation of elevator and conveying machinery in general cement-plant work. Location Pennsylvania. 949.

RECENT ENGINEERING GRADUATE to take up economy studies in pole-line and cable-plant construction. Man having some experience in estimating cost of such construction given preference. State experience and salary desired. New York. 952.

MAN to run COST OFFICE. One with practical machine-shop experience, and who understands theory of cost accounting, and has had experience in instructing clerks. Employ about 475 in diversified work with foundry, pattern and machine shop. Salary $25 a week. Location Massachusetts. 953.

ENGINEER. Young technical graduate to engineer, design and take charge of production of electro-mechanical devices, and to conduct performance tests on standard and special designs. Salary to start $100. Location Middle-West. 954.

CHIEF ENGINEER for industrial power plant operating 10,000 boiler hp. and 5,000 electrical. Must be well up on combustion and plant maintenance. State salary. Location North Carolina. 956.

ENGINEER on design and experimental work. Good personality. Salary to start $1200. Location Elizabeth, N. J. 957.

COMPANY with factory in western Maryland desires man with technical training, in the capacity of assistant designer and works manager. To assist in designing special machinery and developing ideas; analyze machine operations, prescribe equipment and devise means to effect speedy and economical production; superintend manufacturing such machinery. Requires ability of thoroughly practical master mechanic with original ideas as to methods, knowledge of modern shop practice, familiarity with design and application of time-saving fixtures, executive ability and diplomacy necessary to successfully direct manufacturing plant. No question of salary if right man applies. In first letter state full particulars and experience from technical degree which will be held confidential. 958.

SALESMAN, steam power-plant specialties. College graduate preferred, and, if possible, having experience in similar line of work in Philadelphia. Should be capable of taking charge of office eventually. 959.

DRAFTSMEN (three or four) experienced in plant layouts and special-machinery design. 963.

PRODUCTION ENGINEER to take charge of cost-reduction work in Canadian shop manufacturing air compressors, rock drills. State age, experience and salary expected. 974.

INDUSTRIAL PLANT ENGINEER. Mechanical engineer, preferably college graduate, with several years' all-round experience which would fit him to take charge of design, construction and maintenance of factory buildings and equipment. Good opportunity with large growing company, desirably situated. Location New York. 977.

PRODUCTION ENGINEER, must have thorough factory experience on motor-truck construction, organization, production, equipment and accounting. Live wire. State age, experience and salary desired. 988.

DRAFTSMAN, technical graduate, familiar with design of power-station installations, steam piping and fair amount of structural work. State age and experience. Location Brooklyn, N. Y. 990.

MECHANICAL ENGINEER having had technical education and at least five years' experience in plants manufacturing chemicals. Work mainly advisory engineering work in connection with manufacture of chemicals. Address, E. I. duPont de Nemours & Company, Engineering Department, Wilmington, Del. 991.

DRAFTSMAN wanted immediately by Chicago rubber works. Ingenuity is prime requisite. To work from rough sketches of labor-saving appliances. Permanent. Salary $25 for six months, $35 for next six months, future advances contingent on ability. Describe physical condition and education, state months on previous jobs and approximate hours per month in each kind of duty. 992.

MEN AVAILABLE

Only members of the Society are listed in the published notices in this section. Copy for notices should be in hand by the 15th of the month, and the form of the notice should be such that the initial words indicate the classification. Notices are not repeated in consecutive issues.

ENGINEER desires position in connection with maintenance or production of railway rolling stock and equipment or production incident to national defense. At present employed. Twenty years' experience in design and construction of industrial and railway mechanical equipment. Highly specialized in practical application of applied science, locomotives, cars, trucks, boilers, engines, turbines, tanks and special machinery, shop layouts and power plants, towers and structural work. E-158

MECHANICAL ENGINEER, 27, at present employed as assistant master mechanic with large packing company. Experienced in power-house design and layouts with refrigerating machines and steam plant; also general packing-house building, machine repairs and layouts. E-159

MECHANICAL ENGINEER, 30, M. E. graduate, practical shop, power-plant, drafting, plant maintenance, and production experience. Desires position in engineering, estimating, or maintenance department of reliable concern. Location immaterial. E-160

STUDENT MEMBER, 22, will graduate in June in mechanical engineering, University of Michigan. Desires position as assistant to chief engineer, production manager, or superintendent for manufacturing concern, preferably Ohio or Michigan. Has had experience in drafting and office work. Will furnish references. E-161

MECHANICAL ENGINEER, 28, desires junior partnership or interest in consulting or contracting firm. Will make investment or consider position on salary. University graduate, 3 years' experience, one year in Europe, in power-generation design and construction, industrial-plant design, investigations. Would consider locating permanently in Europe, particularly Russia. E-162

SUPERINTENDENT or CHIEF ENGINEER, 44, married, technical education. Twenty years' experience as chief engineer in brewery, railroad shops, largest stove foundry in world, and chemical works; manager electric light plant, superintendent foundry and machine shop, superintendent ice-machine factory, chief smoke inspector large city, and mechanical superintendent of hospital. Combustion engineering specialty. Desires position in large industrial plant or other responsible position. Highest references. Present salary $3600. E-163

RESEARCH ENGINEER. Assistant professor of mechanical engineering in leading university, ten years' continuous teaching experience, desires to engage for year in commercial research work, either in commercial laboratory or with power-generating equipment. Experience previous to teaching includes several years' commercial engineering and two years' sales work. Would consider instructional work in another school. E-164

MASTER MECHANIC, 29, M. I. T. graduate, '11. Selling experience. At present employed. Open to any live proposition with chance to progress. E-165

PUBLIC-UTILITY VALUATION ENGINEER, 27, M. I. T. graduate. Desires change from present position to one offering more opportunity for advancement. Three years' extensive experience inventory and appraisal water, gas, electric, traction, and telephone public utilities in East, as mechanical engineer in appraisal department of state public utility commission. Thoroughly familiar with efficient methods of construction and management of above corporation. Special training with unit-cost studies, estimation of annual and accrued depreciation and overhead charges. Author of technical articles on overhead charges and depreciation. Good draftsman. Capable taking charge field or office valuation department. Unmarried. Salary about $2000. E-166

ASSISTANT TO ENGINEER OR SUPERINTENDENT. Graduate mechanical engineer, 22, shop and estimating experience. Seeks position of some responsibility, with good future. Location preferred, Eastern States. E-167

MECHANICAL ENGINEER, graduating from well-known university in June, desires position with future, preferably in connection with consulting engineer's office. References given. E-168

INDUSTRIAL ENGINEER, technical graduate, 31, desires position as general superintendent or works manager in moderate-size plant with view to making permanent connection. At present employed as industrial engineer by large Eastern manufacturing corporation; work

nearing completion with this concern after six years' service. Wide experience in purchasing materials, employment of all classes of labor, design and layout of factories, and installation of scientific production methods, standardization and management in various industrial plants. E-169

FOUNDRY MANAGER or SUPERINTENDENT. Practical foundryman, capable of filling any foundry position. Charge of some of largest foundries in country for past 15 years. Best references as to ability. E-170

PLANT ENGINEER. Graduate mechanical engineer, with good practical experience in design, operation, and maintenance of industrial machinery and power plants. Specialized in combustion of anthracite and bituminous coals and generation of cheap power. Experienced in use of electricity in manufacturing plants. Location New York or vicinity. E-171

MECHANICAL ENGINEER, 15 years' experience in power plant and factory design, 10 years in responsible charge, now completing installation of power plant out of town, wishes to return to New York City. Accustomed to take full charge of design, purchase of apparatus and material, supervise construction, etc. Experience includes factory production and special tool design. Salary $3000-$4000. E-172

PROFESSOR OF MECHANICAL ENGINEERING desires work during vacation, from June 1 to September 20, teaching or practical work. Has had machine shop and drafting experience. E-173

MECHANICAL ENGINEER, 30, married, desires position with consulting engineer or as works engineer of medium-sized industral plant. Experience on steam-power plant and industrial-plant design and maintenance. E-174

MANUFACTURER'S REPRESENTATIVE. Graduate engineer maintaining engineering office in Twin Cities desires to represent manufacturer of mechanical line in Northwest. E-175

HIGH-SCHOOL HEAD OF DEPARTMENT. Technical and college graduate. Seven years in present position. Five years' shop experience. Employed at present, but desires to make change at end of semester. E-176

PRODUCTION ENGINEER. Graduate M. E. One year preliminary training with well-known firm of efficiency engineers, backed up by 5 years' practical experience in several industries. Have installed and operated cost systems, and organized and supervised work of planning departments. Competent organizer along modern lines, capable executive, and can handle men and produce results. Employed at present, but desires to form new connections, preferably as assistant to factory manager. E-177

PROFESSOR OF MECHANICAL ENGINEERING, technical graduate, 17 years' experience in teaching, engineering and consulting work. Practical experience in commercial engineering; specialized in steam-power plants. Head of department of mechanical engineering in leading university for number of years, and at present head of departments of mechanical and electrical engineering in university of good standing. Location abroad, China preferred. E-178

SUPERINTENDENT or EQUIPMENT ENGINEER. For past two years with large rifle works, in charge of installing equipment, manufacturing and heat treating. Thorough knowledge of modern methods for producing interchangeable parts. E-179

YOUNG TECHNICAL GRADUATE in mechanical engineering, with two years' general shop practice, wishes to change from present position. E-180

MECHANICAL ENGINEER, 30, university graduate. Five years' experience in factory layout, construction, power-plant design, heating and ventilating. Familiar with modern methods of factory and power-plant operation. Desires position as chief engineer or works engineer with manufacturing plant. Salary $250 per month. E-181

ASSISTANT SUPERINTENDENT, PRODUCTION ENGINEER, MAINTENANCE SUPERINTENDENT, CHIEF TOOL DESIGNER. Twenty years' practical experience in shop and drafting room as machinist, master mechanic, shop foreman, tool designer, chief draftsman. Design and supervision of construction tools, labor-saving devices, routing factory layout, installation and maintenance of equipment. Now employed as chief draftsman in munition plant. Seeks position with future. Location immaterial. E-182

MECHANICAL and ELECTRICAL ENGINEER. Technical graduate, 28. Four years in production and engineering; engines, pumps, compressors, motors, and generators. Three years' municipal work, electrical and gas. E-183

ENGINEER and SUPERINTENDENT. Cornell graduate, with extensive experience in designing, purchasing, constructing and operating power plants, track work transmission lines, distribution lines, car barns, office buildings, foundries, machine shops, chemical plants, tanneries, cotton mills, gun cotton and smokeless-powder plants, factories of reinforced concrete, flat slab or mill construction, also structural-steel docks, piling, sewers, and artesian wells, heating and drying systems. E-184

ASSISTANT TO PURCHASING AGENT. Varied practical and office experience, engineering materials, electrical and mechanical equipment and matters pertaining to construction. E-185

MECHANICAL ENGINEER. Stevens graduate, 26, married. Experience in steel-rolling mill. Desires position as works engineer. At present employed. East preferred. E-186

EXECUTIVE, until recently connected with one of Detroit's largest automobile concerns, desires responsible position. Experienced in modern methods of economical, intensive manufacturing. Competent to organize and handle large bodies of men. Selling experience this country and abroad. Salary $10,000 to $15,000, depending on character of employment offered. E-187

AUTOMATIC MACHINE DESIGNER, experienced in designing special machinery to economize labor and facilitate production. Has inventive faculty. Could reduce cost and increase production of plants manufacturing specialties. Permanent employment not required, but will study problems, make suggestions, and design special machines, tools, and attachments. Available about June 1. E-188

GRADUATE in mechanical engineering, '14, two years' experience in general testing work, with some machine-shop and foundry experience, desires position as testing engineer or assistant to engineer in charge of power plant operation. E-189

GRADUATE M. E., 25, Chinese, one and a half years' experience in shops and office, desires situation with aeroplane company or manufacturing concern with commercial interests in the Far East. E-190

MECHANICAL ENGINEER or ASSISTANT SUPERINTENDENT, technical education, 31, married. Twelve years' experience in manufacturing plants as toolmaker, toolmaker foreman, machine designer, chief draftsman, factory superintendent, and now as mechanical engineer in large rifle factory. Fully conversant with interchangeable manufacture. Salary $2600 per year. E-191

MECHANICAL ENGINEER. Technical graduate, 12 years' practice, desires change. Especially experienced in modern methods of boiler-room operation and maintenance, designer on heavy machinery, designer and engineer of construction on steel-frame buildings, plain and reinforced concrete. Experienced executive. E-192

ASSISTANT SUPERINTENDENT or EXECUTIVE, American, 36, technical education. Twelve years in drafting room, including chief draftsman; six years' shop experience, one as foreman. Practical mechanic, familiar with design of special machinery, tools, jigs, fixtures, etc., for manufacturing duplicate parts on interchangeable system. Salary $2000 per annum. Location preferred, Eastern States. E-193

EXPERIMENTAL or WORKS ENGINEER, RESEARCH ENGINEER, PROFESSOR OF MECHANICAL ENGINEERING. Experienced mechanical and civil engineer, now engaged in munition manufacture, open for engagement. Graduate of leading university, also member S. A. E., experienced in teaching and engineering work of all kinds. Would locate in England or France. E-194

DESIGNING ENGINEER, 30, married. Ten years' English and American experience in commercial trucks, tractors and motor fire apparatus; exceptional experience on front-wheel-drive trucks and interchangeable manufacture. Associate Member M.I.M.E. Minimum salary $2400. E-195

MECHANICAL ENGINEER, ten years' experience in coal and power-plant testing, and design and use of instruments for obtaining highest economy. Desires position with consulting engineer or testing department of large operating company. E-196

FUEL ENGINEER. Graduate M. E., 28. Three and a half years' shop experience. Three years with anthracite and bituminous coal mining companies; mining, preparation, sales, specifications, contracts, laboratory, and power plant testing. Experience with Federal Bureau of Mines and consulting engineers. At present employed. E-197

COLUMBIA GRADUATE, M. E., two years' experience in production and inspection departments, both in shop and in office, would accept position near New York City offering opportunity for advancement. Salary to start $1300. At present employed. E-198

ENGINEERING SURVEY

A Review of Engineering Progress and Attainment in Mechanical Engineering and Related Fields, Including a Digest of Current Technical Periodicals and a Selected List of Engineering Articles

THE scope of the Engineering Survey has now been extended to include a monthly review of progress and attainment in the mechanical engineering and related fields, in accordance with plans developed by the Publication Committee. In this number, issued at the beginning of our participation in the great war, foremost attention is given to the agencies through which engineers are working in coöperation with the Government *to bring the war to a successful issue.* These are mainly comprised by the Naval Consulting Board, the National Research Council, the Advisory Commission of the Council of National Defense, the Federal Shipping Board, and the National Advisory Committee for Aeronautics: together with the various sub-committees and boards organized under the direction of these major bodies. The constitution and objects of these organizations are described, as well as some of their most important accomplishments to date.

The Naval Consulting Board

THE first concerted effort toward coöperation between the Government and civilian engineers in this country was made in 1915 when Secretary Daniels of the United States Navy Department invited eleven engineering and scientific societies to form an advisory board of 23 members, constituting the Naval Consulting Board, headed by Thomas A. Edison. The American Society of Mechanical Engineers was represented on this board by 12 members, two, W. L. R. Emmet and Spencer Miller representing it officially.

The Naval Consulting Board resolved itself into committees, one of which, headed by Howard E. Coffin, Mem.Am.Soc.M.E., was the Committee on Production, Organization, Manufacture and Standardization. This Committee formulated a plan for a census and classification of the manufacturing establishments of the country which was effected through individual and painstaking work by members of the National Societies of Civil, Mining, Mechanical and Electrical Engineers and the American Chemical Society. A director for each State in the Union was appointed by each society, whose immediate work was to obtain an accurate inventory of the facts necessary to be known to the Army and Navy about the capabilities of our Nation to supply munitions in case of war.

This great work was carried through successfully and the returns received from 27,000 of the larger plants showed most impressively the almost unlimited resources which Industrial America is now able to place at the disposal of the Government for the prosecution of the war.

The data collected by the Committee on Industrial Preparedness of the Naval Consulting Board have been turned over to the Council of National Defense, where they are at the disposal of Director Walter S. Gifford, who had charge of the tabulation of the statistics as they were accumulated by the Committee on Industrial Preparedness.

The Naval Consulting Board is now devoting its attention mainly to passing judgment upon inventions submitted to the War and Navy Departments, so that the Nation may not only have the advantage of the work of its inventive citizens, but also will be shielded from having to consider worthless or unpromising inventions. The Secretary of the board is Thomas Robins, 13 Park Row, New York.

National Research Council

THE National Research Council of the National Academy of Sciences was formed at the request of the President of the United States in September 1916, for the promotion and furtherance of scientific research. The conception of the National Research Council is due to Dr. George E. Hale, Director of Mount Wilson Solar Observatory, who has visited Europe in order to obtain information upon the steps that were being taken in England and France in research and in coördinating the activities of scientific men for the purposes of war.

The officers of the Council are: Chairman, George E. Hale; First Vice-Chairman, Charles D. Walcott; Second Vice-Chairman, Gano Dunn, Mem.Am.Soc.M.E.; Secretary, Cary T. Hutchinson, Mem.Am.Soc.M.E., the office of the Secretary being in the Engineering Societies Building, New York. The Chairman, Dr. Hale, was authorized to appoint an executive committee to consist of ten members, in addition to the President of the National Academy of Sciences, Dr. William H. Welch, the Chairman and the two Vice-Chairmen. Dr. Hale appointed the following members: J. J. Carty, Russell H. Chittenden, Edwin G. Conklin, Gano Dunn, Mem.Am.Soc.M.E., Robert A. Millikan, Arthur A. Noyes, Raymond Pearl, M. I. Pupin, S. W. Stratton, Mem.Am.Soc.M.E., and Victor C. Vaughan.

The work of the Council has been carried on by the Executive Committee, which has held twelve meetings, the outcome of which is principally the appointment of a number of committees to report upon and organize research in different branches of science.

Military Committee. First in importance is the Military Committee for governmental research requirements, composed of three representatives of the Army, General Gorgas, General Crozier and General Squier, the heads, respectively, of the Medical, Ordnance, and Signal Corps Departments of the Government: of four representatives of the Navy, Admirals Taylor, Griffin, and Earle, and Dr. Gatewood, the heads, respectively, of the Construction, Engineering, Ordnance, and Medical Departments of the Navy: and of the heads of certain civilian bureaus of the Government. This committee will operate more or less independently.

Census of Research. This committee, acting under Dr. Stratton, is preparing to make a census of all research men and materials in the United States.

Research in Industrial Institutions. This represents an undertaking of great importance, under the direction of Mr. Carty. This committee expects to devise means by which the smaller industries can have the advantage of scientific re-

[illegible] through some scheme of coördination and the employ-[illegible] of some existing research means for the purpose of [illegible] the work itself.

Nitrate Supply Committee. This committee is directed by Dr. A. A. Noyes, and it has already done noteworthy work. It has been asked to advise the Government regarding the expenditure of $20,000,000 that Congress has appropriated for the purpose of providing a supply of nitrates; hence its work has an immediate practical bearing.

The personnel of an Engineering Committee is now being completed, as explained in the Society Affairs section of this number in the communication from Mr. Gano Dunn.

The Engineering Foundation, which is administered under the auspices of the United Engineering Society and the national Societies of Civil, Mining, Mechanical and Electrical Engineers has placed its funds at the disposal of the National Research Council for organization and operation expenses.

The National Research Council is maintaining close relations with the Council of National Defense in its work and preparation for the industrial activity which will accompany the prosecution of the war.

Council and Advisory Commission of National Defense

COINCIDENT with the Naval Consulting Board there was in process of formation the Council of National Defense which was organized as a result of the act of Congress of August 29, 1916, "for coördination of industries and resources for the national security and welfare." It was "to consist of the Secretary of War, the Secretary of the Navy, the Secretary of the Interior, the Secretary of Agriculture, the Secretary of Commerce and the Secretary of Labor."

The act further provided for the appointment by the President of the United States of an Advisory Commission of seven members having "special knowledge of some industry, public utility or the development of some natural resources or be otherwise specially qualified.. . . ." Two months later, the Commission was appointed, as follows:

Daniel Willard, President, Baltimore and Ohio Railroad

Howard E. Coffin, Mem.Am.Soc.M.E., Vice-President, Hudson Motor Car Company

Dr. Hollis Godfrey, Mem.Am.Soc.M.E., President of the Drexel Institute

Julius Rosenwald, President, Sears, Roebuck and Company

Samuel Gompers, President, American Federation of Labor

Bernard M. Baruch, Financier

Dr. Franklin H. Martin, Surgeon

The members of the Advisory Commission serve in a consulting capacity without compensation and are in practically constant attendance at Washington.

The organization opens up a new and direct channel of coöperation between business and scientific men and all departments of the Government, and constitutes a rallying point for civic bodies working for the national defense. Among other functions defined by President Wilson are: (1) coördination of all forms of transportation and the development of means of transportation to meet the military, industrial and commercial needs of the case, and (2) the extension of the industrial mobilization work of the Committee on Industrial Preparedness of the Naval Consulting Board.

One of the chief objects of the Council is to inform American manufacturers as to the part they can, and must, play in the national emergency. It has established and maintained through subordinate bodies of specially qualified persons, auxiliary organizations composed of men of the best creative and administrative capacity.

The constitution of the Council and Advisory Commission of National Defense is as follows:

THE COUNCIL

The Secretary of War, Chairman; the Secretaries of the Navy, Interior, Agriculture, Commerce and Labor.

THE ADVISORY COMMISSION

Headquarters, Munsey Building, Washington, D. C.

Daniel Willard, Chairman; and Messrs. Baruch, Coffin, Godfrey, Gompers, Martin, and Rosenwald as enumerated above.

Director of the Council and of the Advisory Commission, Walter S. Gifford.

Secretary of the Council and of the Advisory Commission, Grosvenor B. Clarkson.

Chief Clerk and Disbursing Officer, E. K. Ellsworth.

COMMITTEES

1 Transportation, including railroad and motor transportation, and Communication, Daniel Willard, Chairman.

2 Munitions, Manufacturing, including standardization and industrial relations, Howard E. Coffin, Chairman.

3 Raw Materials, Minerals and Metals, Bernard M. Baruch, Chairman. Sub-Committees: Oil, Wool, Steel, Nickel, Copper, Leather, Rubber, Brass and Aluminum.

4 Labor, including conservation of health and welfare of workers, Samuel Gompers, Chairman.

5 Supplies, Clothing, etc., Julius Rosenwald, Chairman. Sub-Committees: Cotton Goods, Woolen Goods, Shoes and Leather.

6 Science and Research, including engineering and education, Dr. Hollis Godfrey, Mem.Am.Soc.M.E., Chairman: Dr. Henry E. Crampton, Vice-Chairman.

7 Medicine, including general sanitation, Dr. Franklin H. Martin, Chairman.

COMMITTEES OF ADVISORY COMMISSION

The Transportation Committee mentioned above was organized under the direction of Daniel Willard, with the assistance of the American Railway Association which met in conference at Washington and nominated members for the committee. There are four sub-committees working with the Department Commander in each of the four military divisions of the country, to provide for rapid transportation of troops and supplies in times of emergency. Another sub-committee has been formed representing the leading telephone and telegraph companies of the country, headed by Theodore A. Vail. A Motor Transport Committee, headed by Alfred Reeves, General Manager of the National Automobile Chamber of Commerce, has been appointed for the purpose of mobilizing the motor vehicle resources of the country for emergency purposes.

The Munitions Manufacturing Committee, of which Howard E. Coffin, Mem.Am.Soc.M.E., is Chairman, supervises the work of sub-committees on munitions, and all matters pertaining to the selection of manufacturers for the production of munitions, and assists manufacturers in getting out the work properly and without delay. An aircraft board coming under the general direction of this committee is now being formed.

The Raw Materials Committee has been estimating the amount of materials that would be needed to put an assumed force of one million men in the field and the provisions and supplies required for each 90 days of service. Sources of

supply are to be studied and it is expected to be able to determine in advance any deficiencies which may exist in the resources of the country. This committee, at the instance of Mr. Baruch, has secured action whereby copper will be supplied to the Government at 16 2-3 cents per lb. and steel at greatly reduced prices.

Committee on Labor. Mr. Samuel Gompers, as Chairman, is working in coöperation with Mr. Coffin whose committee is charged, among other duties, with the question of industrial relations and proper method for building up an industrial reserve. Whereas a soldier may be made in a few months, it requires a corresponding number of years to make a skilled mechanic. Mr. Coffin has recently remarked that "in modern warfare the blood of the soldier must be mingled with three parts of the sweat of the man in the mills."

Committee on Science and Research, under the direction of Dr. Hollis Godfrey, Mem.Am.Soc.M.E., has been working out a fundamental plan for education in the higher institutions of the country during the period of war which, however, is primarily as a basis for peace. This plan considers, among other matters, the placing of emphasis on such branches of engineering or other subjects as pertain to the efficient production of materials of war, or to efficient work on the part of young graduates entering into Government service. This committee, also, enlists the service of engineers in whatever capacity they may be needed by the Council during the period of the war. Other developments of this committee are now reaching the point of publication and will be referred to from time to time.

SUB-COMMITTEES AND BOARDS

There have also been various sub-committees and boards appointed by the Council and Advisory Commission, of which the following are of the greatest interest to engineers:

Munitions Standards Board, under the general direction of the Munitions and Manufacturing Committee, dealing, in coöperation with the Government, with drawings and specifications, jigs, fixtures, etc.; Frank A. Scott, Mem.Am.Soc.M.E., Vice-President, The Warner and Swasey Company, Cleveland, O., Chairman. The other members are:

William H. Van Dervoort, Mem.Am.Soc.M.E., President, Moline Automobile Company, Moline, Ill.

Edward A. Deeds, Mem.Am.Soc.M.E., President, The Dayton Engineering Laboratory Company, Dayton, O.

Francis C. Pratt, Mem.Am.Soc.M.E., Assistant to President, General Electric Company, Schenectady, N. Y.

Samuel M. Vauclain, Mem.Am.Soc.M.E., Vice-President, The Baldwin Locomotive Works, Philadelphia, Pa.

John E. Otterson, Mem.Am.Soc.M.E., Vice-President, Winchester Repeating Arms Company, New Haven, Conn.

This Board, with other agencies, is bringing to the War and Navy Departments the knowledge acquired by the manufacturers of the country in making munitions for foreign governments, and other expert knowledge regarding the requirements for quantity production which is essential in the preparation of the proper drawings and specifications by the War Department. It is adapting peace-time standards to war-time conditions and endeavoring to avoid the difficulties of production which were encountered at the outset by the Allies. At that time Germany was the only country which had the methods of manufacture carefully worked out in detail. The experience of the belligerent countries in these matters is invaluable.

An important sub-committee of this board relates to small arms and ammunition, of which J. E. Otterson is Chairman. Like the larger committee, this one is endeavoring to coördinate the ideas of manufacturers and of the Government experts to standardize materials and design as far as practicable under the existing emergency conditions. Consideration is being given to the use of manufacturing facilities as they now exist as a result of the orders placed by foreign governments, in order to render the promptest service possible.

It is expected that the Government will accept foreign designs in some instances at least, in order to insure more prompt delivery through the utilization of components, dies, fixtures, etc., that are already in existence and in working order. Where designs can be changed to conform to United States Government standards without causing material delay in delivery, this will probably be done. In the case of rifles, a foreign design has been proposed; but in the case of cartridges, it is likely that the Government will require the United States Government cartridge.

General Munitions Board. Following the appointment of the Munitions Standards Board, there was formed a General Munitions Board headed by Frank A. Scott, Mem.Am.Soc.M.E., and comprising in its membership seven representatives of the Army, eight of the Navy, besides Messrs. Baruch, Coffin, Rosenwald and Martin of the Advisory Commission. The Secretary is Chester C. Bolton. The officers serving on the Board were designated by the chiefs of the several departments and bureaus, under authority of the Secretaries of War and of the Navy.

The purpose of the board is to assume the prompt equipping and arming of whatever forces may be called into the service of the country with the least possible disarrangement of normal industrial conditions. Its immediate efforts will be directed toward coördinating the making of purchases by the Army and Navy, to assist in the acquirement of raw material and manufacturing facilities and to establish the precedence of orders; but it is not intended that the board shall have authority to issue purchase orders or to bind the Government in contracts for purchase.

Commercial Economy Board, of which A. W. Shaw, President of A. W. Shaw Company, is Chairman, and Dr. Hollis Godfrey, Chairman of the Committee on Science and Research, is a member. This board is designed to meet in advance problems of war-time distribution and to bring business men together in a scheme of voluntary coöperation to eliminate waste by adopting commercially efficient methods: In short, to nationalize distribution.

Food Board, the Chairman of which is Herbert C. Hoover, Mining Engineer and head of the American Commission for Relief in Belgium. At the time of his appointment, Mr. Hoover sent from abroad, by Associated Press, a strong statement of the needs and opportunities of such a board. He has instituted an inquiry abroad into the methods used to control prices and for the elimination of speculation. From the fact that America must become the food source for a large part of the world's population, he proposes that the Food Board shall take such guiding action as may be necessary to increase the production of food, to conserve as well as to increase farm labor, to instill a willingness for the elimination of waste, to control the exportation of food and to prevent speculation or undue profits.

SIGNIFICANCE OF THE ADVISORY COMMISSION

The importance of the work which the Advisory Commission is accomplishing in this crisis in the Nation's history is per-

[illegible] not fully realized by the engineering public. Legally, the Advisory Commission has no executive power; in point of fact it has at its command information to supply the Nation with the same service that is rendered to the British nation by the representative business men appointed by Mr. Lloyd George's cabinet for the war reorganization of the British industries. While Mr. Willard, the Chairman of the Advisory Commission, is not the equivalent of the British Minister of Munitions, the service which he is rendering in the capacity of chairman is entirely comparable to that of the British minister, save the legal authorization to enforce his recommendations. The plan is American in its conception and administration. It is believed that as the duties of the commission are now organized no additional cabinet positions will be required in the conduct of the war, since, by informal extension of the power granted to Mr. Willard and his colleagues, as occasion may demand, the growing activities of the Government will be amply provided for.

National Advisory Committee for Aeronautics

Another important board is the National Advisory Committee for Aeronautics, organized under Act of Congress of March 3, 1915, from representatives of Government departments and expert engineers and scientists nominated by the President.

The board as at present composed consists of the Secretary of the Smithsonian Institution, Dr. Charles D. Walcott; the Director of the Bureau of Standards, Dr. S. W. Stratton, Mem.Am.Soc.M.E.; the Chief of the Weather Bureau, Prof. Charles F. Marvin; two officers of the Navy, two officers of the Army, and an officer of the Treasury Department. These representatives of Government bureaus are supplemented by four scientists at large, namely, Prof. Michael I. Pupin, of Columbia University; Prof. Joseph S. Ames, of Johns Hopkins University; Prof. John F. Hayford, of Northwestern University, and Prof. William F. Durand, Mem.Am.Soc.M.E., of Leland Stanford Junior University, Chairman.

Shortly after its organization the National Advisory Committee entered into an arrangement with various industrial companies specializing in aeronautical supplies and with several universities to conduct investigations on various matters of importance in the new art. Thus an investigation on pitot tubes was entrusted to the Bureau of Standards, and the Weather Bureau was commissioned to undertake the preparation of a report on the problem of atmospheric conditions in relation to areonautics.

The John A. Roebling Sons Co. undertook an investigation of aviation wires and cables. The Goodyear Tire and Rubber Co. was asked to investigate the relative worth of improved fabrics, and the United States Rubber Co. the allied subject of balloon and aeroplane fabrics.

At Leland Stanford Junior University an aeronautics laboratory was equipped and extended experiments are under way on the performance of different designs of propellers. Finally, Columbia University was given the difficult and important subject of thermodynamic efficiency of present types of internal combustion engines.

The reports of the advisory committee as a whole, and the various organizations entrusted with special investigations, in so far as they have been published, represent contributions to the science of aviation of the greatest value. Thus, Report No. 11, entitled *A Preliminary Study of the State of the Art of Carburetor Design*, prepared by Charles E. Lucke, Mem.Am. Soc.M.E., Professor at Columbia University, is a volume of 552 pages, probably the most complete and exhaustive study of carburetor design and performances available in any language.

Since the formation of the National Advisory Committee it has acted as the central source of information and research, as well as the clearing-house on all work on aviation carried on by the Government. In addition it has done valuable work in bringing together manufacturers of aircraft and accessories and officials of the Government interested in the progress of aviation. These conferences have been of great value in clearing up the ideas of all concerned.

The Advisory Committee has also done yeoman service in developing aviation in connection with the work of the Post Office and Treasury Departments. At present it is actively collaborating with the War and Navy Departments and the Council of National Defense.

Federal Shipping Board

Of the civilian organizations, other than those already mentioned, which are rendering expert service to the Government, the most important and far-reaching in its probable effect on the war is the Federal Shipping Board. This board was organized as a result of the Ship Purchase Bill of August 1916, and the names of its members were sent to the Senate by President Wilson in December 1916. William Denman, Merchants' Exchange Building, San Francisco, is the chairman of the board.

As very fully announced in the daily press, plans are being completed for the construction of wooden cargo vessels on a gigantic scale, to be leased to citizens of the United States for operation in foreign trade.

On April 17 the United States Shipping Board Emergency Fleet Corporation was chartered in the District of Columbia, with a capital stock of $50,000,000, the amount authorized by Congress for the Shipping Board to spend on ships. It is now announced that a bill will be introduced into Congress to increase the capital stock to $225,000,000.

Major General Goethals, at the direction of President Wilson, has agreed to supervise the building of the ships, and in view of the national call upon his services has been released by Governor Edge of New Jersey from his contract to supervise the $15,000,000 expenditure for reconstructing the highways of that State.

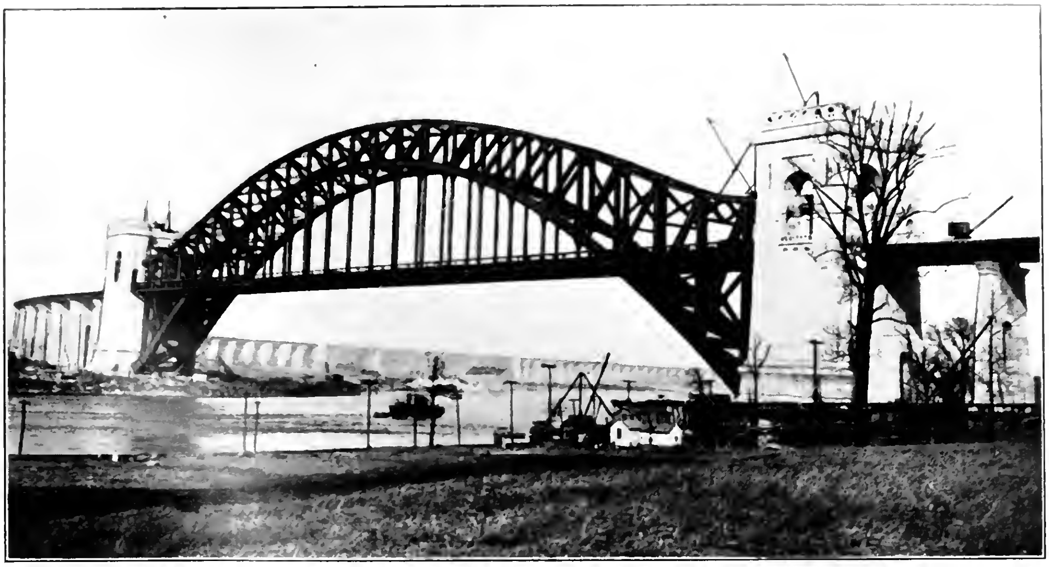
The wooden ships are to be of 2000 to 3500 tons displacement and will probably be equipped for oil burning. The ships and engines will be standardized as far as possible, and the boats will carry a crew of about thirty men, will be equipped with wireless, and armed for protection against submarines.

It is expected that the first of the vessels will be ready in about six months. The Shipping Board estimates that 150,000 men will be needed to complete the building program in the time determined on, and upward of 100 private plants will be engaged.

As The Journal goes to press announcement is made of a newly-created Shipping Committee of the Council of National Defense, with William Denman, chairman of the Shipping Board, at its head. This committee will work in coöperation with the Transportation Committee to facilitate transportation by rail wherever it seems wise to transfer coastwise vessels to trans-Atlantic service.

Opening of Hell Gate Bridge

THE engineering event of the month, from the standpoint of transportation, was the opening to traffic on April 1 of the Hell Gate bridge, the masterpiece of Dr. Gustav Lindenthal, chief engineer, which forms the final link of the New York Connecting Railroad between the New York, New Haven and Hartford and the Pennsylvania systems.



THE GREAT ARCH OF THE HELL GATE BRIDGE. IN THE BACK GROUND IS SEEN THE LONG APPROACH ON THE NEW YORK SIDE

For years New York City may be considered to have been the *dividing point* in the railway lines radiating from it in all directions. Both passengers and merchandise arriving in New York from the South or West had to be transferred in order to go East and North.

The building of the Pennsylvania Station on Manhattan and the construction of the tunnel under the East River to connect with the Long Island Railroad was the first step in the project for through trains and to reduce the ferry distance for the transshipment of freight at New York.

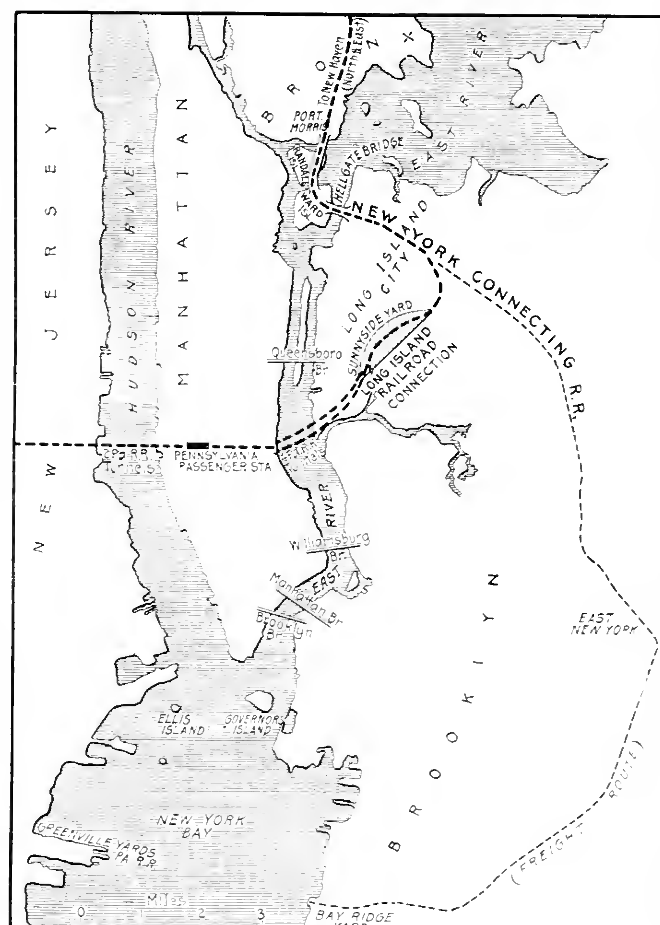
The course of the New York Connecting Railroad is indicated on the map. At 142d Street in the Bronx the line leaves the N. Y., N. H. & H. R. R. tracks, spans one after another the Bronx Kill and Little Hell Gate, and crosses Randall's Island and Ward's Island to the west shore of the East River, after a sweeping curve on the way. From the east shore of the East River the Connecting Railroad continues through Long Island City and then turns to the west, joining the Pennsylvania tracks at the Sunnyside yard. While passenger trains pass through the tunnels and under Manhattan en route to the West or East, freight is to go by belt line around Brooklyn to Bay Ridge on New York Bay, convenient of access by car ferry from the Pennsylvania terminal at Greenville, N. J.

The bridge and viaduct portions of the line from 142d Street in the Bronx to Sunnyside yard on Long Island was a difficult part of the construction. Three miles of it consist of steel spans on concrete piers, with one mile in fill, retained between high concrete walls held together by tie rods.

Apart from its importance as a traffic medium the Hell Gate bridge is also a remarkable engineering construction, if only because it has the longest and heaviest steel arch in the world. It is remarkable also for its beauty of outline, due to the collaboration between its designer and the architect, Henry Hornbostel. The following data are from the *Engineering News*:

Span, 1,016 ft. 10 in. between tower faces; [illegible] between centers of bearings.

Arch, height from center to end hinges to center of top chord



MAP OF THE NEW YORK CONNECTING RAILROAD

[illegible] at ends, 260 ft. at center. Height to [illegible] chord, 220 ft. Greatest height above mean high water, 310 ft. Clearance above mean high water, 210 ft.

Towers, height above ground, 240 ft.

Width, 95 ft. between centers of [illegible]; 60 ft. between centers of trusses.

Bottom chord 6½ ft. wide, 11½ ft. deep at ends, 7½ ft. deep at center; maximum section, 1384 sq. in.

Heaviest single piece, 185 tons (shipping weight 150 tons).

Load, the bridge carries four tracks on ballasted concrete floor; total dead load 52,000 lb. per lin. ft. of bridge; assumed live load, E 60 on each track.

Of unusual interest to mechanical men are the machine shop problems that were encountered because of the unusual size and weight of the bridge members. All holes and field connections were drilled to match before shipping, an undertaking of extreme nicety. The chord joints are polygonal-faced to secure uniform stress distribution and were planed. This necessitated having the roof of the planer house removable in order to handle the chords, for which latter purpose a 185-ton gantry crane was built.

N.Y. State Barge Canal to be Opened

By courtesy of Frank M. Williams, State Engineer, State of New York, the following data are published on the New York State Barge Canal, which will be opened on May 15 for through navigation between tidewater at Troy to Whitehall on Lake Champlain. The entire canal will be opened in May 1918, at which time through navigation will be available on the new channel between Troy and Tonawanda, where the Niagara River is entered and followed to Buffalo on Lake Erie. This summer, however, boats using the Erie will follow the new channel to a point north of Syracuse where the Oswego branch is encountered, and from there on to a point west of Rochester will have to use the old canal at places owing to the incompleted condition of the new channel. From Rochester on to Tonawanda the canal is completed.

Regardless of this feature, however, one boat line has awarded contracts calling for the construction of eight self-propelled barges each 150 ft. long and 22 ft. wide with a draft of 6½ ft. and a capacity of upwards of 600 tons. These barges are to be completed in 1918 and will be of steel construction with a wood lining which is calculated to protect the cargoes from heat. They will be driven by semi-Diesel fuel-oil engines.

Foremost among the various structures on the canal are the locks. These are all constructed of concrete and are operated by electricity which is generated at hydroelectric stations or gasoline-electric plants which are located on the various locks. A notable lock is that located at Oswego. This has a lift of 25 ft. and utilizes the siphon principle. It is the largest lock of this type in the world and the first to be constructed in this country. Four other locks of considerable note are those located at Lockport and Seneca Falls, there being a flight of two at each place, with a combined lift of each flight of 48 ft. The New York State Barge Canal has cost the State $150,000,000.00 to construct.

Curtis Bay Coal Pier at Baltimore

The new export coal pier of the Baltimore and Ohio Railroad at Curtis Bay, Baltimore Harbor, said to be the largest in the world, has a handling capacity of 12,000,000 tons a year, or a maximum of 7000 tons an hour, and is the first of its type. At the land end are two car dumpers, and on a concrete deck 8 ft. above mean tide are four loading towers and two trimming towers, to which coal is delivered by belt conveyors from receiving hoppers at the car dumpers or from the balancing bin interposed between the dumpers and the piers.

The tracks leading to the dumpers are on a descending grade, the cars running to the barney pit by gravity. The barney pushes the cars up the 10 per cent grade to the cradle of the car dumpers, where each, after being clamped, is turned upside down, delivering its contents to a counterweighted apron, which is raised when a car is being dumped, in order to minimize breakage. Each car dumper has three 60-in. belts with a capacity of 2000 tons an hour when traveling 500 ft. per min.

Each loading tower is equipped with a cage supporting a shuttle ram, and this cage may be raised or lowered to suit the height of the vessel being loaded, thus providing a further precaution against the breaking of the coal. The apparatus will load a hatch uniformly and reduce trimming to a minimum.

The two trimming towers, located on either side of the pier, have belts 48 in. wide with a capacity of 1500 tons an hour when the speed is 500 ft. per min. Coal for these belts is taken from the balancing bin. The trimming towers have 48-ft. swinging booms and are used for loading the bunker coal and also for finishing the slow work on a vessel, thereby releasing the loading towers for work on another vessel.

The functions of the tower are interlocked and controlled electrically, with push buttons located every 20 ft. on each belt-conveyor runway, and by pushing a button all movable parts of the belt, tower, and feeding are stopped. The operators are located in houses on the shuttles. The master control of the pier is located in the superintendent's office, enabling him to establish the maximum speed at which the belts are run.

The installation described here is interesting not only because of its large capacity and low drop, but also because it is the first attempt on such a large scale in this country at coal loading by mechanical means rather than gravity. (*Railway Review*, March 24, 1917.)

Huge Canadian Air Camp

Before summer, Canada will have a $5,000,000 aviation camp located at Camp Borden, north of Toronto, as reported by *Flying*, April, 1917. It will be the largest permanent establishment of its kind on this continent. Fifteen concrete sheds 120 by 66 ft., lighted and heated by electricity, are now being finished, and when the barracks are done, the camp will accommodate about 2000 men. This camp represents the first step taken by the Canadian Government in establishing its permanent air defenses, for which $80,000,000 are to be spent. Hitherto the greater number of aviators have been trained at Valcartier, but this camp will soon be given up for this kind of work, on account of the short season there, with its great amount of snow.

There will be 160 experienced military aviators constantly on duty at Camp Borden, either trained by the experts of the Curtiss Company, or selected from the 600 Canadian airmen now in service on the battle fronts of Europe. These 600 men form an available reserve of pilots, who have heard the shrapnel swish by them in actual battle, and know every detail of organization, as well as the work to be done in the air. Plans include training 5000 aviators, but it is not expected that the training of more than 2000 will be finished this year. As soon as pilots are graduated from the school they will be assigned to permanent camps, which will be scattered all over Canada. The localities of these camps, except Camp Borden, have not been announced.

Electric Propulsion on Battleships

THE recent decision to build battleships of the largest size with electric drive lends interest to the battleship *California,* of this general type, under construction at the New York Navy Yard. Her displacement is 32,000 tons and her maximum speed is to be about 22 knots, requiring about 37,000 shaft hp.

The equipment will consist of two turbine-driven generating units, four propelling motors, one for each shaft, two turbine-driven exciting units, and a complete equipment of condensing auxiliaries and ventilating blowers, all driven by motors from the exciting units.

The generators for the *California* are bipolar alternators, and the motors are arranged to be connected either for 24 poles or 36 poles. For economic cruising only one generator will be used, with motors on 36-pole connection. For higher speeds the 24-pole connection will be used.

Speed variation with either motor connection will be effected by change of turbine speeds through variable speed governors. This arrangement has been used in the *Jupiter* and entirely prevents racing.

Each of the auxiliary units is of 300 kw. capacity and a 240-volt direct-current generator geared to a high-speed non-condensing turbine. These turbines exhaust into the heaters, or main turbines, or both.

The steam consumption guaranteed on the *California* covers the total steam required for the main turbines and engine-room auxiliaries, at 250 lb. gage pressure, dry steam. The guaranteed water rates per hp. delivered to the propeller shaft vary from 14.6 lb. at 10 knots to 11.1 lb. at 19 knots.

W. L. R. Emmet, Mem.Am.Soc.M.E., in a paper read before the Society of Naval Architects and Marine Engineers in November 1915, gave the following comparison of steam consumption per effective hp. between the *California* as guaranteed, the *Florida* and *Utah*, which are driven by Parsons turbines, and the *Delaware,* which is driven by reciprocating engines.

POUNDS OF STEAM TO MAIN ENGINES PER HOUR PER E. HP.

	12 knots	15 knots	19 knots	21 knots	Prop. speed 21 knots
Florida	31.8	——	24.0	23.0	328
Utah	28.7	——	20.3	21.0	323
Delaware	22.0	——	18.7	21.0	122

Standardization of Army Trucks

THE Society of Automotive Engineers points out the vital importance of military motor transportation of troops and supplies. Tens of thousands of trucks will be needed for the armies now being organized in this country, and specifications covering important features of design and construction have been issued by the War Department and are appended to this note.

The standard truck is one of great capabilities, having a very low gear reduction and a large engine. Particular stress is laid on the inclusion of a four-speed transmission and on provision for adequate ground clearance, making possible negotiation of the roughest ground on which the trucks will travel. Demountable tires are considered essential owing to operations at points far distant from supply depots. Large gasoline tanks will be installed. Other items of interest are electric lighting, three-point engine suspension, locking differential, and large power-plant cooling capacity. Particular attention has been given to the spring suspension and the details of body construction. The gage of the wheels will be uniform. There is no doubt that trucks of different capacities excellently suited to the purpose of the Government have been specified. The Quartermaster and other corps of the War Department deserve great credit for this result.

The following are the principal features of the new truck:

Four-cylinder engine, 312 cu. in. piston displacement.
Poppet valves only.
Pressure lubrication.
Disk clutch.
Four speed transmission with low gear ratio of at least 40 to 1.
Preferably worm final drive.
Highest possible clearance, minimum at center about 11 in.
Some form of locking differential acting automatically to prevent wheel spinning.
Electric lighting equipment.
Radiator about twice the size normally used.
36 by 4-in. tires, must be demountable.

Interchangeability of radiators, gasoline tanks, and body-attaching devices are points, and the qualities of materials that must be used are specified, most strongly for such vital parts as the springs.

Submarine Chasers

INFORMATION has been variously published regarding the awarding of contracts by the Government for 110-ft. submarine chasers. The following specifications are condensed from an article to appear in *The Rudder* for May:

Contracts for the building of 345 of the 110-ft. submarine chasers have been awarded by the Navy Department. Of these 210 are to be built in private yards and the remainder in the Navy Yards. The Navy Yard in Brooklyn has started work and will have the first of this fleet ready by June 1. Nine more are to be completed by July 1, and after that ten are to be finished each month until the sixty are finished by December. The New Orleans Navy Yard is to build six, one a month after July 1; the Charleston Navy Yard, eight; the Norfolk Navy Yard, twenty-one; the Mare Island Navy Yard in California, fifteen, and the Puget Sound Navy Yard, twenty-five. These boats are to be built of wood, of 15-ft. beam and 4 ft. 6 in. draft.

The total cost of the 210 boats to be built outside the Government yards will be $10,741,063 and the average price of each boat so built is $51,100. The cost of engines, wireless, guns, fittings, etc., will be extra.

It was first planned to have the boats fitted with two slow-turning gasoline engines of 300 hp. each, giving a speed of 18 knots, but no engines of this type were available and it was decided to use three Standard Motor Construction Company's engines of 200 hp. each, and an 8-hp. engine for auxiliaries.

It is anticipated by builders that contracts may later be placed for boats of 80-ft. length, similar to those built in this country by the Elco Company, which recently completed an order for 550 for the British Government in the record time of 550 days. While boats of this length are undoubtedly less seaworthy than larger boats, reports of officers who have had charge of them in actual service praise highly their sea-going qualities. A marked advantage of the smaller size is the possibility of rapid production. In a boat up to 80 ft. in length, the great majority of parts can be handled by manual labor without the aid of cranes. In the construction of boats of larger size, a considerably larger number of elements must be handled by cranes, which materially retards production.

Inasmuch as the normal output in this country of large marine gasoline or oil engines probably does not exceed 250 a year, the question has been raised as to whether manufacturers of engines can keep pace with the construction of hulls for the submarine chasers, if put out in large numbers. The Journal has made inquiry regarding this among builders of such engines, who maintain that they will be able to meet probable demands. Estimates are more or less futile, because it cannot be predicted what will be the labor conditions or the possibility of procuring machine tools. The Elco Company had 1100 engines constructed for it in less than two years time.

The Engineering News Record

The consolidation of the *Engineering News* and the *Engineering Record* as a result of the merging of the Hill Publishing Company and the McGraw Publishing Company, brings together into one influential publication, two of the oldest technical periodicals. The combined "Engineering News-Record" appeared on the 5th of April.

The Engineering News was founded in 1874 when George H. Frost published the first copy of the Engineer and Surveyor. The next year the name was changed to the Engineering News. Prominent names successively associated with the journal are D. McN. Stauffer, Arthur Mellen Wellington, and in 1895 Charles Whiting Baker, who has since been its editor and is now the editor-in-chief of the *Engineering News-Record*. In later years, Mr. Frost repurchased a two-thirds' interest in the paper and in 1911 sold the journal to the Hill Publishing Company.

While the Engineering News has always been a paper devoted to civil engineering, the Record until recent years has been more in the field of heating, ventilation and sanitary engineering. It was founded in 1877 by Henry C. Meyer as the Plumber and Sanitary Engineer. It later became known successively as the Sanitary Engineer, the Engineering and Building Record and the Engineering Record.

After conducting the paper for 25 years, Major Meyer sold it to James H. McGraw. In 1902 John M. Goodell became the editor and in 1912 E. H. Mehren, who is now the general manager of the combined McGraw-Hill Publishing Company, was appointed in his place.

The *Iron Trade Review* calls attention to a rather perplexing situation which exists at present in the steel market. Inspection of the quotations reveals the surprising fact that some finished products apparently sell for less than the cost of the raw material from which they are made, and that this selling price seemingly bears but little relation to the cost of manufacture. Thus wire rods are quoted at $75.00 to $85.00 per ton, Pittsburgh. Plain wire made through many processes from the wire rod is quoted at $63.00 per ton, while nails made from this wire are quoted at $64.00 per ton. Plates are selling at $95.00 per ton and sheet bars, which in effect are narrow thick plates, are quoted at $65.00 per ton. Steel bars are $67.00 per ton, while angle bars, which are only bars with holes punched in them, sell at $55.00 per ton. This apparent inconsistency is in part explained by the fact that bars, sheet bars, and other partly finished steel are being bought for delivery in months hence at the quotations named. Wire and nails and sheets now being sold will be made from material bought a month ago at less than present prices.

News of Other Societies

Committee on Engineering Cooperation

Third Conference

The third annual conference of the Committee on Engineering Coöperation was held in the rooms of the Western Society of Engineers, in Chicago, on March 28 and 29. More than forty delegates, representing societies with a membership aggregating 50,000, were in attendance, and at the banquet, which was held on the evening of the second day, nearly 300 were in attendance, representing the members of the engineering societies in Chicago and vicinity.

On the first day, as each society was called, the delegate made an individual response. This was followed by specific papers, one by Mr. W. L. Saunders, Mem.Am.Soc.M.E., on the proposed Civic Scientific Alliance, and the Functions of Engineers' Clubs as illustrated by the Engineers' Club of St. Louis, by past-president F. G. Jonah.

On Thursday afternoon, Dean Potter, of the Kansas State Agricultural College, gave a report on the Land-Grant Colleges. There was also a remarkable address by President J. F. Dennis of the Canadian Society of Civil Engineers, and vice-president of the Canadian Pacific Railway, on the relation of the engineering societies to the war. The resolution, which was adopted with respect to coöperation, is as follows:

RESOLVED, That this conference requests and urges the national engineering societies in designing the engineering council to give consideration to, and create as soon as proper deliberation may permit, the machinery necessary to provide for a general permanent body of representatives of the various national, state and local organizations of the country in the interest of the common welfare and advancement of the profession as a whole.

This refers to the report of a sub-committee on the activities which the engineering societies are urged to undertake, as is shown in the following:

1. National Societies. As a preliminary to all efforts toward coöperation among existing engineering organizations there should be the expressed intent to assist in strengthening and unifying the work of the national engineering societies in the advancement of engineering knowledge and practice and the maintenance of high professional standards.

2. Local Organizations. The invigorating of local societies is fundamental because of the fact that while the great national societies are important in setting standards and in considering broad problems, yet local affairs make up at least nine-tenths of the vital problems of the engineer's life. In each locality where there may be a dozen or more engineers so situated as to be able to meet occasionally, there should be formed, if not already existing, an engineering association embracing all professional engineers and others interested in engineering to discuss and act upon these vital problems.

3. Home Rule. Each local engineering society should be autonomous or self-governed, wholly free in its activities from any dictation or control by other association or connections, fully adapted to local needs and conditions, and exemplifying in its activities the principle of complete home rule.

4. Welfare of Members. Each such local or self-governing unit in its organizations and activities should give full recognition to the fact that the majority of the membership necessarily consists of men not yet enjoying complete or independent professional status, but who in large part have had a college or technical training, and who in time may become professional engineers in the full sense of the word. Because of this diverse character of members, the activities of the local society, while maintaining high professional standards, should be so planned as to meet the needs of the young men as well as the older and be directed toward the welfare of all classes of its members and through them of the public.

5. Ethics. Each local engineering society should adopt and frequently make application of a code of ethics prepared in accord with the standards established by the national organizations or approved by other professional bodies. It is recognized that while it is impossible to prevent all violation of such a code, yet eternal vigilance is the price of maintenance of high standards. The enforcement of such a code is essential to the well being of the community at large as well as for the protection of professional men from the improper competition of unskilled or unscrupulous men tending to reduce the opportunity for effective service to individuals and to the public.

6. Civic Affairs. Each engineering society should devote time and thought to local civic, state and national affairs which influence engineering progress.

7. The Public Engineer. Each local society should give especial attention to the needs of those members who are in public employment, and should recognize the high ideals and performance of the public engineer, seeing to it that he is furnished sympathetic support in his efforts in the public service.

8. Publicity. Each independent association should maintain a local system of diffusing information on engineering subjects such as may be embraced in the term publicity or of proper advertising of the profession as a whole.

9. Employment. For the benefit of the great body of engineers there is needed the development of a scientifically planned and well conducted system of employment to be operated in coöperation by all engineering associations.

10. Conferences. A conference of representatives from each engineering organization should be held at least annually, at which all matters such as those above noted and those of general interest should be discussed.

The impression which I received was that a most earnest and sincere desire exists in those responsible for these conferences, and in the men who attend as representatives of the various local and national engineering societies, to secure, *first,* greater participation of the engineering societies in public affairs as an obligation to society; *second,* a proper ambition to secure recognition for the work of the profession by the public in general, and *third,* as a means to this end, there should be a definite effort to so inform the public about engineering works that the average layman will not only understand, but be actually interested in the manner that he would read other items of news. The conference was naturally gratified to learn the movement was spreading to effect coöperation among the national societies, which was very near completion in what is known as the Engineering Council.

C. W. R.

Engineering Society Organized in Southwest

At a convention held in El Paso, Texas, on March 8, 9 and 10, the Southwestern Society of Engineers was organized with more than one hundred charter members. Membership is open to civil, mechanical, mining, electrical or chemical engineers, or architects or other persons belonging to a technical profession, who are not less than 27 years of age, and who have been in active practice in their profession for at least six years. Provision is also made for associated, honorary and affiliated members.

In sending information about this meeting, Prof. A. F. Barnes, Dean of Engineering of the New Mexico College of Agriculture and Mechanical Arts, State College, New Mexico, states that the idea of the new society occurred to several members of the faculty of the Engineering School, and that its field is to include West Texas, New Mexico and Arizona, where there is little opportunity for the engineers who are widely scattered to get acquainted. Engineers residing in the Southwest are usually unable to attend the national society's meetings, and it was thought that it would be beneficial to all if an organization were perfected by which they could come together and exchange views on subjects of common interest. It is estimated that there are about from 800 to 1000 engineers available for membership.

National Employment Managers' Association

A conference of the National Employment Managers' Association was held at the University of Pennsylvania on April 2 and 3, under the auspices of Employment Managers' Associations of various cities, and several other organizations, local and national. The first day was devoted to a discussion of The Labor Turnover in Industry, with a banquet in the evening, at which there were miscellaneous addresses. On the second day, the subjects were the Selection of Employees and Termination of Employment: and Following Up After Hiring, the latter including a discussion of service work, mutual aid associations, etc. A National Employment Managers' Committee was formed to act as a clearing house among the local associations and to attend to such national affairs of the Society as may come up. There were approximately five hundred in attendance, from sections as far away as California, Georgia and Ontario, Canada. About fifty came from New England and fifteen from Chicago. The proceedings of the conference will be published. The Secretary is Prof. Joseph H. Willits, Wharton School, University of Pennsylvania.

Technical Textile Conference

The second Annual Conference of those interested in the consideration of problems relating to the testing and general technology of textiles and the closely allied materials, cordage, thread, and felt, is to be held at the Bureau of Standards, Washington, D. C., on May 21, and to continue for one to three days as required. Attendance is free to all persons interested. The meeting may consider the advisability of forming a permanent society for the promotion of research. A long list of topics for discussion is appended to the announcement of the conference. One of the subjects mentioned, namely, the determination of the effectiveness of textiles in resisting heat transmission, is of particularly timely interest. The value of an army blanket lies in keeping the soldier under it warm: that is, in the effectiveness of the blanket as a heat insulator. The development of a proper method for determining this quality in textiles would give the War Department a really scientific and reliable method for drawing up specifications for army blankets.

Medals for Safety Museum

The American Museum of Safety announces the following awards of the medals of the Museum for 1917:

The E. H. Harriman Memorial Medals, awarded annually to the American steam railroad most successful during the preceding year in protecting the lives and health of its employes and the public: The gold medal to the Alabama Great Southern Railway, Cincinnati, O., whose report for 1916 shows a remarkable record. Not a passenger was killed; no employes were killed in train accidents; and with more than 2000 industrial workers, none was killed and only two were injured. From minutes of meetings of employes submitted as part of the record, a wholesome stimulation of interest was evident in the direction of accident prevention and the promotion of good health. A silver replica was given to the Illinois Division of the Illinois Central Railway; and a bronze replica

to Mr. James A. McCrea, general manager of the Long Island Railroad Company, for his safety publicity campaign familiar alike to those who motor on Long Island and those who use the trains.

The Anthony N. Brady Memorial Medals, awarded for safety and health to American electric railways. The gold medal and replicas were all awarded to the Connecticut Company or its officers, New Haven, Conn.

The Scientific American Gold Medal, awarded for the most efficient safety device invented within a certain number of years and exhibited in the Museum: To the Pullman Company, Chicago, Ill.

The Travelers Insurance Gold Medal, awarded to the American employer who has achieved greatly in protecting the lives and limbs of workmen: To the Commonwealth Steel Company, St. Louis, Mo.

The Louis Livingston Seaman Gold Medal, awarded for progress and achievement in the promotion of hygiene and mitigation of occupational diseases: To the Julius King Optical Company, New York.

Talk on Aeronautics at Buffalo

Charles H. Manly, consulting engineer of the Curtiss Aeroplane Company, addressed the Engineering Society of Buffalo on April 19 on aeroplanes for the destruction of submarines. He said that in the immediate future there will be very important developments in flying boats. The answer to the submarine will be the flying boat large enough to carry a gun of sufficient caliber to sink a submarine when the latter is submerged or when nothing but its periscope is showing. Such a flying boat might also readily be equipped with torpedoes and tubes for launching them so that it could fight the submarine with its weapons, or it could be used against commerce raiders.

The largest flying machines will be of the marine type, and machines several times the size of any so far made will be seen eventually. The Curtiss flying whale now being tested by the United States Navy in Florida, has an upper wing spread of more than 90 ft.; is driven by two 200-hp. motors and has a boat 46 ft. long, weighing with fuel and pilot more than 5,500 pounds.

Several manufacturers of gears met at Lakewood, N. J., early in April and formed the American Gear Manufacturers' Association, the objects of which are stated to be to promote the interests of the gear industry by the standardization of gear designs, manufacture and application. The president is F. W. Sinram, Van Dorn & Dutton Co., Cleveland, O..

The Society of Terminal Engineers has been recently incorporated under the laws of the State of New York with headquarters in New York City, to promote the study of terminal engineering and mechanical freight handling as a specialty. A partial organization so far effected has H. McL. Harding for president, and J. Leonard as secretary. The office of the secretary is at 133 Broadway, New York City.

With its April issue, *International Marine Engineering* completed its second decade of usefulness as a technical journal of high character devoted to the interests of the shipbuilding industry. The double number marking the anniversary contained special articles dealing with recent progress and developments in the field of marine engineering.

This Month's Abstracts

One of the most significant features of modern engineering is the use of new materials of construction. The nineteenth century will always be known as the one in which was introduced commercially the greatest material of construction which most profoundly affected the life of mankind—that is, steel.

To the present century, however, belongs the honor of the consummation of the art of production of composite alloys, both ferrous and non-ferrous, with definite and often strikingly new properties, and the art of modifying the properties of carbon steel by heat treatment. Among the abstracts in this issue will be found data on developments in both of these latter directions.

H. W. Gillette and E. L. Mack, in a paper to be read at the Kansas City meeting of the American Chemical Society, discuss the so-called ferro-uranium, of interest because of great claims made for uranium steel as a tool steel. The data collected by the authors do not appear to support these claims.

Another article, by James Scott, Mem.Am.Soc.M.E., discusses the use of boron as a purifying and deoxidizing constituent of copper, aluminum, and copper-nickel alloys. This is of interest because, as appears from the work of the present writer, and especially the papers read before the various societies by Dr. Weintraub of the General Electric Company, boron imparts very remarkable physical and electrical properties to copper (compare paper read by Dr. Weintraub before the International Engineering Congress, 1915, vol. 9).

In the field of heat treatment of steel an interesting tendency is disclosed in the article by W. H. Phillips discussing the application of methods of heat treatment as perfected for automobile gears to the case of gear trains in rolling mills. This article suggests a promising subject for laboratory research, namely, the effect of dynamic blows on spur gearing when running at high speed and transmitting heavy loads.

The attention of those interested in locomotive design is called to the important tests of Atlantic type locomotives recently carried out at the testing plant at Altoona of the Pennsylvania Railroad Company.

Gardner T. Voorhees, Mem.Am.Soc.M.E., in *Ice and Refrigeration,* presents the results of a highly interesting investigation into the still somewhat unexplored region of the latent heat of ammonia. Substantially the work is based on experimental data previously published by Prof. J. E. Denton in the *Trans.Am.Soc.M.E.,* but the writer develops a new method for determining the value of the latent heat of ammonia and presents a series of interesting considerations on this subject. The matter of heat losses in the expansion valve is treated in this article with great thoroughness.

How much may be gained by a closer insight into comparatively simple phenomena is well illustrated by F. R. Low, Mem.Am.Soc.M.E., on Energy Stored in a Boiler Under Pressure, in *Power.* The writer discusses essentially the question whether the work done in forcing back the environment when water changes to steam should be included in calculating the energy released by a pound of water under certain assumed conditions. The interest of the article lies, however, in the fact that it brings out with great clearness the proper way of treating the various constituents forming the total energy released when a boiler under pressure explodes.

Attention is called to the advance notices of technologic papers on Glasses for Protection of the Eyes from Injurious Radiations in the Section *Safety Engineering,* and on Temperature Measurements in Bessemer and Open-Hearth Practice in the Section *Measurements,* published by courtesy of the U. S. Bureau of Standards.

REVIEW OF ENGINEERING PERIODICALS

SUBJECTS OF THIS MONTH'S ABSTRACTS

Air Machinery

Blast-Furnace and Steel-Mill Power Plants, Richard H Rice and Sanford A. Moss

Discussion of the most economical type of plant when all costs are included. A comparison of turbo-blowers for blowing and turbo-generators for generating electric power for steel mills from surplus gas on one side, with a plant using gas directly in gas-engine-driven blowers and generators on the other hand. Complete tabulations of the cost of operation of each plant for four blast furnaces are given; compare Table 1.

The writer discusses the centrifugal-compressor blast not only from the point of view of cost, but also from that of effect on the furnace, and calls particular attention to its steadiness and easy controllability.

As regards the value of accurate control of the rate of air flow in the case of a blast-furnace compressor, the writer quotes the following experience. The measuring device which was relied upon to determine the rate at which the blast was being blown was so located that the indications were inaccurate. This resulted in an inaccurate adjustment of the machine. After a considerable period of operation under these conditions the measuring device was so relocated as to make it more accurate. As a result the quantity of dust is said to have decreased to normal, and the output of the furnace increased.

The writer describes in this connection the governor used on blast-furnaces blowers built by the General Electric Company. A recent improvement of this governor consists of a means of adjusting the index on the sliding weight to compensate so that the weight can readily be set to take account of the variations in atmospheric conditions. This device is called a volume director.

In the early days of our experience with centrifugal compressors on blast furnaces there used to occur the so-called "surging," which appeared when the machines were operated at considerably less rates of blowing than those for which they were designed, or when excessive pressures were met with as in case of tightening up of the furnace. This "surging" consists of an alternate forward and backward flow of air with the compressor, and is the result of improper functioning of the discharge vanes owing to the variation of blowing conditions from those for which the vanes were designed. The steps which have been taken to eliminate this "surging" are reasonable proportioning of the machine to the requirements of the furnace, and provision of a by-pass with an automatic valve which in conditions which would ordinarily permit "surging" leads back into the inlet a small quantity of air.

The major part of the paper is devoted to a discussion of comparative costs of the two types of plant, turbine- and gas-engine-driven. (*Proceedings of the Engineers' Society of Western Pennsylvania*, vol. 33, no. 2, March 1917, pp. 81-130, 6 figs. c[illegible]

TABLE 1 COMPARATIVE COSTS FOR TYPICAL FOUR-FURNACE PLANTS

	Gas Engine.	Steam Turbine.
First Costs		
Primary Washers	$131,250	$131,250
Secondary Washing Station	300,000	......
Gas Pipe from Boiler House	212,500	......
Boiler and Piping	167,500	609,200
Boiler House	41,250	123,750
Electric Station Apparatus	3,250,000	745,600
Electric Station House	250,000	69,200
Blowers, etc.	1,812,500	726,416
Blowing Station House	237,500	69,200
Pumping Station, Standpipe, Conduits	787,500	293,484
	$7,190,000	$2,768,100
Charges, Dollars per Year		
Primary Gas Washers	$2,100	$2,100
Secondary Gas Washers	42,000	......
Boilers	12,000	52,750
Electric Station	90,000	68,250
Blowing Station	49,500	42,000
Pumping Station	6,000	4,000
Running Charges, Total	$201,600	$169,100
Fixed Charges at 13 per cent	934,500	359,800
Coal	21,652	78,352
Total Charges	$1,157,752	$607,252

Chisels

Chipping Defects from Steel Billets

Chipping is a costly practice, and unless properly handled may become excessively so.

Unskilled labor of the cheapest type obtainable proves to be the best suited for this work; in fact, no other can be had, as the job of chipping is extremely unpleasant, because of the constant jar of the hammer and the stooped-over position necessitated by the work. Under present conditions 25 cents or more per hour is an average price paid to chippers working ten hours per day, and unless the chippers are kept working as constantly as possible, the costs mount up incredibly.

The job is a hard one and chippers will avail themselves of the slightest excuse to stop work. An investigation recently carried out in a large steel plant in the Central West showed that most of the time lost arises from chisel breakage, or, in general, defective chisels.

This investigation resulted in the development of certain methods which are said to have reduced the cost of the operation. Where billets require chipping a thorough inspection must cull out the defective ones.

As regards the chipping hammers, Fig. 1 shows an improved type of two-piece nozzle used for holding the conical-shank chisels found more satisfactory than the type formerly used. The air consumption per hammer is 19 cu. ft. per min.

In order to keep air hammers in good working condition they must be properly cleaned and oiled at frequent intervals. For lubrication a small amount of clean light machine oil should be poured into the inlet of the handle, and when the tool is being constantly used, this should be done every two or three hours.

The matter of chisels is of very great importance. A typical steel for chipping chisels at one plant analyzed as follows: carbon 0.70 to 0.90 per cent, sulphur 0.035 per cent, phosphorus 0.015 per cent, and manganese 0.20 per cent.

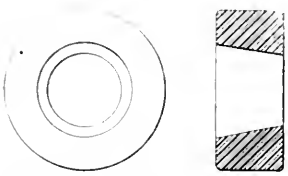


Fig. 1 New 2-Piece Nozzle For Air Hammer

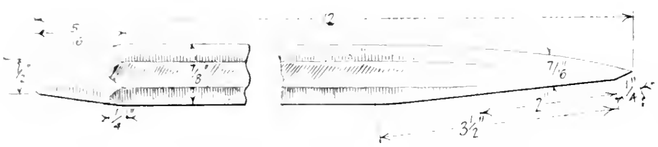

Fig. 2 Standard Half-Round Chisel

Each chipper needs from six to twelve chisels on hand at all times. Where chisels are used in large quantities it is found economical to have shanks machined outside at contract prices. Forging, shaping, and heat treatment are best performed in the plant, because of the necessity for having a repair man on chisels most of the time. Chipping chisels are subject to severe service requirements and rough treatment. Hence the steel should be put in the best possible condition. No rule-of-thumb heat treatment is effective, and the results of the tests conducted demonstrate the superiority of chisels treated under pyrometric control.

Experience has shown that straight 0.70 to 0.90 per cent carbon steel is well adapted for chipping chisels. A number of experiments were carried out at the plant referred to in this article for the purpose of standardizing the heat treatment of chisels. The following treatment was finally devised: Chisels of 0.80 per cent carbon steel were heated to 735 deg. cent., or just through the critical range, in a gas-fired muffle furnace having uniform temperature. Fifty chisels were charged at once and allowed to soak until a pyrometer rod in the middle of the pile showed 735 deg. cent. The assumption was that the entire pile of chisels had attained at least that temperature. Readings with the pyrometer at different places in the pile showed this assumption to be sufficiently accurate for practical purposes. When up to heat, the chisels were quenched by immersing the point about 1.5 in. in water. The strains induced by this drastic quenching were relieved and the resultant hardness mitigated somewhat by drawing the chisels at 250 deg. cent. in a bath of high-flash quenching oil. The drawing temperature was discovered by trial of the chisels. Lead baths for heating the chisels prior to quenching are preferable.

A great deal of trouble with chisels is due to improper grinding methods. The steel is injured by "drawing the temper," which really means that sorbite and pearlite are formed as the critical range is approached, as well as by checking and service cracks. For hard carbon chisels grinding wheels of fine grain are recommended, and the pressure during grinding should be light.

As regards the shape of the chisels, a half-round chisel proved to be the most suitable for the purpose. The one shown in Fig. 2 was adopted as standard. (*The Iron Trade Review*, vol. 60, no. 12, March 22, 1917, pp. 682-684, 4 figs., *p*)

Engineering Materials

Ferro-Uranium, H. W. Gillet and E. L. Mack

General discussion of uranium-iron alloys, their production and properties.

According to the information collected by the author the use of uranium in steel dates back at least as far as 1897. Among other things Escard repeated nearly ten years ago a report that Krupp used uranium steel in armor plate, and there have been various rumors that Germany is using uranium-steel liners in big guns in the present war.

In the United States commercial use of uranium steel is quite recent. According to a statement by R. M. Kenney in the "Mineral Industry" (1915), a high-speed steel showing excellent cutting qualities contained C, 0.078 per cent; Mn, none; Si, 0.16 per cent; P, 0.02 per cent; tungsten, 8.15 per cent; Cr, 3.62 per cent; vanadium, 1.18 per cent; and uranium, 1.02 per cent.

While uranium steel has been widely advertised as the last word in high-speed tool steel, the reports of Hoffman and Johnson were not so favorable, the former stating that a uranium steel with 5 per cent tungsten and 3 to 4 per cent Cr made a very good tool and did good work for, say, two grindings. After that it did not hold its efficiency and had to be rehardened. Johnson stated that a 40-point carbon steel with 0.3 per cent uranium was disappointing, being red-short at ordinary forging heat and altogether uninteresting from a practical point of view. Therefore, in the opinion of present writers, all that can be said now is that uranium deserves a careful trial, both in tool steel and in ordnance, though the former is probably the more promising field.

As regards the composition of the so-called uranium steels, Johnson states that he has encountered ferro-uranium containing 15 to 20 per cent aluminum and that vanadium was always present from 2 or 3 per cent to 28 per cent; he stated also that one ferro-uranium analyzed by him contained 15 per cent silicon.

The price of American ferro-uranium in February [and April—Ed.], 1917, was $7.50 per lb. of uranium content. Partly on account of the price, experiments on uranium steels seem to have been confined to those with the maximum of

about 1 per cent uranium. It would be desirable to try it out with a percentage of 10 to 12 per cent, similar to that of tungsten in tungsten tool steels, even though such a steel may not be commercial.

The article further discusses in detail the method of production of uranium steels, in particular in an experimental furnace. (Paper to be read at the Kansas City Meeting of the *American Chemical Society*, abstracted through the *Journal of Industrial and Engineering Chemistry*, vol 9, no. 4, April 1917, pp. 343-347, *ge*)

INFLUENCE OF GASES IN CAST METAL, J. E. Fletcher

Practically the only thing known about the constituency of molten cast iron and steel is that they must contain in solution iron, carbon, silicon, manganese, phosphorus, and sulphur, but it is not exactly known how these metals and metalloids occur when in the liquid state. The iron-carbon alloys solidify first and are followed by others in ordered succession. In cast iron, for example, there is a constituent which is a metallic mixture of iron carbide and iron known as the eutectic containing 4.3 per cent of carbon, and also another similar constituent containing 0.9 per cent of carbon and known as the eutectoid pearlite.

The author has made many experiments in the way of quenching various carbon-iron and other alloys from the molten state and believes that there are definite structures even in the liquid metal itself. Further, he considers it as certain that the 4.3 per cent carbon eutectic can be superheated to 1500 deg. cent., which is the melting point of iron, and on being quenched will still reveal under the microscope a characteristic stratified honeycomb structure. The silico-ferrite crystallites under such circumstances are small, but of the characteristic fir-tree or dendritic structure.

The gases are imprisoned or dissolved in all molten metals and in cast iron and other eutectic-containing metals or alloys. These gases are very probably the formative or directive element in the growth of a honeycomb-like formation of the primary eutectic. The flow-line structure always having a direction towards the upper and hotter portions of the freezing mass of a eutectic ingot, gives the impression of fine gas streams set in motion by conventional forces, just as the streams of steam bubbles are given conventional flow in a boiler. It may be that the primary gas streams in flowing through the semi-liquid carbide of iron plate-like crystals make the paths through which the more or less carburized ferrite enters and freezes, such freezing action being immediately followed by that of the carbide.

The structure of a cast iron in the opinion of the writer must have some relation to the primary structure it received in the blast furnace. While the ores are being reduced the iron oxides are attacked by the carbon monoxide gas which is both the principal reducing agent and the chief carburization medium. This produces the spongy porous nature of the reduced iron and may be called the first stage of the gas-absorbing tendency of the iron. The hydrogen which is also imprisoned by this action comes from the moisture evaporated from the blast ores, flux and fuel.

In the study of the gas influence the principal use of the microscope is in tracing the difference in crystalline structure between the outer rapidly cooled and the inner slowly cooled zones of a casting. If the cooling curves are taken simultaneously at each of these zones, in many cases the difference in the freezing behavior with its action of the phenomena of shrinkage and contraction may be observed.

Just previous to freezing of cast iron or steel the liquid metal may be conceived to consist of an agglomeration of liquid particles or crystals of various constituents of iron and manganese. The crystallites of partly carbonized iron first separate out and freeze at the molten surface and at right angles to it. Almost immediately afterwards the spongy of iron freezes around the iron crystallites and these crystallites, as they freeze, eject their occluded gases into the mother liquor or eutectic. As the iron or silico-iron crystallites enlarge and grow laterally the gases are driven inwards. The volume of any such partially frozen portion of the metal is as follows: Primary crystals A + mother liquor B + ejected gases C. As A increases, B decreases, while C simultaneously decreases. In cast iron the mother liquor B contains the segregates, slags, oxide and sulphide particles, together with the graphite flakes

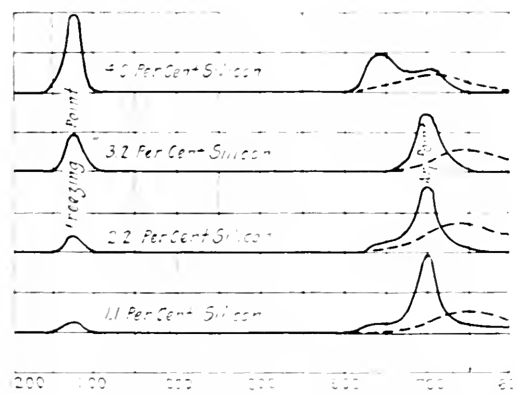

FIG. 3 DILATION OF CAST IRONS (DOTTED LINES 2% MN)

which escape with the gases into the hot fluid portions, which, when frozen, contain the highest percentages of these impurities. The gases thus liberated travel to the hot zones in the castings which are the last to freeze, and if there is no way for them to escape produce gas cavities or pipes.

The writer raises the question whether the phenomenon of shrinkage is connected with the volume of occluded gases, or rather with that of gases escaping during the freezing of iron and steel, and finds many evidences in favor of the latter conclusion.

Such is the case of a mild-steel block which was cast from a ladle of well-melted steel held in the ladle accidentally until close on the point of setting or congealing. The nozzle gave out and allowed scarcely any steel to rise in the casting head or riser. When cold the block was found to have contracted less than 1/16 in. per ft. The metal when planed revealed no pipe or cavity and was free from blowholes, while the weight of the casting indicated soundness. This case points to the fact that the gases escape freely during the slow rising of the steel in the mold, and that the occluded gases finally remaining in the metal mass were in a fine state of entanglement between the crystals uniformly throughout the mass. A similar casting made in the same heat from a more fluid steel piped deeply in the rising head and contracted normally at the rate of 0.2 in. per ft.

Whenever castings are made in chilled molds there must be shrinkage or contraction. Under such circumstances rapid freezing has a tendency to form small primary crystals which become quickly interlocked, imprisoning small gas bubbles. The cooling of the mass causes a shrinkage of the gas bubbles and it has been concluded that each gas globule occupies much less volume at 60 deg. fahr. than at 2000 deg. fahr.

From here the author proceeds to the discussion of the volumetric change during the freezing and later cooling of iron, as dependent on the analysis of the metal.

He bases his discussion mainly on the work of Professor Turner in this country.

Of interest is the part of the discussion referring to what happens at the point of recalescence. At that point there is another expansion (the primary expansion occurs at the moment of freezing), generally connected, as Professor Turner suggests, with the liberation of more free carbon, or temper carbon, and probably with the further increase in the volume of the gases as a result of the heat evolution which then takes place.

Baker in his experiments on the quantity of gases drawn off from iron and steel heated in a vacuum, decided that the greatest quantity is ejected at the recalescence point, thus confirming the work of earlier investigators. More recently Charpy concluded that the expansion or dilation of carbon-iron-silicon alloys was increased at the freezing point as the silicon content rose, while the expansion at the recalescence point is diminished, as is shown by the curves in Fig. 3.

This conclusion confirms experiments made by the author on cast irons with varying silicon contents, in which it was found that manganese and silicon together intensified such action. Generally speaking, white irons shrink most. The more highly silicious irons shrink last. But it would seem that whenever the iron carbide in either the primary crystals or in the eutectic is retained, as is the case when manganese or chromium is present, the speed of freezing is increased, and the gases liberated are driven rapidly into the more fluid portion of the metal mass, where there is a tendency to form shrink cavities. In low-silicon irons, free from phosphorus, high manganese generally produces such results, especially if the casting temperature is low. The presence of phosphorus is an aid to gas escape into the hot interior of a cooling casting.

The question of hot-casting is allied with the problem of shrinkage and of gas exit. Generally speaking, when the metal is cast hot there is a better distribution of the gases which remain in the cold metal and less risk of blowholes and cavities.

Hot-casting is especially important in the case of pure irons of hematite and cold-blast character low in total carbon, phosphorus and silicon. Such iron cools and shrinks rapidly, because its primary crystals freeze at a high temperature, and the mother liquor being purely eutectic also freezes rapidly.

The author calls attention to the fact that the importance of taking into consideration the influence of gases in the foundry problem can scarcely be underestimated. The major portion of foundry troubles are associated to a certain degree with the question of occluded gases. (Paper presented at a meeting on November 27, 1916, of the Birmingham Branch of the *British Foundrymen's Association*, abstracted through *The Iron Trade Review*, vol. 60, no. 11, March 15, 1917, pp. 617-621, 9 figs., *et*)

Boronized Metals, James Scott

Boron, which has an atomic weight of 10.9, is an element which, like carbon, is allotropic. It has a strong affinity for oxygen and may, therefore, be used as a deoxidizer. Boric acid (B_2O_3) has a remarkable property that when dry it can be heated to a high temperature without vaporizing, but when dissolved in water it readily passes away in the steam produced by boiling. From this it appears that its ability to prevent the development of blowholes is due to this refractoriness. It not only fails to generate cavities itself, but in some way attracts fumes which might otherwise get imprisoned in solidified metal.

The author microscopically examined the three more important boron alloys, namely, aluminum, copper, and copper-nickel.

The superficial texture of these alloys is shown in the original article in magnified microphotographs.

The form in which boron is now used for the purification of metals is as a fluoride. (*The Metal Industry*, vol. 15, no. 3, March 1917, pp. 115-116, 3 figs., *de*)

Foundry

The American Foundry in Time of War, Edgar Allen Custer, Jr.

The writer discusses in a general manner the conditions which American foundries had to meet when the European demand for munitions arose in this country, and the further conditions for which they should be ready with the United States itself facing the problem of war.

The production of cast-iron or semi-steel shells presents difficulties that heretofore few, if any, foundries have been called upon to meet. The range of physical qualities is limited to almost one precise point that will give the proper fragmentation, and it is essential to obtain and maintain this point. Too great a resistance to the bursting effect not only reduces the number of fragments, but necessarily reduces the destructive capacity of the shell, since too great a proportion of the explosive effort is needed to effect the bursting; on the other hand, insufficient resistance results in excessive fragmentation in which the pieces are so small that they are not capable of serious damage.

In addition to this, a sound casting is absolutely essential, not only because unsoundness tends to interfere with proper markmanship, but still more because of the possibility of a weak spot giving way under impact in the gun which may result in tearing the gun to pieces.

These strenuous conditions call for a most exact method of procedure. The chemical analysis of the heats must be not approximate, but exact, and it is significant that 75 per cent of rejections in French factories, while endeavoring to produce satisfactory semi-steel shells, could be traced directly to faulty analysis of the mixtures. To successfully produce semi-steel shells designed for active service the foundrymen cannot rely on approximations or the analysis of the irons guaranteed by a salesman, but must use the services of a chemist.

The next point of importance is the management of the cupola. The method of laying, lighting, and burning up a fire should absolutely eliminate the possibility of a poor start, for such a start may spoil the whole heat. Thus a poor start may mean that quite a proportion of the first metal charged is melted at a temperature below that necessary to produce satisfactory semi-steel. This may result in as much as 20 to 30 per cent of the heat being unfit for use.

The work of weighing and charging must be executed carefully and not left to the discretion of the laborer on the platform. Too often the given quantity is measured as average pigs, or so many buckets or forks of coke, and generally some more for good measure. Such a method of cupola operation is sufficient to set at naught any close or active work on the part of the chemist.

The melting temperature should be kept as constant as possible and at a point slightly above normal. Semi-steel like

cast iron will absorb or throw off impurities according to its melting temperature. In handling the metal it was found that the best results could be obtained by using a specially constructed receiving ladle under the spout of the cupola.

Second in importance to the chemical analysis and the means of obtaining it, comes the molding of semi-steel shells. According to one report a foundry in northern France failed to produce a single satisfactory heat until green-sand molding was abandoned. Too much attention cannot be paid to the use of the trap gate in molding with semi-steel, especially on shells. The position of the casting when poured gave considerable trouble when the French factories first started on semi-steel shells. At first it was considered necessary to pour the casting on end and to allow extra metal on the cope to collect dirt and gas holes and to provide metal for possible shrinkage, but later on the vertical form of molding was largely-discontinued, and this permitted the use of the match-plate form of machine molding and molding the shells in pairs, using a balanced core.

Among other things discussed in the article are the methods of taking samples of metal, analysis and inspection of the product. (*The Foundry*, vol. 45, no. 294/4, April 1917, pp. 127-130, *p*)

Fuels and Firing

The Permeability of Coal to Air and Gas and the Solubilities of Different Gases in Coal. J. Ivon Graham

A knowledge of the permeability of coal to air or gas is important for the comprehension of the processes of spontaneous heating in coal and the production and discharge of firedamp and blackdamp.

In experimenting on the permeability of coal to gases, difficulty was at first experienced in obtaining a gastight seal between coal and any form of connecting tubes. The method finally adopted as most satisfactory was as follows: Thin slabs were sawn off from a large lump by means of a fine hacksaw. Some of the slabs were cut in the direction of the cleavage of the coal, others at right angles to it. Pieces of glass tubing ½ in. to 1 in. in diameter were sealed on each side of the slab. To obtain an airtight seal, the following method was adopted: The end of the glass tube previously warmed in a blowpipe flame was dipped into molten bitumen, such as is used for electrical insulation purposes, and a small quantity of bitumen in an almost molten condition was thus obtained on the end of the tube. The latter was then quickly pressed against the coal slab and held rigidly until the bitumen became quite hard. Successive thin layers of seccotine were next applied around the junction and allowed to dry. A second tube was then sealed on to the opposite side of the slab in a similar fashion. It was found that by this method a practically airtight seal could be obtained, sufficiently tight to hold a vacuum for several days.

In the case of "softs" it was found almost impossible to obtain a slab free from cracks, owing to the fragile character of this coal. In cannel, cracks also developed very rapidly. The majority of the results so far obtained, therefore, deal with slabs from "hard" coal.

The article describes in detail the methods of experiment followed with various gases, and presents in tabular form a summary of results. These results are quite remarkable, as they show that, contrary to the usual supposition, solid coal is extremely airtight and lets very little air or gas through, even with a driving pressure of a whole atmosphere. Carbon dioxide passes through the slab much more slowly than hydrogen, and to a similar extent the same may be said to be true of methane.

It was thought at first that the solubility of the gases, which is very high for carbon dioxide and methane, might affect the results for the initial stages for the flow of gas through the slab. It was found, however, that this is not so.

The writer proceeds to show how the results obtained affect the explanation that the heatings and fires which often occur in the walls of main roads driven through solid coal, commonly many years after the roads have been driven. These fires are ascribed to "breaks" in the coal which let in the oxygen. These breaks appear to be just as dangerous many years after the road has been made as with a freshly made road.

The article proceeds next to the description of experiments on the solubility of gases in coal, and in particular on the solubility of methane.

It has been found among other things that there is a considerable variation in the degree of solubility of various gases and that this diminishes in every case with rise of temperature. For the less soluble gases the amount dissolved is practically directly proportional to the pressure or concentration of the gas over the coal (practically Henry's law for the aqueous solution of gases). For the more soluble gases, as carbon monoxide, methane and carbon dioxide, "the amount dissolved—concentration of gas" curves deviated somewhat from a straight line, this deviation being the more evident the greater the solubility of the gas. In fact, the amount dissolved at low concentration of gas appears to be proportionately greater than that dissolved at high concentration.

Among other things the influence of the coarseness of the dust on the solubility of the gas has been determined, as well as the solubility of gases in finely powdered shale dust (*Trans. Inst. Min. Eng.*, vol. 52, pt. 3, February 1917, pp. 338-347, *e*)

Spontaneous-Ignition Temperatures of Liquid Fuels for Internal-Combustion Engines, Harold Moore

Flash points and burning points are common tests used for both liquid fuels and lubricating oils. These properties provide a measure of the danger from fire which is encountered in the handling and storage of the fuels, but are of little use as an indication of the behavior of a fuel in an internal-combustion engine. Such an indication, however, is given by the temperature of spontaneous ignition, which is the temperature at which a substance surrounded by oxygen or air at the same temperature will burst into flame without an application of any spark or other local high temperature.

The paper describes the experimental apparatus by which the spontaneous-ignition temperature was determined, and Table 2 gives the results obtained.

In a Diesel engine firing depends upon spontaneous ignition of the fuel immediately after it enters the cylinder. It is, therefore, necessary to employ high compression pressures in order to obtain a temperature high enough to insure the spontaneous combustion of the charge, but provided the temperature is obtained, it is advisable to keep the compression pressure low. Hence the temperature at which the fuel will ignite spontaneously is of fundamental importance. By means of the formula

$$T_2 = T_1\left(\frac{P_2}{P_1}\right)^{\frac{n-1}{n}}$$

it is possible to calculate approximately the temperature to correspond to any given compression. In this formula T_2 and

T_2 and T_1 are respectively final and initial absolute temperatures. P_2 and P_1 are respectively final and initial pressures, and n is a constant approximately equal to 1.35.

As an example of the influence of the ignition temperature of a liquid fuel the case of alcohol may be taken. It has been found in practice that alcohol, though much lower than gasoline in calorific power, when run in an engine can be made to yield approximately the same power per unit volume as gasoline.

TABLE 2 TEMPERATURE OF SPONTANEOUS IGNITION

Description	Sp. gr.	Spontaneous ignition temperature, deg. cent.		Difference, deg. cent.

The net calorific power of gasoline is about 10,450 calories per gram, or 7315 cal. per cc. The net calorific power of commercial alcohol is about 5420 calories per gram, or 4440 cal. per cc. If both be burnt in an engine with the normal compression (i. e., compression adjusted to suit gasoline), the consumptions per b.hp-hr. will be approximately in inverse proportion to the calorific powers of the fuels, and over 1½ gal. of alcohol will be required to do the same work that 1 gal. of gasoline will. Now, the spontaneous-ignition temperature of gasoline (in oxygen) is about 272 deg. cent., while that of commercial alcohol is 395 deg. cent.; therefore alcohol will withstand a much higher compression.

The compression pressure of a gasoline engine tuned to run on gasoline is approximately 90 lb. per sq. in., but with alcohol this pressure may be raised to 200 lb. per sq. in., and by this means the overall thermal efficiency of the engine is raised from about 22 per cent to 35 per cent, when it is found that the volumetric consumption of alcohol per brake horsepower-hour is approximately the same as that of gasoline. Thus though gasoline possesses 65 per cent greater calorific power than alcohol per unit volume, the advantages of this high heat value are entirely lost on account of its low ignition point. The ignition temperature is of general interest to chemists, as it is a measure of the relative stability of the bodies towards heat. The accompanying table shows the spontaneous-ignition temperatures of several fuels which have been determined with the instrument described in the original article.

From general observations the author has concluded that:

1 Compounds containing simple molecules have higher ignition points than similar compounds containing more complex molecules. This rule applies to all types of compounds.

2 Ignition points of aromatic compounds are much higher than those of alipathic compounds.

3 Saturated hydrocarbons have lower ignition points than the corresponding saturated hydrocarbons.

4 Ignition points observed in air are higher than those observed in oxygen. This difference for petroleum products is generally 100 to 200 deg. cent. (*Journal of the Society of Chemical Industry*, vol. 36, no. 3, February 15, 1917, pp. 109-112, 2 figs. *eA*)

Internal-Combustion Engineering

THE USE OF KEROSENE IN GASOLINE ENGINES INSTALLED IN THE FORTIFICATIONS OF THE UNITED STATES, Capt. Charles O. Schudt and First Lieut. John W. Wallis, Coast Artillery Corps, U. S. A.

The writers do not believe in the possibility of the use of alcohol in such engines, and therefore limited their tests to kerosene only. These tests were carried out in the laboratory of the Coast Artillery School, and were made on the following engines:

Lathrop single-cylinder, two-cycle marine engine
Ferro single-cylinder, two-cycle, three-port portable engine
Engine attached to 5-kw. generating set; this is a four-cylinder, four-cycle stationary engine
Similar but larger engine attached to 25-kw. generating set.

The test with the Lathrop marine engine gave rather perplexing results. The engine had been operated many times previous on gasoline, using the Prony-brake load at a speed

of about 380 r.p.m. When the fuel was changed to kerosene the operation was not satisfactory.

The governor was then adjusted to give a speed of 525 r.p.m. without any change in the needle valve, or without intake spring when a load of 33 lb. at a radius of 24 in. was registered at the brake. The fuel was then changed to kerosene while the engine was running, and the speed immediately went up to 550 r.p.m., while the load on the brake arm remained at 33 lb. With the same adjustment, the engine, for a considerable time, carried a load of 40 lb. on the brake arm.

In subsequent tests after the fuel was changed to kerosene, the speed drop became erratic and the engine finally stopped. It appears, therefore, that this engine could be operated on kerosene only by very skilled operators.

It is probable that the principal reason for the failure of this engine to operate more satisfactorily is that it has an excessive crankcase clearance, resulting in low crankcase compression and permitting the fuel to separate from the air and settle while the mixture is in the crankcase. That the fuel immediately separates from the air is proven by the fact that it accumulates very rapidly in liquid form in the crankcase.

In the case of the four-cylinder, four-cycle stationary engine attached to the 5-kw. generator set, it was found that the operation of kerosene was quite successful, the behavior of the engine not being materially different from its behavior when operated on gasoline. Apparently, the only necessary change in the adjustments of the engine when the fuel was changed to kerosene was approximately to double the opening of the needle valve.

A supplementary test was run on a two-cylinder, four-cycle Standard marine engine of old design with a long, exposed intake pipe. Notwithstanding this latter feature, its operation on kerosene was entirely satisfactory. In fact, the change to kerosene fuel (the needle-valve opening was increased 50 per cent) was accompanied by a material increase in speed and brake horsepower. To determine whether the engine would "idle" satisfactorily on kerosene, it was operated for fifteen minutes without compression released and spark fully retarded. At the end of this time the load was thrown on, but one cylinder missed, and the engine would not come up to speed until a little gasoline was squirted into the air intake. This gasoline caused the missing cylinder to resume firing immediately, and the engine came up to speed. The exhaust smoke was fairly clear, indicating that the combustion was good, and consequently little probability of carbonization troubles.

From the limited tests conducted, it is believed entirely practicable for the enlisted specialist now in charge of these engines to operate them without very much difficulty.

One of the important things encountered in the tests was the mechanical inaccuracy of the valve timing. The valves in these tests were timed in the manner prescribed, and the setting was then checked on the flywheel. The angle past center at which the exhaust valves opened varied 9 deg. and the intake valves varied 7 deg. It is true that at this time the piston has very little motion, but this error in the cams causes trouble with kerosene fuel.

At no time was there trouble from knocking due to preignition. Curiously, knocking was accompanied by the best combustion: in other words, when all or most of the cylinders were knocking the exhaust was nearly clear. Knocking could be increased by shutting the needle valve. The influence of velocity of flame propagation is also discussed in detail. (*Journal of the United States Artillery,* vol. 47, no. 1, January-February 1917, pp. 24-35, *e*)

Machine Parts

PISTON DESIGN WITH SPECIAL REFERENCE TO ALUMINUM PISTONS, Harry R. Ricardo

General discussion of design of pistons for internal combustion engines of high output, and description of a "slipper" type piston.

The author establishes the general conditions with which a piston of a high-speed internal-combustion engine must comply, and calls attention to the fact that piston friction depends almost wholly on the viscosity of the oil, proved by the variation it undergoes with difference of temperature of cylinder walls. He reproduces a set of three curves of mechanical losses in a four-cylinder Daimler engine that was tested by Professor Hopkinson at Cambridge University.

In this engine piston friction at the higher speeds formed nearly 80 per cent of the total mechanical loss, and its susceptibility to changes of temperature is clearly shown. In another test recently made by the writer on a single-cylinder experimental engine, it was found that the mean pressure required to overcome piston friction varied from 18 lb. per sq. in. when the cylinder was quite cold to only 6 lb. per sq. in. when the jacket water was boiling.

The assumption that the friction loss in the countershaft and crankpin bearings is greater than that of the piston has been disproved by numerous experiments; the explanation of the fact that it is actually very much less appears to be that, although the same oil is used in both cases, the piston lubricant is largely contaminated by partially carbonized oil and its viscosity enormously increased in consequence. The carbonizing and thickening of the piston lubricant is mainly (but not entirely) due to the leakage of burned gases past the piston rings. In some cases this difficulty has been partly obviated by providing immediately below the lowest piston rings a recess having a number of holes drilled through it, so that any gases that succeed in passing the piston rings can escape freely into the crankcase.

As a matter of fact, a trunk piston has to perform two separate functions. The upper part of the piston is required to retain and transmit the gas pressure and distribute and dissipate the heat. Hence it should be made strong enough to withstand the pressure and thick enough to transmit the heat; also it should not bear against the cylinder walls, or receive any of the side thrust from the connecting rod. The piston rings should be relied on to keep it gastight, and since any oil which passes above the lowest piston ring will, of necessity, be carbonized, it should receive as little oil as possible, consistent with the maintenance of the piston rings and mechanical conditions of operation.

The lower portion of a trunk piston performs the duty of a crosshead and takes the side thrust from the connecting rod. Hence it should be fitted as closely to the cylinder as is consistent with the expansion and distortion that takes place, should be freely lubricated, should have as little bearing surface as is consistent with the loading and temperature, and the oil should be kept clean by allowing a free escape of any burned gases that may pass the ring.

Since the bulk of the losses is caused by the continuous shearing of oil film, it is important to reduce the surface to the lowest safe limit: while, as a rule, bearing surface is provided around the entire circumference of the piston, it is needed only around a small arc on either side of it. The bearing surface around the two sides of the piston which receive no thrust is particularly objectionable on account of

or local distortion set up by the great mass of metal in the gudgeon pin bosses and by the bending of the gudgeon pin.

The proper way is to regard the lower part of the piston as a crosshead and design it as such, that is, provide it with just sufficient bearing surface at just the right place, have it freely lubricated and safe from the passage of burned gases between its bearing surface and the cylinder walls.

It is also desirable to perforate the bearing surface with a number of large holes, for when two freely lubricated surfaces are sliding over one another the oil between them is, so to speak, rolled up and heavy hydraulic pressure set up, and this can relieve itself by escaping through these holes.

As regards the design of the gudgeon pin, the writer believes that it is preferable to use a short and stiff gudgeon supported directly from the crown of the piston and by points as near to the ends of the connecting-rod bush as possible. The necessary surface required to carry the side thrust from the connecting rod can be provided exactly where it is needed, and there only, in addition to which a short and stiff gudgeon pin can be used without necessitating long and heavy bosses.

In Fig. 4 is shown a design of piston which the writer has been using recently, and which is probably only suitable for aluminum pistons.

The particular features are that the vertical load is transmitted directly from the crown of the piston to the center of the gudgeon-pin bosses, so that a light gudgeon pin can be used without risk of bending. The horizontal thrust from the connecting rod is transmitted directly to the bearing surfaces and is distributed over them by means of two transverse ribs. Bearing surface is provided in the form of two slippers, so that the surface of oil in shear is reduced to a minimum, leaving an ample bearing surface. No load is transmitted through the side walls or past the piston-ring grooves. The surfaces of the two slippers are perforated to release the oil and the lower piston ring acts as a scraper ring; on the two sides of the piston where there is no bearing surface the scraper ring can prevent the slippage of oil almost completely, since it has to deal only with the oil adhering to the cylinder walls and not with oil under pressure. The weight of the piston is very low; for cylinder bores ranging from 3.5 to 5 in. in diameter the weight of the piston complete with gudgeon pin and piston

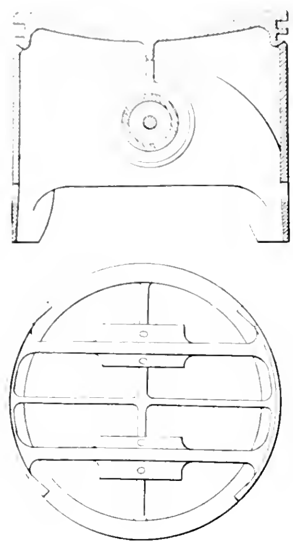

Fig. 4 Experimental Design of Aluminum Piston

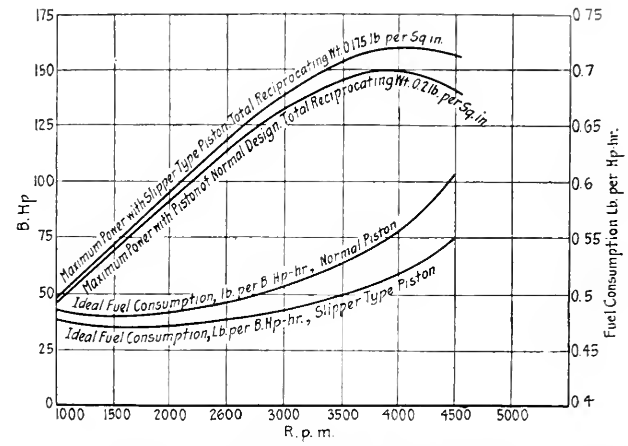

Fig. 5 Power and Fuel Consumption, Various Pistons

rings can be brought down to 0.1 lb. per sq. in. of piston area. Several pistons of this weight have been in operation for some considerable time in high-speed engines and have proved themselves to be perfectly reliable.

Fig. 5 shows a gain in power and fuel consumption to be obtained by the use of these pistons, which is ascribed to the reduction in mechanical losses. It seems probable from examination of some of the pistons which have been in operation for many months that the bearing surface might be still further reduced with perfect safety. After long runs on full load the bearing surface was found to be profusely lubricated, with the oil showing no signs of discoloration due to carbonization. Experience has also shown a reduction in the oil consumption; in one extreme case it fell from 0.06 lb. per b.hp-hour to 0.035 lb. per b.hp-hour with no other change except in the pistons. The fuel consumption dropped 4 per cent, while the brake horsepower increased by about 4 per cent. (*The Automobile Engineer,* vol. 7, no. 100, March 1917, pp. 60-63, 7 figs. *te*)

The loading on the gudgeon-pin bearing in a high-speed engine is not as severe as is generally supposed; providing the bearing is kept reasonably cold in order to maintain the viscosity of the oil, and the pin is well supported and stiff enough, it is perfectly safe to use bearing pressures vastly in excess of those now employed. Under these conditions a total projected area equal to 7 per cent of the piston area is amply sufficient for an engine running up to 3000 r.p.m., if the gudgeon pin is not more than 20 per cent of the diameter of the piston.

In the writer's opinion the best method of all is to float the gudgeon pin; that is, allow it to rotate freely in bearings, both in the piston and connecting rod, so that the rubbing velocity in each bearing is reduced to one-half. Under these circumstances the piston and the connecting-rod bearings may be reduced to 5 per cent, and that of the bearings on either side to 3 per cent with safety. The use of a floating pin has the further advantage that the difficult problem of fixing the pin and the risk of distorting both the pin and the bosses is obviated, but it must not be used unless the bosses are supported directly from the crowns of the pistons.

As regards the general design of steel pistons the writer describes two recent types, viz., the Sunbeam and the Zephyr. The aluminum piston affords a greater freedom of design, since ribs may be used with very little fear of distortion, and without adding perceptibly to the cost of manufacture.

Gearing Development Through Heat Treatment. W. H. Phillips

The author attempts to show how the development of heat treating as perfected for automobile gears may be usefully applied to the case of rolling-mill gear trains.

If by increasing the cost of gearing from 25 to 50 per cent a gear is produced that will triple the life of the untreated gear, and at the same time eliminate breakage, there can be no doubt of its economy.

The writer mainly considers carbon-steel gearing and divides its treatment into three general classes: oil treatment, case hardening, and special treatment, with particular reference to the last one.

He emphasizes the fact that poor heat treatment is worse than no treatment at all, and insists on the necessity of an exact method of procedure checked by accurate temperature-recording instruments and facilitated by a closely regulated furnace.

In addition, one or more gears in every lot of one hundred should be taken for physical test. Since, however, even this does not necessarily insure uniformity, the Brinell hardness test may be used as a check on each gear.

Extensive experimentation has shown that by slight changes in the constitution of the metal a combination can be obtained which, when subjected to a special treatment, will produce physical properties peculiarly adapted to gearing. The hardness at the surface of the steel is from three to four times that of untreated steel, and grades off slightly toward the center of the tooth until it is from two and one-half to three times as hard as untreated steel. This reduction in hardness is in a straight-line ratio, and each fiber of the steel from the surface to the center or neutral axis of the tooth—which may be slightly to one side of the geometric center—will be stressed in proportion to its ability to carry the load, so that when the tooth receives a blow or shock every fiber is carrying its share of the load.

The effect of dynamic blows on spur gearing when running at high speed and transmitting heavy loads has never been accurately ascertained, but is known to be great, often excessive, and in such service forged steel should always be used, whenever possible. (*The Blast Furnace and Steel Plant*, vol. 5, no. 4, April 1917, pp. 152-154, *gp*)

Special Cams in Aluminum Engines of Premier Car. A. L. Nelson

The writer points out the gradual degrees of clearance between the tappet and cam in the valve mechanism. The reason for this reduction of clearance is that the motor speeds have been greatly increased and the standard of quietness of valve operation has been raised.

The clearance between the end of the rocker-arm lever and the valve stem of the aluminum motor with valve-in-the-head construction and camshaft in the crankcase is a matter of particular importance. The vertical expansion of the aluminum cylinder case is about twice as great as that of cast iron. Hence with the conventional type of cam adjusted with the valve-stem clearance at the working temperature of the motor that would give satisfactorily low valve-closing and lifting velocities, all the valves would be held open when the motor was cold.

It was found by experiment that the valve-stem clearance had to be at least 0.013 in. in order that the valves would retain sufficient clearance to start a cold motor, but with this clearance and the conventional cam the valves opened and closed at such high velocities that the valve action was entirely too noisy. In addition, impact on the valve seats and on all the valve mechanism parts made the wear very appreciable.

It therefore became necessary to change the method of operating the valves by designing a new cam.

Fig. 6, upper half, shows the conventional cam contour, while Fig. 6, lower half, shows the new one. The new cam is virtually the conventional one with 0.020 in. taken off the diameter of the base circle and with a tangent drawn from a point to the new base circle. The time of opening the valve is made earlier for special reasons. Lift of the valve for the added angle is only 0.004 in., while the angular increase is 3 deg. 52 min. That is, the first part of the lift is so slow that

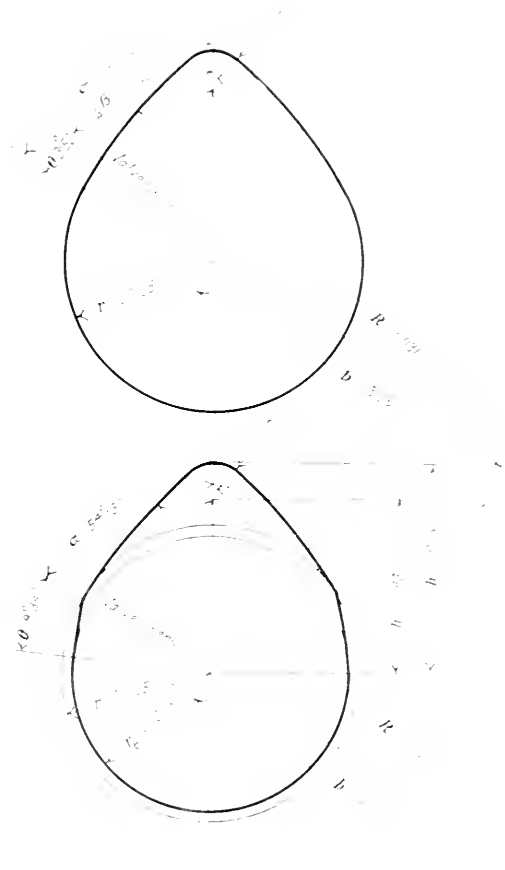

Fig. 6 Standard and Altered Cams for Automobile Engines

the valve has to be given an earlier start corresponding to the back-lash angle of the old cam.

As the valve-stem clearance increases by wear, the timing works towards the desired theoretical conventional timing and then past it instead of always away from it as in the conventional method.

An interesting feature of the design of the new cam is such an adjustment of the valve stem as to obtain an opening and closing of the valves at a cam position giving practically zero velocity at any speed.

From this the author proceeds to the mathematical analysis of the action of the new cam motion, viz., analysis of mushroom follower motion equations for the upper motion, and characteristic curves of the new cam. (*The Automobile*, vol. 36, no. 14, April 5, 1917, pp. 689-692, 6 figs, *dtm*)

Measurement and Measuring Apparatus

Temperature Measurements in Bessemer and Open Hearth Practice, George K. Burgess

The problem of temperature measurement and pyrometric control of furnace casting and ingot teeming temperature is shown, by a series of observations taken in several steel plants, to present no serious difficulties or uncertainties.

For this purpose the most satisfactory type of instrument is one of the optical pyrometers using monochromatic light and permitting observation from a distance of streams of metal.

It is shown that the necessary corrections to the observed optical pyrometer readings for emissivity of metal and oxides to give true temperatures are sufficiently well known, but there may be uncertainty in the case of liquid slags.

For streams of liquid iron or steel the most probable value of emissivity to take, with a pyrometer using red light of wave length $\lambda = 0.65\ \mu$ is $e = 0.40$, corresponding to a correction of 139 deg. for an observed temperature of 1500 deg. cent. The value of e for liquid slags is usually about 0.65, but varies with composition of the slag. A table of emissivity corrections is included in the text.

Determination of the temperature of the charge of bessemer converters is not deemed practicable by pyrometric methods.

The operation of the open-hearth furnace can be gaged by the pyrometer, it being possible to control readily the temperature of the roof and of the bath of metal and slag by observations taken through ports; and the temperature of the metal may be had at any instant, with a fair degree of exactness, by observation with the optical pyrometer of metal removed in a spoon.

The temperatures of the roof of an open-hearth furnace are shown to bear no necessary relation to that of the metal bath, which again is shown may have zones of considerable differences in temperature, depending upon the operation of the furnace.

The temperature of the roof of an open-hearth furnace, dependent upon the firing practice, may vary very rapidly and within wide limits, 1550 to 1750 deg. cent. The temperature of the open-hearth bath is usually kept between 1600 and 1670 deg. cent.

There appears to be a very remarkable degree of uniformity in casting temperature actually acquired by the melters in practice. Thus, for 10 consecutive bessemer heats the teeming temperatures of the ingots were all between 1500 and 1550 deg. cent., and a similar degree of concordance, although at slightly higher temperatures, was found in the open-hearth practice of several mills.

It is believed that a continuous, systematic following of the temperature, by the methods above outlined, for the various furnace and casting practices, on the part of steel and iron mills, would show the possibility of improvements and greater certainty of production in quality of product; also changes and the effects of variation in ingot or furnace practice could undoubtedly be carried out with greater certainty than at present appears to be the case. (*Bureau of Standards*, Technologic Paper No. 91.)

Pyrometers, Richard P. Brown

Brief historical discussion of methods of measuring high temperatures, followed by concise descriptions of modern pyrometers and methods of using them.

The writer describes in particular the use of thermoelectric pyrometers, with and without compensating boxes; the two methods of measuring the voltage produced by a thermocouple, namely, the millivoltmeter and the potentiometer methods; and finally, the use of the radiation pyrometer.

Methods of calibration of pyrometers are briefly described. The writer believes that the greatest feature in pyrometry is along the line of automatic temperature control, and calls attention to the fact that there have been already designed instruments capable of maintaining the temperature constant within 10 deg. fahr. He further suggests that the steel manufacturers, who are interested in the improvement of heat-treating methods, can be of great assistance to pyrometer manufacturers in coöperating with them to test out new devices in an endeavor to improve on present methods. (*The Iron Trade Review*, vol. 60, no. 12, March 22, 1917, pp. 671-673, *g*)

Mechanics

The Comparison of a Certain Case of the Elastic Curve with Its Approximation, R. W. Burgess

In the usual discussion of the elastic curve in elementary textbooks of physics and engineering, a certain term in the differential equation of the curve is neglected and the curve resulting from this approximation is said to be a good substitute for the real elastic curve. It is my purpose in this note to show by a comparison of one case of this approximate solution with the accurate solution, that the one is not always a satisfactory substitute for the other.

If a straight, thin rod in which I is the moment of inertia of a cross-section about a line perpendicular to the plane of bending, and E the constant of elasticity, is bent into a bow by two opposing forces each of magnitude H, acting at the ends of the rod, it is assumed, or deduced from more elementary assumptions, that the resistance to bending at any point is proportional to the curvature of the central axis at that point. The bending moment at any point is therefore proportional to the curvature; taking the central axis when unbent as the x-axis, and a perpendicular at its mid point as the y-axis, we have $Hy = EI/\rho$, that is, $\rho y = EI/H = a^2$, say, as the equation of the central axis. We can without difficulty integrate this equation, subject to the conditions $y = h$, $dy/dx = 0$ when $x = 0$. Substituting the known value of the radius of curvature in the equation $\rho y = a^2$, we obtain

$$a^2 \frac{d^2y}{dx^2} = -y\left[1 + \left(\frac{dy}{dx}\right)^2\right]^{3/2}$$

From this the author derives the common expression

$$l = \pi a\left[1 + \frac{h^2}{16a^2} + \dots\right]$$

The usual approximation is to omit from the original expression the term for the slope $(dy/dx)^2$, which is small if the bow is only slightly bent. The equation is then

$$a^2 \frac{d^2y}{dx^2} = -y$$

and the solution is $y = h \cos x/a$, which is said to be a good approximation to the solution.

Actually, however the author shows that for small deflections the error of this solution is nearly 100 per cent. He thinks therefore that the cosine curve, with h determined by a formula deduced from this equation, is not satisfactory, in any case where the length of the bow or column is one of the given physical constants. The difficulty is of course due to

the fact that deflection is of the same order of magnitude as the slope which was considered negligible.

Errors of this nature due to dropping terms from a differential equation probably exist in other physical problems; this one is unusual in that both the exact and the approximate equations can be solved in terms of known functions. (*Physical Review*, vol. 9, no 3, March 1917, pp. 193-197, *tm*)

Railroad Engineering

Pennsylvania Atlantic-Type Locomotive Tests, Andrew C. Loudon

The article describes the most recent form of Pennsylvania Atlantic-type locomotive, as well as the tests carried out at the testing plant at Altoona.

During the period of development of the Atlantic-type locomotive, experiment has shown that if boiler tubes are increased in length without any increase in diameter, there is a point beyond which the lengthening of a tube fails to produce a proportional increase in evaporation. For best results, the tubes should be extended fully up to the point where the increase in evaporation ceases to be proportional to the increase in length. It has been found on the Pennsylvania that the most desirable length for a tube is about 100 times its internal diameter, and this rule has been adopted, with a leeway to the designer of 10 or 15 per cent to satisfy other boiler conditions.

In the final form of the locomotive (E6s), the original 14-in.-diameter piston valve was replaced by a 12-in., which has been found to be practicable, because superheated steam flows through the steam passages with greater freedom than saturated steam of the same pressure.

The reciprocating parts are very light, and, although the maximum weight on a pair of drivers is now 67,000 lb., the dynamic augment at 70 miles an hour is less than 30 per cent of the static weight on the drivers.

The article describes the tests in detail. Because of lack of space only the outstanding features can be here reported.

The tests in this instance (No. 51) are throughout compared with previously published tests of the older type locomotive No. 89 (locomotives of the latter type are no longer in service).

Fig. 7 shows comparisons between the evaporations per pound of coal at all rates of evaporation. This shows improved results for No. 51 up to the maximum rate where the two lines meet. The maximum rate of equivalent operation for No. 51 is 17.22 lb. per sq. ft. of heating surface per hour.

The shorter-tube boiler showed a great activity of combustion for light drafts, but there was very little difference in the rapidity of evaporation in the two boilers until a draft of 5 in. of water was obtained back of the diaphragm. The shorter-tube boiler thus showed a more rapid rate until its evaporation limit was reached.

As regards engine performance, the efficiency tests made at the testing plant were at speeds between 28.1 miles per hr. (120 r.p.m.) and 84.4 miles per hr. (360 r.p.m.), the nominal cut-offs being between 15 and 50 per cent. At 75 miles per hr. and 35 per cent cut-off, the i.hp. was 2357.2, while in a second series of tests the i.hp. reached 2488.9, or 1 hp. for each 96.5 lb. of total weight.

The coal rate per i. hp-hour did not exceed 3.6 lb. in the first test, and was usually below 2.9 lb.

The steam consumption per i.hp-hour up to 1800 hp. was practically the same for both No. 51 and No. 89. The maximum steam temperature reached (in the branch pipe) was 635.7 deg. fahr., or 251.3 deg. superheat, but in general the superheat was below 230 deg. fahr. Considering the efficiency of the engine, and taking the Rankine cycle as a base for an ideal engine, it is found that the actual engines developed an efficiency which was 67.8 per cent of the ideal.

The maximum drawbar or dynamometer hp. obtained was 2250.5, with the coal rate of 3.8 lb. per dynamometer hp-hour and the steam rate of 19.8 lb. In the curves of the drawbar pull, Fig. 8, the advantage of the larger cylinders of No. 51 is in evidence, the greater drawbar pull being maintained by this engine at every speed up to 85 miles per hour. An interesting feature of the drawbar-pull tests is shown in Fig. 9. The straight lines show the drawbar pull at the various cut-offs given, and indicate a falling off in pull as the speed increases. It is believed that this effect is due to losses of pressure in the cylinder as the piston speed increases. (*The Railway Age Gazette*, vol. 62, no. 12, March 23, 1917, pp. 635-640, 12 figs. *eA*)

Refrigeration

High-Speed Ammonia Compressors, C. R. Neeson

The writer discusses the reason for using high-speed ammonia compressors and the main features of their design.

In regard to the latter he states that the only type of valve feasible is one consisting of a thin plate of special steel to cover a series of slots in the valve cage, which gives a maximum opening with a very small lift, thus allowing a rapid movement of the valve without shock or noise. As the valves must be as small as possible they are placed radially in the cylinder body at each end, suction valves at the top and discharge valves at bottom. All valves are alike and interchangeable.

A special principle has been adopted in order to completely fill the cylinder to suction-pipe pressure. This is a series of ports around the center of the cylinder casting which are uncovered by the piston at the end of the suction stroke when its speed is least and its acceleration greatest, and where the inertia of the gas in the suction pipe tends to build up the pressure at the cylinder. The length of the piston is about the same as its stroke. As there are no valve springs to overcome, it is possible in spite of the so-called high speed to fill the cylinder to the exact pressure in the suction line. Several diagrams are shown to prove this statement. These diagrams show that the pressure in the suction pipe at the

COMPOSITION AND PROPERTIES OF COMMERCIAL LIQUID AMMONIA, E. C. McKelvy and C. S. Taylor

The present paper is a progress report presented at the Twelfth Annual Meeting of the American Society of Refrigerating Engineers in December, 1916, published by permission of the Director of the Bureau of Standards.

As part of the work of the Bureau of Standards upon the determination of the physical constants of ammonia, especially those which are of importance in refrigeration, an investiga-

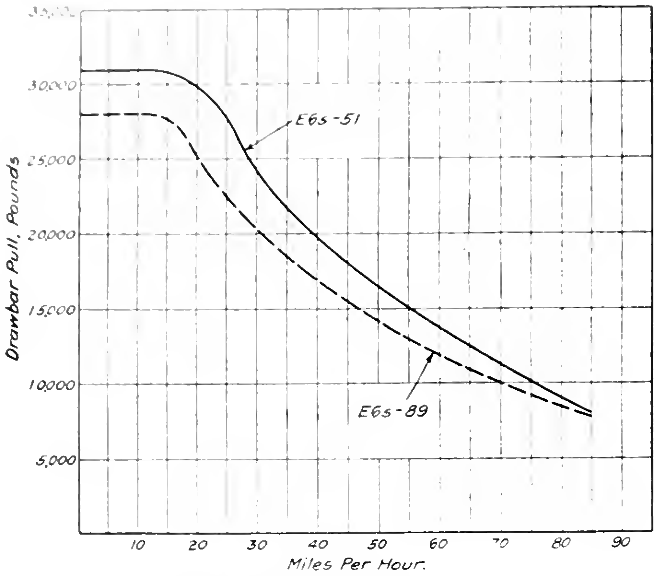

FIG. 8 DRAWBAR-PULL CURVES

tion was undertaken, one of the objects of which was "the acquisition of the necessary information regarding the state of the methods of testing and analysis of liquified ammonia" in industrial use.

The present investigation covered the determination of the impurities in commercial ammonia, the methods of sampling, methods of analysis, and standards of quality.

As regards the composition of commercial ammonia, the results of the present investigation indicate that about two-thirds of the samples examined are about equally suitable as the starting material for the preparation of pure ammonia to be used in exact chemical and physical work.

The results of chemical analysis indicate the adequacy of the simple evaporation test as conducted in many works in detecting samples of poor quality, but such a test is useless in differentiating the majority of the samples now on the market.

The following tentative specification for liquid ammonia is offered. It is based upon determinations that can be carried out in the chemical laboratory, and will insure the delivery of high-grade material. In large shipments where the testing of each drum is out of question, only a general indication of the quality can be obtained by examination of the contents of a few drums chosen at random.

1 The gas drawn from the cylinder (gas phase) on the first opening must contain per 100 grams of ammonia not more than 30 cc. of non-condensing gas (gas unabsorbed by 0.2 N sulphuric acid).
2 The residue on free evaporation of the liquid ammonia, with due precaution for excluding moisture and contamination of the sample on drawing, must be not more than 0.03 per cent.
3 The amount of aromatic amines estimated as pyridine must be not more than 0.001 per cent; the amount of organic acids estimated as acetic acid must be not more than 0.005 per cent.
4 The total organic material converted into carbon dioxide must not give more than 30 milligrams of carbon dioxide per 100 grams of ammonia.

A brief bibliography is appended. (*A. S. R. E. Journal*, vol. 3, no. 5, March 1917, pp. 30-49, 2 figs. *ep*)

LATENT HEAT OF AMMONIA, Gardner T. Voorhees

Derivation by a new method of the values of the latent heat of ammonia.

The writer establishes in the first part of his article formulæ for the latent heat of ammonia or other similar substances.

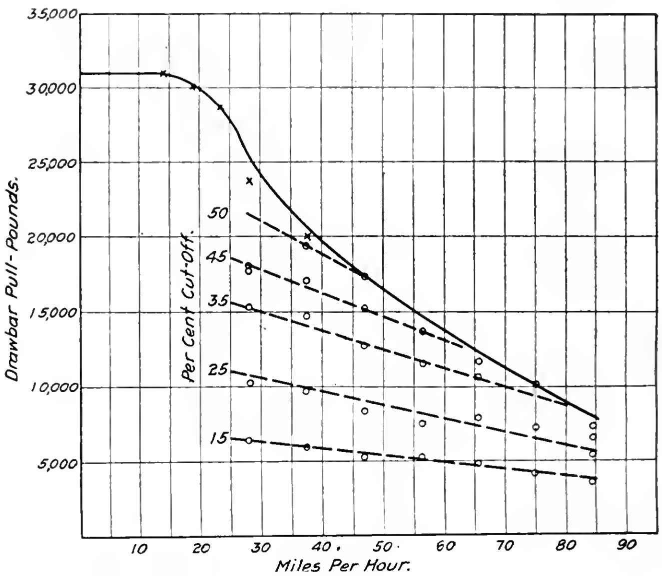

FIG. 9 MAXIMUM DRAWBAR PULL AT VARIOUS CUT-OFFS

From this he proceeds to the derivation of the curves shown in Fig. 10. This work is substantially based on the data of tests made by Professor J. E. Denton, and published in Trans. Am. Soc.M.E., Vol. 12.

Professor Denton gives all the figures for his tests on brine meters and the ammonia meter, but uses a fixed coefficient. Since, however, the brine coefficient for brine meter will vary with the quantity, the present writer has surveyed coefficients from his actual meter tests, and thus obtained slightly different weights of brine circulated. Similarly, a variable coefficient has been derived and used for the ammonia meter.

Tests 2 and 4 of Professor Denton had estimated temperatures for the liquid to the expansion valve. The writer reëstimated these temperatures by a different method and deduced the same results as Professor Denton.

The heat balance as figured by Mr. Voorhees showed about 4 per cent for test 2, about 3 per cent for test 4, and about 3

per cent for test 8, more heat given to the ammonia than taken from it. A correction of less than a fraction of one per cent of the quantities involved was further made for the exposure of the condenser.

On the basis of the above considerations has been plotted on Fig. 10 the curve of high latent heats of condensation. The low latent heats of vaporization, figured by taking the difference in heats of liquid from the latent heat, are shown at 2, 4, 8*l* in the same figure.

Any peculiarities in the action of the ammonia would not have any material effect on the latent heat, and therefore the writer has averaged the three high latent heats and their corresponding saturated temperatures given as 2, 4, 8*h* in Fig. 10. Next the author applied two previously derived equations and has deduced therefrom the approximate latent heats for all conditions from the freezing point of ammonia to its critical temperature. The approximate curve of latent heat is not shown.

The average high-temperature latent heat as represented by point 2, 4, 8*h* of Fig. 10 is at 79 deg. and is 504 B.t.u., the value deduced from Denton's tests by the present writer for this latent heat.

The writer has also plotted a curve not shown here which is the average of the low-temperature latent heats deduced from Denton's tests and equal to 564 B.t.u. The low-temperature latent heat was below the curve above referred to. This occurred because the energy that was dissipated in passing the

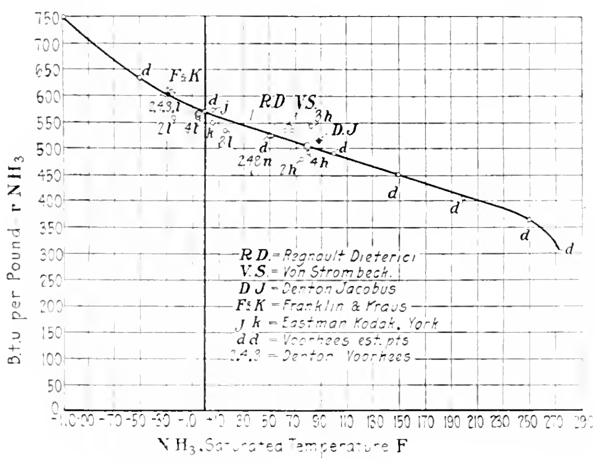

FIG. 10 LATENT HEAT OF AMMONIA (—108 TO +273° F.)

expansion valve was not taken into consideration, and this energy is equal to the euergy that we would have had, if we had had an expansion cylinder. This energy loss at the expansion valve is made up of two parts: First, the energy that would have been required to get the liquid back from the cylinder into compression chamber from the low pressure to the high pressure; and second, the work that would be required to saturatedly compress vapor formed at the expansion valve from the low to the high pressure, and push the resultant liquid back into the proper chamber. The writer gives formulæ for the loss of heat by dissipation at the expansion valve.

A still further important correction is suggested for the latent heats. Up to this point it has always been estimated that the evaporation at the expansion valve was due to the difference of heats of liquid, as if the latent heat used for so doing was entirely at the low pressure.

To determine this the writer deduced successive new curves with successively closer approximations to the true average latent heat, and continued this process until any further approximate curves would make less than 1 B.t.u. difference at any point. These points gave what is believed to be the true latent heat of ammonia as it would actually be in a practical refrigerating system, because its foundation is laid on actual, very accurate tests of a practical refrigerating system and the deductions therefrom based on what is believed to be sound thermodynamic reasoning.

These points have been plotted on Fig. 11 and joined with a smooth curve.

The article gives equations for useful refrigeration with an expansion-valve refrigerating cycle, and a table of figures on

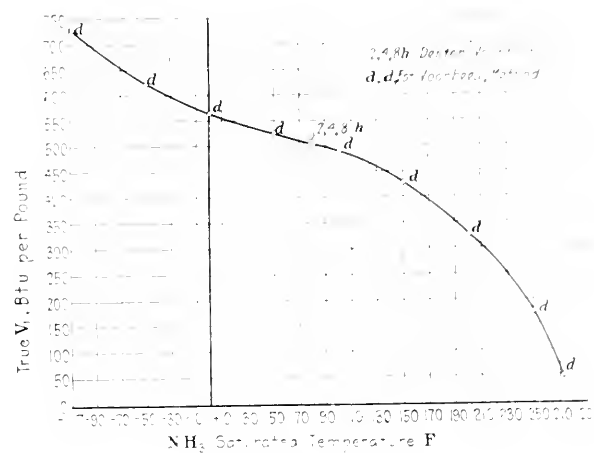

FIG. 11 TRUE LATENT HEAT, FREEZING PT. TO CRITICAL TEMP.

practical latent heat of ammonia-reproduced in Table 3. (*Ice and Refrigeration*, vol. 52, no. 4, April 1917, pp. 177-183, 3 figs., *etA*)

Safety Engineering

GLASSES FOR PROTECTING THE EYES FROM INJURIOUS RADIATIONS, W. W. Coblentz and W. B. Emerson

The object of the present paper is to give the general characteristics of certain newly developed glasses sometimes used for protecting the eye from radiant energy, especially the infra-red or so-called heat rays. Because of the difficulty in reproducing the same color in different melts, no attempt is made to give specific data on the transmission for a given thickness of glass. In order to obtain exact data it is necessary to examine samples from each melt.

These data are representative of an extensive group of glasses available for protecting the eye from (1) the ultra-violet, (2) the visible and (3) the infra-red rays.

For protecting the eye from ultra-violent light, black, amber green, greenish-yellow, and red glasses are efficient. Spectacles made of white glass afford some protection from the extreme ultra-violet rays which come from mercury-in-quartz lamps, and from electric arcs between iron, copper, or carbon. The vapors from these arcs emit but little infra-red radiation in comparison with the amount emitted in the visible and in the ultra-violet rays.

For shielding the eye from infra-red rays deep black, yellowish-green, sage green, gold-plated, and bluish-green glasses are efficient. For working near furnaces of molten iron or glass, if considerable light is needed, a light bluish-green or sage-green glass is efficient in obstructing the infra-red rays. For working molten quartz, operating oxy-acetylene or elec-

for welding apparatus or other intense sources of light, it is important to wear the darkest glasses one can use, whether black, green (including gold-plated glasses) or yellowish green, in order to obstruct not only the ultra red, but also the visible and the ultra violet rays.

Data are given showing that of the infra-red rays emitted by a furnace heated to 1000 to 1100 deg. cent. (1) about 99 per cent are obstructed by gold-plated glasses, (2) about 95 per cent by sage-green or bluish-green glasses, (3) about 80 per cent by very-deep-black glasses, and (4) about 60 per cent by greenish-yellow glasses.

At higher temperatures these data would be somewhat different, but not sufficiently so to modify the rough estimate dealt with in this paper. (*Bureau of Standards*, Technologic Paper No. 93, November, 1916.)

Steam Engineering

Energy Stored in a Boiler Under Pressure, F. R. Low

An interesting discussion of the computation of the energy that would be released by an exploding boiler per pound of contained water and steam.

It is known that when steam separates from water out of which it is generated, a certain amount of work is necessary to overcome the atmospheric pressure. If the pressure per square foot be called p, and the difference in volume between that of the original water and the final volume of water and steam be called u, the pressure being in pounds per square foot, and the volume in cubic feet; if, further, the mechanical equivalent of heat be denoted by A, then the external work done in forcing back the environment when water changes to steam will be Apu (in foot-pounds).

The writer asks whether this Apu work should be included in calculating the energy released by a pound of water under the assumed conditions. There is no doubt that the Apu work is exerted upon the environing atmosphere, but pushing it back is all that it can do. Apart from that, any damage that is caused or any disturbance that is produced must be at the expense of other heat units. The Apu work in itself simply means the generation of a certain volume against the atmospheric pressure, so that as far as the computation of energy released is concerned, i.e., energy available for damage or disturbance, it would appear that the Apu work should not be included.

It makes a difference, however, how the case is stated, and *Power*, in its editorial work, has found such disagreement among authorities that it has asked a score or more of authorities what the value would be for 115 lb. absolute and 212 deg.

The writer presents the matter in the following way.

Imagine a pound of water heated to 338.1 deg. fahr. in a non-conducting cylinder and retained under 115 lb. per sq. in. absolute pressure by a diaphragm as in Fig. 12. Suppose the diaphragm burst. Further, assume that the cylinder, instead of being open as in Fig. 12, was closed at the top, with a partition, as in Fig. 14, the space between the partition and the diaphragm retaining the water being vacuous.

When the diaphragm broke, the mass of steam and water would be projected against the partition. But the partition and the containing wall are assumed to be non-absorptive and impervious to heat, and therefore the heat represented by the kinetic energy, the energy of motion of the projected mass, is reconverted by impact and eddying and friction into heat, and is applied to evaporating more of the water than as though it went off in the energy of flying masses. In this case the entire energy is available for evaporating water.

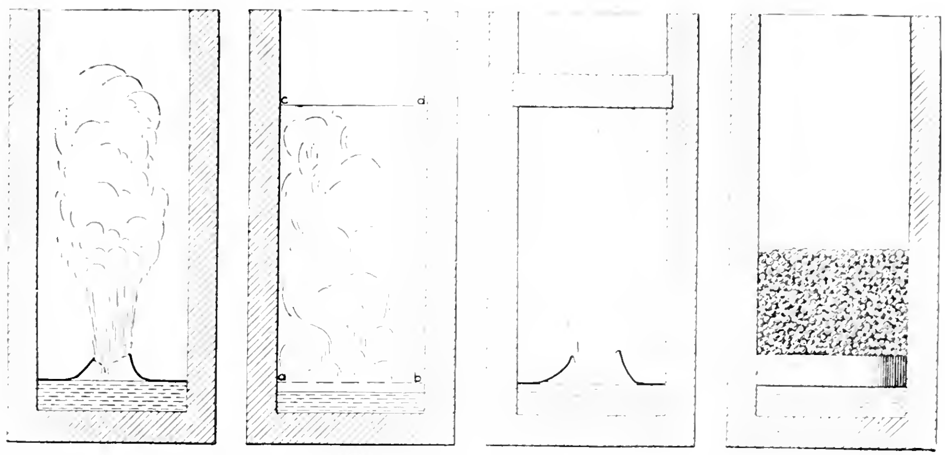
Let us imagine the case as shown in Fig. 15, in which a frictionless and weightless but still non-conducting piston over the liquid is loaded with, say, 100 lb. of shot per sq. in., with its area exerting upon the water the combined pressure of the shot and the atmosphere, 115 lb. per sq. in., and allowing it to be heated to 328.1 deg. without boiling. If now some of the shot is removed, the pressure will become less and the water will boil until, by evaporation, its temperature is reduced to the boiling point under the new pressure. When the shot is all removed, there will be only the atmospheric pressure upon the mixture, and the temperature will be 212 deg. Of the 309 B.t.u. in the pound of water at 115 lb., 180 are in the mixture of steam and water at 212 deg.; 8.87 are represented by the work of raising the piston against the atmospheric pressure, and the rest are consumed in making a part of the water into steam and lifting the shot.

The question raised by the author is whether the 8.87 B.t.u. used to push back the atmosphere is to be credited to the effective work of this steam. This question is answered in the following manner.

Imagine a pound of steam at 115 lb. to change places with an equal volume of free atmosphere. All that it can do is to expand, to generate energy equivalent to the portion of the pressure-volume diagram, Fig. 16, beneath the expansion line; the area *BCDEB*. The energy represented by *ABEFA* was generated when the steam was made and is developed during the admission of this pound of steam into an engine cylinder or turbine nozzle by the simultaneous generation of an equal volume of steam in the boiler, pushing this one out; otherwise the pressure would not remain constant. A pound of steam changing places with an equal volume of free atmosphere can do none of this work; it can simply expand, and if the expansion is adiabatic or isentropic (that is, without the gain or loss of heat), the heat accounted for will be the same in the initial and final conditions.

The internal heat (that is, the difference between the total

heat and the heat equivalent of the Apu work) is given in the tables under the designation E, and since the action is by definition to take place without gain or loss of heat, the difference between these internal or intrinsic heat energies before and after expansion will be the heat equivalent of the work performed; that is, of the area *BCDEB*. For a pound of dry saturated steam at 115 lb., this is given by the table as 1106.5 B.t.u. After expansion, if it were still all steam, we could take the tabular value of E at the lower value away from 1106.5 and find the heat available for performing work. But during the expansion a part of the steam will have condensed and the quality and consequent internal energy will have to be computed.



Figs. 12 to 15 Methods of Change of Water, from 115 lb. and 338 deg. to Atmosphere and 212 deg.

The difference between the internal, or inherent, energies in the initial and final conditions, x_2 in this case being 0.885, is

$$E_1 - E_2 = 1106.5 - 974.34 = 132.16 \text{ B.t.u.}$$

This is represented by the area *BCDEB*. *Power* asked if the person addressed agreed that the energy released (that is, available to produce disaster and disturbance) is that represented by this whole area, or whether it should be reduced by taking out that represented by the area *HCDEH* (that is, the energy absorbed in pushing back the atmosphere with a pressure proportional to *CD* through a volume proportional to *ED*); in other words, whether for the case of the steam the energy available for damage and disturbance should be taken as that represented by the area *BCDEB* or by the shaded area *BCH*. (*Power*, vol. 45, no. 15, April 10, 1917, pp. 475-477, 6 figs. *t*)

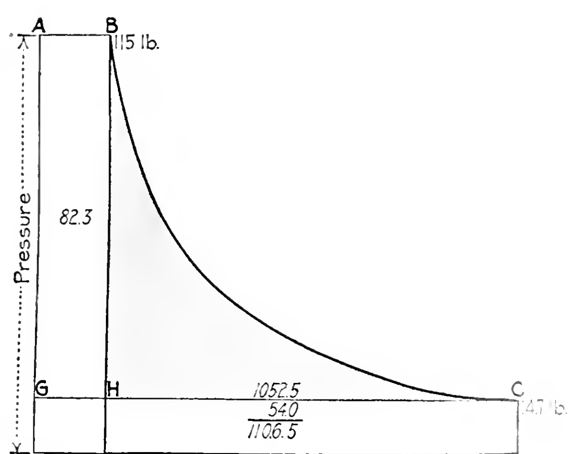


Fig. 16 *PV* Diagram for Steam

Thermodynamics

Exhaustive Tests on Electric Water Heaters, Stanley V. Walton

The article gives details of tests of various types of electric water heaters. It is of considerable interest to mechanical engineers in view of the fact that incidentally valuable data were obtained on heat-transfer phenomena.

Among other things tests were run on heat-insulating materials, in particular, the so-called Economy boiler covering. This material consists of hair felt sewed up in canvas jackets, formed to fit a standard 30-gal. domestic boiler and held in position by lacing. A single-ply covering consists of a single jacket 1 in. thick. The three-ply covering consists of three separate concentric jackets applied one over the other. The magnesia was applied in the form of bricks to a total thickness of 2 in. with an outer cloth covering.

The purpose of the test was to determine radiation losses from the boiler alone, disconnected from all piping. For this purpose the boiler was insulated and filled with water which was heated approximately to the boiling point and the time-temperature curve in cooling was determined. From this curve and known quantity of water the radiation loss can be readily calculated. The results of the tests are given in Fig. 17.

Another test was run on uninsulated boilers, either bare or painted, and the results are given in Figs. 18-19.

A number of similar tests on heat losses from water piping, either bare or insulated, were run, the results being given in the form of curves. (*The Journal of Electricity*, vol. 38, no. 7, April 1, 1917, pp. 227-235, illustrated. *e*)

Varia

Intake Well at the Dubuque Electric Company's Plant, E. M. Walker

General description of the central power station at Dubuque, Iowa. This station has been recently reconstructed

...ized without interruption of service and now has a generating capacity of 9,400 kw.

An interesting feature of the station is an intake well shown in cross-section in Fig. 20. The station is located on a slough of the Mississippi River, about 2,000 ft. away from the main river, and the supply of water for the condensers was a source of trouble for a number of years. The new well has

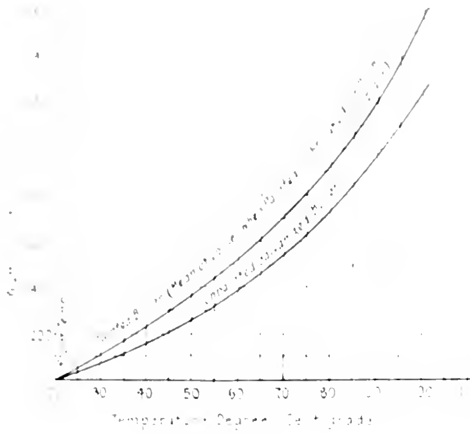

Fig. 17

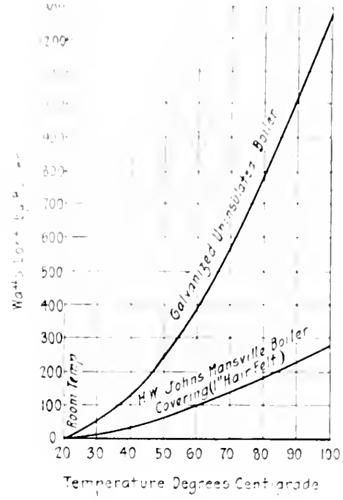

Fig. 18

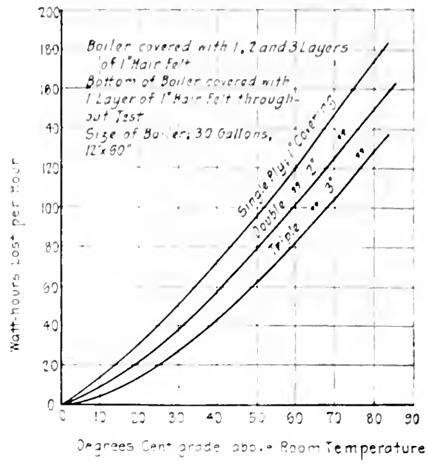

Fig. 19

FIG. 17 RADIATION LOSSES FROM BOILER. FIGS. 18 AND 19 HEAT LOSSES WITH UNINSULATED BOILERS

provided a solution and removed the possibility of a scarcity of water at low stages of the river, which frequently occurs in midwinter and late midsummer.

This well is designed to overcome the difficulty of low water, and also by the whirlpool action of the water in passing through the well to remove automatically a large percentage of the sediment in the river water. The well is built on the spiral principle, the water traveling around it many times, and thus allowing the sediment to settle into a sump in the center, from which it can be periodically removed by an ejector pump.

The well is 20 ft. in diameter and 36 ft. deep, the bottom

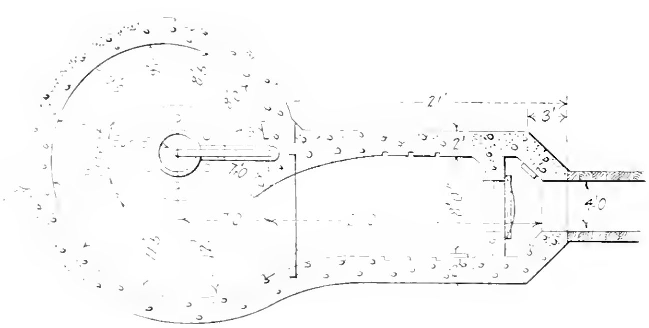

FIG. 20 CROSS-SECTION OF INTAKE WELL

being 6 ft. below zero stage of the river. The intake pipe is 36-in. flanged cast-iron. (*Electrical Review and Western Electrician*, vol. 70, no. 12, March 24, 1917, pp. 485-487, 6 figs., *d*)

RUSSIAN TESTS OF BRITISH TRUCKS, R. Douglas-Vickers

Some time last November the Russian Purchasing Commission in England arranged for trials of commercial vehicles, so as to give British makers an idea of the unusually severe conditions to be met with in Russia where roads are in most cases either poor or entirely absent.

All the vehicles submitted for the test had to carry a 30 per cent overload over an exceptionally poor stretch of ground. The heavy machines were unable to negotiate several stretches of very soft ground, while the lighter machines were better able to get over the difficult places.

It is believed that this test showed the British makers that, if the bad stretches of road referred to were anything like those which were commonly met in Russia, the Russian Commission was fully justified in calling for special requirements. These special requirements are as follows:

- More powerful engines
- Stronger frames and springs
- Greater clearance
- Larger wheels and twin tires on all rear axles for passenger cars
- Especially strong bodies
- Accessibility of all parts for repairs and simplicity to enable repairs to be effected without carrying a large amount of special material.

The writer believes that vehicles used on bad roads should not be of greater load capacity than 5000 lb., should drive on all four wheels, and if not, some means of locking the differential should be provided. (*The Commercial Vehicle*, vol. 16, no. 5, April 1, 1917, p. 23, *g*)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer.

Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquiries for further information in connection with articles reported in the Survey.

EXFOLIATION AND CARBON CONCENTRATION IN CASE-HARDENING OF STEEL, Edwin P. Stenger. Metallurgical and Chemical Engineering, vol. 16, no. 8, April 15, 1917, pp. 42[illegible], 10 figs.

HEAT TREATMENT OF LOW AND HIGH CARBON STEEL BY GAS, W. H. Ehlers. The Gas Age, vol. 39, no. 6, March 15, 1917, pp. 292-296.

THE ELECTROLYTIC PICKLING OF STEEL, M. De Kay Thompson and O. L. Mahlman. A paper to be presented at the Thirty-First General Meeting of the American Electro-Chemical Society, Detroit, May 2-5, 1917.

TESTING DUCTILE QUALITY OF SHEETS AND WIRE. The American Drop Forger, March 1917, pp. 89-93.

THE MICROSCOPIC STUDY OF NON-FERROUS METALS AND ALLOYS—IV, ALUMINUM ALLOYS, Ernest J. Davis. The Metal Industry, vol. 10, no. 10, March 9, 1917, pp. 221-224, figs. 27-33.

SHRINKAGE AND TIME EFFECTS IN REINFORCED CONCRETE, Frank R. McMillan. Studies in Engineering, The University of Minnesota, no. 3, March 1915.

PLASTIC CEMENTS, J. B. Barnitt. Metallurgical and Chemical Engineering, vol. 16, no. 6, March 15, 1917, pp. 321-323.

CORK—ITS ORIGIN AND USES, H. W. Prentiss, Jr. S. A. E. Bulletin, vol. 11, no. 6, March 1917, pp. 679-695.

THE VULCANISATION OF RUBBER BY AGENTS OTHER THAN SULPHUR, Henry P. Stevens. Journal of the Society of Chemical Industry, vol. 36, no. 3, February 15, 1917, pp. 107-109.

PROTECTIVE COATINGS: JAPANS AND ENAMELS—II, E. P. Later. The Foundry, vol. 45, no. 4, whole no. 294, April 1917, pp. 138-140.

FIRE PROTECTION

REPORT OF THE COMMITTEE ON GRADING WATER WORKS WITH REFERENCE TO THEIR VALUE FOR FIRE PROTECTION. Journal of the New England Water Works Association, vol. 31, no. 1, March 1917, pp. 6-11.

FORGING

LE FORGEAGE MÉCANIQUE DES GROSSES CHAINES, P. C. Le Génie Civil, Trente-Septième Année, tome LXX, no. 11, No. 1805, 17 Mars 1917, pp. 169-171, 10 figs.
Mechanical forging of large chains.

DROP-FORGING AT CREWE LOCOMOTIVE WORKS, LONDON & NORTH-WESTERN RAILWAY. The Railway Age Gazette, vol. 26, no. 10, March 9, 1917, pp. 301-4, 6 figs.

FOUNDRY

THE AMERICAN FOUNDRY IN A TIME OF WAR, Edgar Allen Custer, Jr. The Foundry, vol. 45, no. 4, whole no. 294, April 1917, pp. 127-130.

NEW CONVERTER PLANT FOR ECONOMICAL OPERATION. The Foundry, vol. 45, no. 4, whole no. 294, April 1917, pp. 133-137, 9 figs.

ELECTRIC FURNACE PRACTICE IN THE MANUFACTURE OF STEEL CASTINGS, T. S. Quinn. The Electric Journal, vol. 14, no. 4, April 1917, pp. 140-141, 1 fig.

DRAWING THIN-WALLED CORKS AND SPOUTS, A. E. Sanford. The American Drop Forger, March 1917, pp. 73-74.

FUEL AND FIRING

L'UTILISATION DU LIGNITE COMME COMBUSTIBLE, Daniel Bellet. Revue Générale des Sciences Pures et Appliquées, 28e Année, no. 4, 28 Fevrier 1917, pp. 118-124.
Utilization of lignite as a fuel.

BY-PRODUCT COKE AND COKING OPERATIONS, C. J. Ramsburg and F. W. Sperr, Jr. Journal of the Franklin Institute, vol. 183, no. 4, April 1917, pp. 391-432, 33 figs.

THE USE OF KEROSENE AND ALCOHOL IN THE GASOLINE ENGINES INSTALLED IN THE FORTIFICATIONS OF THE UNITED STATES, Capt. Chas. O. Schudt and 1st Lt. John W. Wallis. Journal of the United States Artillery, vol. 47, no. 1, January-February, whole no. 143, pp. 24-35.

RESULTS OF THE GOVERNMENT'S TESTS ON GASOLINE. National Gas Engine Association Bulletin, vol. 2, no. 8, March 1917, pp. 8-12.

INFLAMMABILITY OF CARBONACEOUS DUSTS IN ATMOSPHERES OF LOW OXYGEN CONTENT, H. H. Brown and J. K. Clement. The Journal of Industrial and Engineering Chemistry, vol. 9, no. 4, April 1917, pp. 347-349, 1 fig.

THE "WELLMAN" FURNACES, Messrs. Wellman, Seaver and Head, Ltd., Engineers, London. Engineering, vol. 103, no. 2671, pp. 218-9, 15 figs.

THE ABSORPTION OF OXYGEN BY COAL, J. Ivon Graham, B. A. Transactions—Institution of Mining Engineers, vol. 52, part 3, February 1917, pp. 248-254.

THE FUELS OF TEXAS, A. C. Scott. Coal Age, vol. 11, no. 15, April 14, 1917, pp. 658-661.

HOISTING AND CONVEYING

[illegible] W[illegible], W. W[illegible]. Proceedings of the South Wales Institute of Engineers, vol. [illegible], no. 1, pp. [illegible]-61, 29 figs.

[illegible] Baltimore & Ohio R. R., at [illegible]. Railway Review, vol. 60, no. 1[illegible], March 24, 1917, pp. 409-41[illegible].

[illegible] from Exhaust of Suction Gas Producers. American Gas Engineering Journal, vol. 106, no. 12, whole no. [illegible], March [illegible], 1917, pp. [illegible].

Some Notes on Efficiency and Cost of Steam and Electric Winding Plant, Harold W. Clayden, A.M.I.E.E. The Transactions of the South African Inst. of Elec. Engineers, vol. 7, part 10, December 1916, pp. [illegible].

HYDRAULICS

W[illegible] Mains, F. E. Lungren. The Gas Industry, vol. 17, no. 4, April 1917, pp. 292-296, 4 figs.

Motion of Fluids When the Flow is not Irrotational, G. I. Taylor. Proceedings of the Royal Society, Series A, vol. 93, no. A 648, Mathematical and Physical Sciences, pp. 99-113.

On the Dynamics of Revolving Fluids, Lord Rayleigh. Proceedings of the Royal Society, Series A, vol. 93, No. A 648, Mathematical and Physical Sciences, pp. 148-154.

Flow of Fluids and Frictional Resistance in Pipes—I, J. M. Spitzglass. The Armour Engineer, vol. 9, no. 3, March 1917, pp. 223-231, 2 figs.

Mathematical Note on the Fall of Small Particles through Liquid Columns, Prof. C. G. Knott. Proceedings Royal Society of Edinburgh, Session 1915-16, parts 3 and 4, vol. 36, pp. 237-239.

Sur le calcul des grands surpressions dans les conduites munies d'un reservoir d'air, M. C. Carmichel. Comptes Rendus des Seances de l'Académie des Sciences, Tome 164, no. 8 (19 Fevrier 1917) pp. 331-333.

Computation of large peak pressures in conduits provided with air reservoirs.

The Test and Study of the Hydraulic Shunt Flow Tube, W. R. Spencer and A. d'Amorin. The Rose Technic, vol. 26, no. 6, March 1917, pp. 176-181.

Cement Joints for Cast-Iron Water Mains, Clark H. Shaw. Proceedings of the American Society of Civil Engineers, vol. 43, no. 3, March 1917, pp. 432-443, illustrated.

Synopsis: Method of Making the Joint; Removing Cement; Jointed Pipes.

INTERNAL-COMBUSTION ENGINEERING

Special Cams Designed for Aluminum Engine of Premier, A. L. Nelson. The Automobile, vol. 36, no. 14, April 5, 1917, pp. 689-692, 6 figs.

Improving Design of Waterjackets, J. Edward Schipper. The Automobile, vol. 36, no. 13, March 29, 1917, pp. 642-644, illustrated.

Piston Design, with Special Reference to Aluminum Pistons, Harry R. Ricardo. The Automobile Engineer, vol. 7, no. 100, March 1917, pp. 60-63, 5 figs.

A "slipper" type piston.

Crankshaft Problems in Automobile Engines, A. P. Brush. The Gas Engine, vol. 19, no. 4, April 1917, pp. 178-185, 7 figs.

Continental Engines. The Automobile, vol. 36, no. 11, March 15, 1917, pp. 560-564.

LUBRICATION

Lubrication of Superheated Engines. Railway and Locomotive Engineering, vol. 30, no. 4, April 1917, pp. 112-114.

Valve Stem Lubricators. The Autocar, vol. 38, no. 1115, March 3, 1917, pp. 224-225.

MACHINE PARTS

Gearing Development through Treatment, W. H. Phillips. The Blast Furnace and Steel Plant, April 1917, pp. 152-154.

Determination of Spring Length, an Empirical Method Based upon the Substitution of One Spring for Another of the Same or a Different Type—II, David Landau and Asher Golden. The Horseless Age, vol. 40, no. 1, April 1, 1917, Engineering Section, pp. 4-8, 6 figs.

MACHINE SHOP

Shafting and Belting for Machine Shops, Joseph Horner. The American Drop Forger, March 1917, pp. 83-89.

Workshop Precision Grinding, H. H. Asbridge. The Mechanical Engineer, vol. 39, no. 1001, March 30, 1917, pp. 240-244, figs. 9-15 (continued).

MARINE ENGINEERING

Marine Machine Shop Equipment, Tools Ranging from the Smallest and Finest to the Largest and Heaviest Required in Shipyard Machine Shops, W. D. Forbes. Marine Engineering, vol. 22, no. 4, April 1917, pp. 179-181.

Four Year Test of Motorship Fleet. The Marine Review, vol. 47, no. 4, April 1917, pp. 122-124.

Improvements in Marine Engine Room and Fire Room Auxiliary Machinery. Marine Engineering, vol. 22, no. 4, April 1917, pp. 140-145, 16 figs.

The Future Ship, A Motor Vessel. The Motor Boat, vol. 14, no. 7, April 10, 1917, pp. 12-16.

1. Full Powered Motorship, D. W. and R. Z. Dickie.
2. The Future and Motorships, H. V. Haymann.
3. The Answer to the U-Boat Blockade, J. Murray Watts.
4. Three Predominant Motor Types, C. S. Snyder.
5. Some of the Advantages, T. W. Campbell.

MEASURING APPARATUS

Scales and Weighing Methods in Industrial Establishments, Herbert T. Wade. Industrial Management, vol. 52, no. 6, March 1917, pp. 817-833, illustrated.

II. Design, Construction, Operation, and Test of Scales of Moderate Capacity.

Pyrometers—Past, Present and Future, Richard P. Brown. The Iron Trade Review, vol. 60, no. 12, March 22, 1917, pp. 671-673.

The Manufacture of Gauges. The Journal of the Institution of Mechanical Engineers, no. 3, March 1917, pp. 57-119, 22 figs.

MECHANICS

On Waves in an Elastic Plate, Horace Lamb. Proceedings of the Royal Society, Series A, vol. 93, no. A 648 Mathematical and Physical Sciences, pp. 114-128, illustrated.

Force and Shrink Fits, Sanford A. Moss. General Electric Review, vol. 20, no. 4, April 1917, pp. 320-332, 5 figs.

La theorie des quanta et sa place dans l'histoire des theories physiques modernes, Daniel Berthélot. Revue Generale de l'Electricité, 1 re année, tome 1, no. 10, 10 Mars, 1917, pp. 363-365.

The theory of quanta and its place in the history of modern physical theories.

Vibration in Buildings Proves Less Where Concrete is Used, Morton C. Tuttle. Cement World, vol. 2, no. 3, March 1917, pp. 40-44.

MOTOR CARS

New Burner in Doble Steamer—Kerosene Flows by Air Pressure from a Float Chamber, Combustion now so Complete that no Soot is Deposited on Generator Tubing. The Automobile, vol. 36, no. 14, April 5, 1917, pp. 700-703, illustrated.

An Analysis of the Tractor Situation, Hugh McVey. S. A. E. Bulletin, vol. 11, no. 6, March 1917, pp. 640-649.

Analysis of Year's Progress as Observed at Automobile Shows, J. Edward Schipper. S. A. E. Bulletin, vol. 11, no. 6, March 1917, pp. 653-672, 1 fig.

MUNITIONS

Projectiles Containing Explosives, Commandant, A. R. United States Naval Institute Proceedings, vol. 43, no. 170, April 1917, pp. 665-681.

Translated from Revue Génerale des Sciences Pures et Appliquées, vol. 27, pp. 213-221, April 15, 1916, by Charles E. Monroe.

Ammunition for American Merchantmen, Lieut. A. G. Dibrell. American Machinist, vol. 46, no. 15, April 12, 1917, pp. 617-625, 28 figs.

United States Munitions, The Springfield Model 1913 Service Rifle, Leaf II. Slide and Cap. American Machinist, vol. 46, no. 15, April 12, 1917, pp. 641-647, illustrated.

Machine Tools Developed for Shrapnel Manufacture. Canadian Machinery and Manufacturing News, vol. 17, no. 13, March 29, 1917, pp. 305-308, 9 figs.

Munition-Plant Poisons, Archie Rice. American Journal of Public Health, vol. 7, no. 3, March 1917, pp. 273-281, 1 fig.

60-Pounder Shell Head. Diverse Methods of Machining. Machinery, vol. 9, no. 231, March 1, 1917, pp. 620-623.

Forging 4.5 Ins. 60 pdr. and 6 Ins. Howitzer Shell. Canadian Machinery and Manufacturing News, vol. 17, no. 15, April 12, 1917, pp. 363-366, illustrated.

POWER GENERATION AND POWER PLANTS

Power Equipment for Blast Furnaces, Charles L. Hubbard. National Engineer, vol. 21, no. 4, April 1917, pp. 134-137, 8 figs.

Power Equipment for Steam Plants: VII—Vacuum Pumps, Cooling Towers and Soot Blowers, Robert L. Streeter. Industrial Management, vol. 52, no. 6, March 1917, pp. 853-868, 24 figs.

Power Equipment for Steam Plants: VIII—Purification, Heating and Pumping Feed Water, Robert L. Streeter. Industrial Management, vol. 53, no. 1, April 1917, pp. 81-99, 27 figs.

Blast Furnace and Steel Mill Power Plants, Richard H. Rice and Sanford A. Moss. Proceedings of the Engineers' Society of Western Pennsylvania, vol. 33, no. 2, March 1917, pp. 81-130, illustrated.

Hydro-Electric Plant of the Cedar Rapids Hydraulic Manufacturing Company at Cedars, P. Q., Henry Holgate (p. 440), Julian C. Smith (p. 449), and R. M. Wilson (469-500), Transactions of the Canadian Society of Civil Engineers, vol. 29, pt. 2, October-December 1915, illustrated.

The Stave Falls Power Development of Western Canada Power Company, Ltd., R. F. Hayward. Transactions of the Canadian Society of Civil Engineers, vol. 29, pt. 2, October-December 1915, pp. 387-437, 29 figs.

Dubuque Electric Company's Plant, E. M. Walker. Electrical Review and Western Electrician, vol. 70, no. 12, March 24, 1917, pp. 485-7, 6 figs.

Dodge Brothers Power Station. Practical Engineer, vol. 21, no. 8, April 15, 1917, pp. 337-340, 5 figs.

RAILROAD ENGINEERING

Pennsylvania Locomotive Tests, Andrew C. Loudon. Railway Mechanical Engineer, vol. 91, no. 4, April 1917, pp. 177-181, 12 figs.

Pennsylvania 58-Ton Hopper Cars. Railway Mechanical Engineer, vol. 91, no. 4, April 1917, pp. 191-194, illustrated.

A Successful Gasoline Locomotive. Coal Age, vol. 11, no. 11, April 7, 1917, pp. 609-110.

Locomotive Fire Boxes. Proceedings of the First Bi-Monthly Meeting, 1917, Southern & Southwestern Railway Club, vol. 14, no. 1, January 1917, pp. 3-40.

The Effect of Fire Box Design Upon Boiler Capacity and Economy, J. T. Anthony. Official Proceedings of the Railway Club of Pittsburgh, vol. 16, no. 4, February 23, 1917, pp. 87-122.

Tests of Western Yellow Pine Car Sills, Joists, and Small Clear Pieces, C. W. Zimmerman. U. S. Dept. of Agriculture Bulletin, no. 497, April 4, 1917, 16 pp.

Babbitt Furnace for Locomotive Shops, D. C. F., Railway Review, vol. 60, no. 13, March 31, 1917, p. 449.

Counterbalancing the Reciprocating and Revolving Parts of Locomotives, Old and New Methods, Location of the Weights Railway and Locomotive Engineering, vol. 30, no. 4 April 1917, pp. 115-117, 9 figs.

Railway Water Supply, C. R. Knowles. New York Railroad Club, Advance copy of paper presented at the meeting of Friday, April 20, 1917, 12 pp.

Convention of Railway Engineering Association. Railway Review, vol. 60, no. 12, March 24, 1917, p. 416-424, illustrated.

Signals and Interlocking—Electricity—Signs—Fences and Crossings—Water Service—Wooden Bridges and Trestles—Stresses in Railroad Track—Conservation of Natural Resources—Track—Ballast—Ties—Roadway—Uniform General Contract Forms—Economics of Railway Location—Yards and Terminals—Records and Accounts—Buildings—Ash Pits—Rail—Grading of Lumber—Masonry—Iron and Steel Structures—Rules and Organization—Wood Preservation—Election.

Pennsylvania Atlantic Type Locomotive Tests, Andred C. Loudon. Railway Age Gazette, vol. 62, no. 12, March 23, 1917, pp. 635-640.

REFRIGERATION

Latent Heat of Ammonia, Gardner T. Voorhees. Ice and Refrigeration, vol. 52, no. 4, April 1917, pp. 177-183.

Heat Balance of an Absorption Plant, Julian C. Smallwood. Power, vol. 45, no. 15, April 10, 1917, pp. 482-484, 2 figs.

Accidents in Refrigerating Plants, John E. Starr. American Society of Refrigerating Engineers' Journal, vol. 3, no. 5, March 1917, pp. 5-14.

High Speed Ammonia Compressors, C. R. Neeson. American Society of Refrigerating Engineers' Journal, vol. 3, no. 5, March 1917, pp. 15-29, 15 figs.

Composition and Testing of Commercial Liquid Ammonia, E. C. McKelvey and C. S. Taylor. American Society of Refrigerating Engineers' Journal, vol. 3, no. 5, March 1917, pp. 30-49, 2 figs.

SAND BLAST

The Sand Blast, Its History and Development. II. Frederick George. Cassier's Engineering Monthly, vol. 51, no. 3, March 1917, pp. 167-175, 10 figs.

STEAM ENGINEERING

Energy Stored in a Boiler Under Pressure, F. R. Low. Power, vol. 45, no. 15, April 10, 1917, pp. 474-477, 6 figs.

Efficiency of Waste Heat Boilers, H. A. Reichenbach. Iron Age, April 12, 1917, vol. 99, no. 15, pp. 902-905, illustrated.

The Composition of Klingerit Steam Packing. The India Rubber World, vol. 51, no. 1, April 1, 1917, pp. 385.

Steam Turbines for Land Purposes. Engineering, vol. 103, no. 2672, March 16, 1917, pp. 244-246 and 248, illustrated.

Uniflow Steam Engine for Rod Mill Drive, Charles C. Lynde. The Blast Furnace and Steel Plant, April 1917, pp. 143-146, 4 figs.

Heat Transmission thru Boiler Tubes, Edwin Allan Fessenden and Jiles William Haney. The University of Missouri Bulletin, vol. 17, no. 26, 74 pp., 30 figs.
Engineering Experiment Station Series 18.

North-East Coast Institution Guidance Specification (1917) for Cargo Boat Triple-expansion Engines. The Shipbuilder, vol. 16, no. 79, March 1917, pp. 108-111.

Feed Water Control—II. Practical Engineer, vol. 21, no. 6, March 15, 1917, pp. 263-264.

Economizers. Practical Engineer, vol. 21, no. 6, March 15, 1917, pp. 265-6.

Use of Mine Water as Boiler Feed, Edwin M. Chance. Coal Age, vol. 2, no. 14, April 7, 1917, pp. 600-601.

THERMODYNAMICS

Exhaustive Tests on Electric Water Heaters, Stanley V. Walton. Journal of Electricity, vol. 38, no. 7, April 1, 1917, pp. 227-235, illustrated.

An Outline of the Theory of Heat Transmission and Absorption in Application to Ordinary Engineering Problems, John E. Bell. Proceedings of The Engineers' Society of Western Pennsylvania, vol. 32, no. 10, January 1917, pp. 797-845.

VARIA

Mobilization of Automobile Industries. S. A. E. Bulletin, vol. 11, no. 6, March 1917, pp. 697-699.

Hiring for Hawthorne, a Few Details Involved in the Job of Giving Out Jobs. Western Electric News, vol. 6, no. 2, April 1917, pp. 6-9, illustrated.

The Economic Efficiency of a Workman, Leonard M. Passano. The Technology Monthly and Harvard Engineering Journal, vol. 3, no. 8, March 1917, pp. 5-13, 4 tables.

Introduction and Definition—Theoretical Formulae: Spoilage Treated as Reducing the Product—Theoretical Formulae: Spoilage Treated as Increasing the Cost—Typical Factory—Varying and Standard Rate of Gain—Efficiency and Bonus—Adjusting Wages or Docking—Conclusion.

Precision Spacing Machine. The Iron Trade Review, vol. 60, no. 13, March 29, 1917, pp. 734-735, 3 figs.

Winter Grinding and Screening, Ernest W. Knapp. Brick and Clay Record, vol. 50, no. 7, March 27, 1917, pp. 635-639, 7 figs.

A Glossary of Terms Used in the Rubber Industry, Frederick Dannerth. Metallurgical and Chemical Engineering, vol. 16, no. 7, April 1, 1917, pp. 380-383.

Chicago's Co-operative Administrative Research, F. M. Simons, Jr. Industrial Management, vol. 53, no. 1, April 1917, pp. 107-117.

Technical Words and Phrases Defined by Special Institute

[illegible] M[illegible], 1917, pp. 54 [illegible]

[illegible] Trade Review, vol. [illegible]

On the S[illegible] Dr. Sven Oden. Proceedings, Royal [illegible] Session 1915-16, Parts III and IV [illegible]

[illegible] Joseph W. Hay. Steam [illegible]

VENTILATION

Ventilation. R. G. Dewardt. The Post Office Electrical Engineers' Journal, vol. 9, pt. 4, January 1917, pp. 317-325, 2 figs.

CHARTS

Latent Heat of Ammonia from 108 deg. Fahr. to 273 deg. Fahr. [illegible] Latent Heats from Ammonia from Freezing Point to the Critical Temperature, Gardner T. Voorhees. Ice and Refrigeration, vol. 52, no. 4, April 1917, pp. 181-182.

Chart Used in Testing Indoor Air Conditions. The Heating and Ventilating Magazine, vol. 14, no. 3, March 1917, p. 39.

Chart for Determining Size of Steam Pipe for Work to Be Done, M. William Ehrlich. Metal Worker, Plumber and Steam Fitter, vol. 87, no. 12, March 23, 1917, p. 388.

Shearing Curves and Work Required for Steel and Other Metals. The American Drop Forger, March 1917, p. 76, 2 figs.

Chart for Figuring Weight of Pipe. The Heating and Ventilating Magazine, vol. 14, no. 3, March 1917, p. 19.

Chart for Calculations Pertaining to Condenser Performance. Power, vol. 45, no. 15, April 10, 1917, p. 497.

Maksimalmomentskurver for Kontinuerlige Bjaelker med konstant Tvaersnit og Fagelaengde og fordelt Last, Prof. E. Suenson. Teknisk Tidsskrift den Tekniske Forening og Elektroteknisk Forening, 46. Aarg. no. 49, 1916, Dec. 6, 1916, pp. 19-22, 3 figs.

Maximum moment curves for continuous beams of constant cross-section and distributed load.

Shearing Curves and Work Required for Cold Rolled Steel, Soft Steel, Brass, Copper. The American Drop Forger, March 1917, p. 76.

Chart to Determine Loss of Coal through Grates, Carleton W. Hubbard. Coal Age, vol. 11, no. 13, March 31, 1917, p. 555.

Curve of K (Coefficient) for Flow of Blast Furnace Gas through Standard Orifices—for Flow of By-Product Coke Oven Gas through Standard Orifices, Coefficient Curves for Stack and Oven Gas, Thos. G. Estep, Jr. The Blast Furnace and Steel Plant, April 1917, pp. 147-148.

Chart Showing Heat Retaining Qualities of Ovens, W. C. Buttner. American Gas Engineering Journal, vol. 104, no. 14, whole no. 3082, p. 319.

Chart Showing Temperatures Obtained with Varying Amounts of Gas, W. C. Buttner. American Gas Engineering Journal, vol. 104, no. 14, whole no. 3082, p. 317.

Curves Showing Most Economical Speed of Steamer of 7000 Tons D. W., the Most Economical Speed of a Merchant Ship. Marine Engineering, vol. 22, no. 4, April 1917, p. 125.

Work vs. Cost (Graphic Chart), J. K. Mason. Industrial Management, vol. 53, no. 1, April 1917, p. 64.

LIBRARY NOTES

PERSONALS

*In these columns are inserted items **concerning members of the Society and their professional activities. Members are always interested in the doings of their fellow-members, and the Society welcomes notes from members and concerning members for insertion in this section. All communications of personal notes should be addressed to the Secretary and items should be received by May 16 in order to appear in the June issue.***

CHANGES OF POSITION

Andrew C. Loudon has accepted a position with the Locomotive Superheater Company, New York. He was until recently associate editor of the *Railway Age Gazette*, New York.

Channing Turner, formerly assistant industrial engineer with the Winchester Repeating Arms Company, New Haven, Conn., has become ranch manager at Clearwater, Mont.

Leon P. Alford is now associated with *Industrial Management*, formerly Engineering Magazine, as editor-in-chief. He was editor of the *American Machinist* for about ten years.

Ralph S. Barnaby, formerly with The Elco Company, Bayonne, N. J., as inspector of material, has joined the engineering department of the Standard Aero Corporation, Plainfield, N. J.

Albert W. Bissell has resigned as assistant sales manager of the American Refractories Company, Chicago, Ill., to enter the employ of the Colorado Fuel and Iron Company, Pueblo, Colo.

David Van Alstyne, until recently assistant to vice-president of the N. Y., N. H. and H. R. R., New York, has accepted a position with the American Locomotive Company, New York.

John W. Brassington, formerly engineer with The Pusey and Jones Company, Wilmington, Del., has assumed the duties of chief engineer of the American Writing Paper Company, Holyoke, Mass.

Charles J. Tehle has accepted a position with the Kerr Turbine Company of Wellsville, N. Y. He was until recently in the employ of the Chicago Pneumatic Tool Company of Franklin, Pa.

La Vern J. Charles, until recently construction engineer with the U. S. Reclamation Service, Lakewood, New Mexico, has assumed the duties of assistant state highway engineer of Santa Fe, New Mexico.

Frederick A. Otto, superintendent of the electrical department of the St. Paul Gas Light Company, St. Paul, Minn., has become affiliated with the Minnesota Gas and Electric Company, Albert Lea, Minn.

James McNaughton has become affiliated with the Eddystone Ammunition Company, Eddystone, Pa., as assistant to the president. He was formerly vice-president of the American Locomotive Company, New York.

P. M. Smith has resigned his position with the William Tod Company of Youngstown, O., to become connected with the Standard Engineering Company of Ellwood City, Pa., in the capacity of chief draftsman.

Andrew Westwater, formerly marine engine and boiler draftsman with the Moore and Scott Iron Works, Alameda, Cal., has be-

come identified with the Columbia River Shipbuilding Corporation, Portland, Ore.

Gilbert I. Vincent has accepted the position of engineer with the Syracuse Lighting Company, Syracuse, N. Y. He was until recently connected with the Des Moines Gas Company, Des Moines, Ia., in a similar capacity.

Forrest E. Cardullo, formerly chief draftsman of the Pierce-Arrow Motor Car Company, Buffalo, N. Y., has assumed the duties of engineer of tests with the Curtiss Aeroplane and Motor Corporation of the same city.

Frederic C. Holmgren, material engineer with The Remington Arms Union Metallic Cartridge Company, Bridgeport, Conn., has assumed the duties of automobile expert with the Rock Island Arsenal, Rock Island, Ill.

Harold E. Rowe has left the employ of The Carborundum Company, Niagara Falls, N. Y., and has again become associated with The Sinclair Refining Company, with headquarters at their main office in Chicago, Ill.

Edwin J. Lanham, formerly employed as mechanical engineer for the Elyria Machine Company, Elyria, O., has recently become associated with the B. F. Goodrich Company, Akron, O., in the capacity of estimating engineer.

Herbert R. Lucke has resigned his position as manager of the De La Vergne Engine Company, Houston, Tex., to assume the duties of vice-president and assistant general manager of the Hughes Tool Company, Houston, Tex.

Frank L. Dalas, formerly with the Youngstown Sheet and Tube Company, Youngstown, O., in the capacity of inspector of the electrical and mechanical department, has become head electrician at the Burma Mines, Burma, India.

Orlo L. Waugh has accepted a position with The Crown Cork and Seal Company, Toronto, Ont., Canada. He was until recently employed by the Curtiss Aeroplane and Motor Company, Buffalo, N. Y., in the capacity of testing engineer.

Thomas M. Roberts has resigned his position as electrical engineer's assistant, Interborough Rapid Transit Company, New York, and has become associated with the Navy Department, Bureau of Yards and Docks, Washington, D. C.

P. T. Sowden has resigned as works manager of the Torsion Balance Company, New York and Jersey City, to accept the position of assistant general manager of Arkell and Smith, Canajoharie, N. Y., manufacturers of paper bag machinery.

Bruce M. Swope has accepted the position of assistant master mechanic of the Renovo Division of the Pennsylvania Railroad Company. He was formerly motive power inspector of the Pitcairn Car Shops of the same company, at Pittsburgh, Pa.

John H. Wynne has assumed the duties of vice-president of E. B. Cadwell and Company, Inc., New York. Mr. Wynne was formerly connected with the American Locomotive Company, New York, in the capacity of sales manager of construction equipment.

Edwin Frank, formerly instructor in mechanical engineering, University of Illinois, Urbana, Ill., has become affiliated with the C. H. Wheeler Manufacturing Company, North Philadelphia, Pa., in the capacity of centrifugal pump designer in the marine department.

R. J. S. Pigott, until recently associated with the Interborough Rapid Transit Co. in a consulting capacity, and for the last two years power superintendent of the Remington Arms and Ammunition Company, has become associated with the Sanford-Riley Stoker Company, New York, in a consulting capacity on [illegible]

ANNOUNCEMENTS

E. C. Henn has been elected one of the directors of the Cleveland Chamber of Commerce.

Sir Robert A. Hadfield has offered 200 pounds to provide for a prize for a new and accurate method for determining the hardness of various metals.

W. B. Gregory, professor of experimental engineering, Tulane University of Louisiana, New Orleans, has been commissioned Major of the engineer section of the Officers' Reserve Corps.

James G. Scrugham, Dean of the Engineering College of the University of Nevada, Reno, Nevada, is to take a two years' leave of absence to accept the position of state engineer of Nevada.

Paul M. Lincoln, Jack S. Herbert and Elmer K. Hiles have received commissions signed by President Wilson, making them officers in the engineering division of the Officers' Reserve Corps of the United States Army.

Paul C. Philipp has taken into partnership H. K. Beach. Mr. Beach has had a wide experience along power plant work and general engineering for industrial concerns, especially designing of brass and copper mills. Mr. Philipp has been in private practice for a number of years, specializing in the valuation of public utility and industrial properties and preparing financial reports. The partnership will be conducted under the firm name of Philipp and Beach, with office headquarters at Philadelphia, Pa.

APPOINTMENTS

Jacob A. Teach has recently been appointed mechanical engineer of the Minneapolis Steel and Machinery Company, Minneapolis, Minn.

AUTHORS

C. R. Knowles presented a paper on Railway Water Supply at the April 20 meeting of the New York Railroad Club.

Julian C. Smallwood has contributed an article on Heat Balance of an Absorption Plant to the April 10 issue of *Power*.

Harold B. Bernard has contributed an article on Natural Gas Pumping Station at Roystone to the April 17 issue of *Power*.

Donald A. Hampson is contributing a series of articles on The Tools of the Automobile Repair Shop to the *Horseless Age*.

Gardner T. Voorhees is the author of Latent Heat of Ammonia, which appears in the April number of *Ice and Refrigeration*.

Charles C. Lynde is the author of Uniflow Steam Engine for Rod Mill Drive, which appears in the April issue of *The Blast Furnace and Steel Plant*.

Calvin W. Rice and Leon Goldmerstein (Cammen) are the joint authors of an article on Mechanical Engineering in *The American Year Book*, 1916.

Alanson P. Brush is the author of an article on Crankshaft Problems in Automobile Engines, which appears in the April number of *The Gas Engine*.

Paul A. Bancel has contributed a brief article entitled World's Two Largest Steam Hoists, to the April 7 issue of the *Engineering and Mining Journal*.

Frederick W. O'Neil is the author of Recent Developments in the Design of Hoisting Engines, which appears in the April 7 issue of the *Engineering and Mining Journal*.

Henry M. Hobart has contributd an article on Electrical Machinery Tests and Specifications Based on Modern Standards to the April issue of the *General Electric Review*.

Allen F. Brewer is the author of an article on The Principles of the Calculation of "Straight Line" Depreciation, which is published in *Industrial Management* for April.

P. C. Idell presented an illustrated paper on Development of Boilers and Modern Boiler-Room Construction at the April 12 meeting of the Engineers' Club of Trenton, Trenton, N. J.

George W. Fuller has contributed to the April 5 number of *Engineering News-Record*, an article entitled Relations Between Sewage Disposal and Water Supply Are Changing, in which an appraisal of progress is made, viewed in the light of recent developments in the field of sanitary engineering.

W. D. Forbes is the author of Marine Machine Shop Equipment, published in the April issue of *Marine Engineering*. This article deals with tools ranging from the smallest and finest to the largest and heaviest required in shipyard machine shops.

Power Losses in Pneumatic Tires by E. H. Lockwood, read before the January 25th meeting of the Pennsylvania Section of the Society of Automobile Engineers, was published in the February Bulletin of the Society of Automobile Engineers, and republished in the February Proceedings of the Philadelphia Engineers' Club, the February 1 issue of *The Automobile* and the March 31 number of *Automobile Topics*.

THE NEW BOOKS

All books received by The Journal will be listed under this heading, generally accompanied by brief descriptive notes. Works of special importance to mechanical engineers will be commented on at length by members and others peculiarly qualified by reason of their experience and training.

Riveted Boiler Joints. By [illegible], B.S., M.S., Member of Boiler Code Committee, Am.Soc.M.E., Chief Engineer, The Hartford Steam Boiler Inspection and Insurance Company. McGraw Hill Book Co., Inc., New York, 1917. Cloth, 11 x 8 in., 52 figures and 75 full page [illegible]. $[illegible] net.

The twofold aim of the author is to give a graphical treatment of riveted joint design and to determine the best arrangement of rivets in a given joint. The graphical treatment is extensive and charts are given for nearly all diameters of rivets used in practice. The method of constructing additional charts is given should there be need for these in cases other than those given in the text. The best arrangement of rivets is attempted by the author, and is indicated by a statement rather than by proof. In this connection the chapter on Riveted Joints of Maximum Efficiency requires much polishing before the treatment becomes clear. The discussion refers mainly to lap joints, and the author does not state always whether the analysis is general or specific, thus leaving the reader to decide this question. If the book is intended for those who do not wish to undertake an intensive study, the previous criticism carries its maximum weight.

According to the author, the book is intended for boiler designers, boiler inspectors, students, and to some extent for structural engineers. For the latter class, however, the book seems to offer little, since structural engineers use rivets mainly in compressive members, and the joints subject to tension are rare.

The treatment is both analytical and graphical. The mathematics required of the reader consists of simple algebraic transformations and only a slight suggestion of analytic geometry. One accustomed to the use of cross-section paper will perhaps meet with little difficulty in plotting the linear equations given in the text. Moreover, the author works out a sufficient number of examples, so that the reader could hardly go astray, even though the explanations are extensive rather than explicit.

The graphical treatment is original, although it has been published previously by the author in the columns of *Power*. A discussion of limiting pitches is given, and this is a desirable asset.

The author does not devote any attention to the question of eccentrically loaded joints. In fact, lap joints are shown with the same prominence as double butt-strap joints with equal-width cover plates. Even the double butt-strap joints with unequal-width cover plates are shown, and these have the same disadvantages as the ordinary lap joints. It will be remembered that lap joints are going out of use rapidly, and in many states are prohibited by law. The reviewer concludes from the text that it makes little or no difference in the author's mind which are to be advocated.

Whether this book will be of service to the designer depends entirely on the designer's point of view. If one wishes to select joints with little or no calculation, the charts are of service. If, on the other hand, the designer prefers to calculate the joints from first principles, the book is of less service, since this part is not given with utmost clearness. One objection to the use of charts for boiler designers is that in drawing them the values of the resistances in tension, shear, and crushing must be fixed. Hence such charts would become obsolete should cases arise in the future when these values might be changed. They may be redrawn for the new values, however. This disadvantage does not hold for the analytical treatment.

Alphonse A. Adler.

Mechanical Equipment of Buildings. Vol. I, Heating and Ventilation of Buildings. By Louis Allen Harding, B.S., M.E., and Arthur Cutts Willard, S.B. John Wiley & Sons, Inc., New York, 1916. Leather, 9¼ x 6½ in., 606 pp., 66 illustrations and charts. $4 net.

Volume I of this work deals with the heating and ventilating of buildings, and subsequent volumes will, it is said, relate to power plants, elevators, lighting systems, refrigerating plants, sprinkler systems, vacuum cleaning, and plumbing. The object of the authors is to produce a reference book for engineers and architects which will contain sufficient theoretical and commercial data for practical use in the designing room, and at the same time serve to show the student the relation between the theoretical principles involved and their practical application to actual problems. The various chapters cover the properties of water, steam, and air, the mechanics of their movement, heat transmission of building materials and of radiators, fuels and combustion, boilers, heating water in tanks and pools, chimneys, direct steam and hot-water heating, electrical heating, ventilation, warm-air furnaces, fan heating, air conditioning, temperature and humidity control, exhaust-steam heating, district heating, pipe fittings, valves, covering, the cost of equipment, and the preparation of plans and specifications.

While a great deal of information in the book is of value to the trained engineer, many of the rules given are so complex as to puzzle the average architect and the heating engineer without a thorough technical training. As a matter of fact, the work cannot help but impress one familiar with the subject that it will be of far more value in the classroom and in the hands of a technically trained engineer with the patience to digest the information contained in it, than it will be to the heating engineer that has graduated from the bench, and even the technically trained engineer seeking formulæ for his work that may be easily understood and easily applied. A great deal of the matter in the book has been taken from other sources. Much of the matter so obtained could have been omitted to advantage. In fact, one might well question the advisability of encumbering the book with tables of valve and pipe-fitting dimensions and the various dimensions of proprietary articles. As this information can be obtained from catalogues obtainable for the asking, it hardly seems fair for the purchaser of the work to pay for so much information that could be obtained elsewhere without cost. Again, there is a complete chapter on fuels and combustion. It would seem preferable to present instead a brief summary of the essential data required by the heating engineer and refer him for further information to the many excellent treatments of this subject in other books. In many cases a number of rules proposed

by different authors for solving the same problem are given, and it is to be regretted that their advantages and disadvantages and their limitations are not commented upon by the authors, for their presentation without such comment leads to perplexity in the mind of users of the book. The selection of rules given might here and there be improved. For instance, one finds no reference to the data on heat transmission through building substances, and to the rules for determining radiating surfaces as used by the late Alfred R. Wolff. When one considers the effect these data had on the science of heating in the United States, their omission in a work of this magnitude is to be regretted. This criticism should not obscure the fact that the work contains a great deal of very useful information, a most excellent and lavish selection of illustrations, and a good deal of matter that cannot be found in other works on the subject.

A Member.

To the Editor:

The authors believe, in common with many other engineers, that the subject of heating and ventilation is of such commercial importance that a somewhat more comprehensive treatment is warranted than has thus far appeared.

This volume is now in use in many engineering offices, and from the reports the publishers and authors have received the method of treatment employed has apparently been justified.

The work is distinctly not a set of "Rules," and we are inclined to agree with the reviewer that the book was written for the man of technical training, or one who is acquiring such a training. Engineering subjects fortunately, perhaps, require some study to grasp, and this branch of engineering apparently is no exception to the rule.

Engineers in general, we believe, prefer to have the derivation of the formulæ and constants used stated in the text, rather than the bare statement of rules or formulæ. For this reason we have included such matter as our experiments on the heat transmission of building construction, which we believe are more complete, in many respects, than any heretofore published data in this connection.

The section devoted to hot-blast heating can hardly be reduced if one is to cover the subject properly.

Particular attention is directed to fan testing and the application of fan tables—a subject that comparatively few engineers are familiar with. This is the first treatise on the subject to include complete data on air washing and humidification, as well as a number of other subdivisions of heating.

The Authors.

Elementary Course in Lagrange's Equations. B. N. W[illegible], Mechanical Engineer. Philadelphia Book Co. [illegible] Cloth, 6x9 in., 195 pp., 58 illustrations. [illegible]

In the preparation of this book the [illegible] to present the methods of analysis of Lag[illegible] that the average engineer might have a[illegible] for the formulation of the fundamental pro[illegible] arising in engineering practice. It is there[illegible] condensed selection of fundamental equati[illegible] developed from foundational principles, an[illegible] the methods of the calculus and a ready inte[illegible]lic notation are essential to its reading.

The work is divided into [illegible] which treat of the following subjects: Synopsis of principles of dynamics, 85 pp.; Lagrange's equations for a particle, 27 pp.; Lagrange's equations for a system, 31 pp.; Lagrange's equations for relative motion, 16 pp.; small oscillations, 35 pp. The method of treatment is quite similar to that found in the usual mathematical texts of this sort, in that the bases for the derivation of the several formulated relationships arrived at are certain general and fundamental concepts symbolically expressed, and the usual applications of the laws of numbers are resorted to in their treatment and transformation.

Aside from the references to the embodiment of certain dynamic problems in the case of the gyroscope, the automobile, and the balancing machine devised by the author, there are hardly any references to engineering practice illustrative of the problems dealt with. The treatment of the subject may therefore be characterized as academic. It would appear therefore that the main purpose of the book—to promote a use of Lagrange's method in the solution of dynamic problems—has been defeated. There never has been any lack of material of the sort this book contains. The difficulty does not seem to lie in this direction. Since the capacity to recognize in engineering problems certain fundamental principles needs more cultivation than the faculty of dealing with laws of numbers, it appears that the value of the book would have been enhanced for the engineer if more attention had been given to engineering problems. It is a simple matter for the student to learn that, given a beam of certain material, proportions, loading and methods of support, the moments and stresses arising are found "thus" and the relations are formulated "so." But one able to solve this sort of a problem is wholly at sea if given a machine and told to determine the nature and magnitude of the loadings of certain members, the rigidity of their support, the probability of maximum stress, where found and how much. This latter sort of text writing is rare and is very much needed.

The value of the book would be very much increased if there were a number of engineering applications given to illustrate the different problems. As it is, the engineer reading the book will naturally ask himself the question, "If this sort of analysis is so valuable for the solution of dynamic problems arising in engineering practice, why are there not some engineering problems given in illustration?" It is hoped that in future editions the author will more intimately associate the purely mathematical with the engineering problem, and thus show engineers how this work of Lagrange may be used to a greater extent than it is today.

The book is well bound and neatly printed on good paper. The figures are clear and neatly made.

Walter Rautenstrauch.

Fatigue Study. The Elimination of Humanity's Greatest Waste. A First Step in Motion Study. By Frank B. Gilbreth, Mem.Am.Soc. M.E. and Lillian M. Gilbreth, Ph.D. Sturgis & Walton Company, New York, 1916. Cloth, 5x7½ in., 159 pp., 33 illustrations. $1.50.

This little book should be read by the president and directors of every industrial corporation, and copies of it should be presented to the superintendent of each department, with instructions to read it and then hand it to the foremen. A copy of it should be in every works library. "It is a good thing, pass it along." "Safety first" is the motto of every well-conducted factory: "fatigue study next" should be added to it.

Fatigue, the authors say, is a necessary by-product of activity. A little fatigue is easily overcome if proper rest is supplied immediately. Twice the amount of fatigue requires more than twice the amount of rest. Excessive fatigue requires a rest period that might have to be prolonged indefinitely. It is this fact that lies at the basis of the great unnecessary

[illegible] accumulated fatigue. Fatigue study is an attack upon unnecessary waste. It aims: 1 To determine accurately what fatigue results from doing various types of work; 2 To eliminate all unnecessary fatigue; 3 To reduce the necessary fatigue to the lowest amount possible; 4 To provide all possible means for overcoming fatigue; 5 To put the facts obtained from the study into such form that every worker can use them for himself to get more out of life.

This book will outline a method of attack and furnish a working [illegible] for attacking the fatigue problem in an [illegible] place. What *has* been done is worth while when we know [illegible] has been done, and *why* it has been done." The authors discuss, in simple language that a child can understand, the what, the how, and the why of fatigue study and fatigue elimination. Fatigue elimination in a factory serves a double purpose. It makes money for the owner, by decreasing the waste of time which is caused by unnecessary fatigue, and increases the number of "happiness minutes" of the worker, and in order to begin fatigue study and fatigue elimination the best thing to do is to get the ideas that are so ably expressed in Mr. and Mrs. Gilbreth's little book. For those readers of the book who are not personally acquainted with Mr. Gilbreth, it may be well to state, what is not stated in the book, that the picture of the man in shirtsleeves examining the micro-motion film, is an excellent photograph of Mr. Gilbreth himself in one of his characteristic attitudes.

WM. KENT.

Oxy-Acetylene Welding. By C. W. Miller. The Industrial Press, New York, 1916. Cloth, 6x9 in., 287 pp., 192 illustrations. $2.50.

During the little more than ten years that oxy-acetylene welding and cutting of metals have been attaining importance as commercial industrial processes, considerable has been published concerning them. It has taken the form, however, for the most part of separate articles in the technical papers bearing on specific pieces of work that have been accomplished, or of the special forms of apparatus that have been developed from time to time for doing the work. The few books that have appeared have been rather limited in their scope as a rule or else lacking in detail when they attempted to cover the whole broad field.

The publisher of *Machinery* felt therefore that there was room for a comprehensive book on the art—entitled to a place in its Mechanical Library—and in compiling this Vol. XII of that series has supplemented what the author prepared with text and illustrations taken from miscellaneous articles previously printed in *Machinery*.

Mainly the purpose has been to make the work of practical utility to prospective users of the welding and cutting torches, and to that end highly scientific and technical treatment of the subject has been avoided. This intention appears to have been consistently adhered to, while at the same time enough has been included relative to the principles involved so that an intelligent understanding may be had of the functions of the apparatus and how to use it successfully.

As would be expected, the forepart of the book is elementary, describing the construction of the torches and the means for producing and storing the gases used. Then comes an account of the accessories desirable in a shop equipped for handling repair work, for this use of the process, rather than its application in manufacturing, comes more within the experience of the author. In fact, it would be difficult within the covers of any one book to deal adequately with manufacturing uses, since they are always more or less special and necessarily developed experimentally, hence no individual would be competent to discuss more than a limited field of such applications. If this were not so obvious it would be more an occasion of criticism that the title of the book does not indicate that it is practically confined to repair work.

One chapter embraces the contents thus far specifically alluded to, and the next nine deal with repair welding. A supplementary chapter describes the lead-burning process which, though much older and more familiar, is, after all, the original fusion-welding process; and finally, the last chapter takes up that distinctly different use of the oxy-acetylene torch, the cutting of metals by an oxygen jet actually burning its way through.

The section on repair work is the most valuable part so far as practical usefulness is concerned. It begins with the preparation of the work, which, being so essential to successful results, would have been better were it more fully treated. Expansion and contraction effects are referred to and directions given to allow for them in a few specific jobs, but since it is a lack of understanding the underlying principles of these effects and anticipating them with proper provisions that accounts for most of the failures in welded repairs, it would have added value to the book had there been a few well-chosen typical examples with illustrations explaining the fundamental principles of contraction in cooling. Knowing the whys and wherefores and when to look out for them, the reader could be put in position to work out his own problems as to the proper handling of almost any casting that he might be called upon to repair. It is a knowledge of just this element that makes the difference between a good and a poor welder.

On the matters of materials and fluxes and the obtaining of a properly adjusted neutral flame the discussion is excellent. The chapter on cast-iron welding which follows is also very commendable. It is one of the longest in the book, and justifiably so, for it deals with the most common class of repairs. Steel, malleable iron, copper, and copper alloys are metals less frequently welded, and one chapter suffices to cover the special precautions needful. Another whole chapter deals with that most difficult of metals, aluminum, and its extensive use in automobile parts makes skill in its repair a worth-while accomplishment.

Sheet-metal and plate welding, as of boilers, tanks, tubes, etc., is the nearest approach to manufacturing uses referred to and is sufficiently treated, considering the avowed scope of the book. Boiler welding is as yet not accepted as safe enough. State laws, insurance companies, and the A. S. M. E. Boiler Code forbid it. Probably it will not be countenanced until some trustworthy means is discovered for proving the integrity of a weld without testing it to destruction, when it is too late to put it in service, and we cannot be sure of duplicating results with what appear to be identical conditions. Tank welding, however, is usually permissible.

Some very useful general considerations are given in the last chapter of this section. They include such important subjects as unusual difficulties, qualifications and training of welders, care of apparatus, overhead costs, commercial limitations of the welding process, safety precautions in the use of apparatus, and other things that should be brought to the attention of the beginner to guard him against the pitfalls. A more than usually complete index is especially valuable in guiding the reader to those parts of the section on repair work where he will find the information needed for work in hand.

Assuredly, there is a field for such a book as this, and while it may not be perfect, nothing better of its kind has yet been brought out to the best knowledge of the reviewer.

HENRY R. COBLEIGH.

General Information Regarding Presentation of Papers

THE American Society of Mechanical Engineers solicits original papers upon subjects of mechanical-engineering interest for presentation and discussion at its forthcoming Annual Meeting to be held in New York City, December, 1917, and also at its Spring Meeting to be held in Worcester, Mass., May, 1918. The manuscripts of such papers should be submitted to the Secretary, 29 West 39th Street, New York City, who will refer them to the Committee on Meetings for consideration.

Papers for presentation and discussion at meetings of Sections of the Society, which are organized in 21 cities throughout the country and which hold meetings monthly from September to May, are also solicited by the Society. Correspondence regarding Sections papers should be addressed to the respective Sections chairmen as follows:

Atlanta, Ga.	Earl F. Scott, 707 Candler Building
Baltimore, Md.	C. C. Thomas, Johns Hopkins University
Birmingham, Ala.	Roy E. Brakeman, P. O. Box 297
Boston, Mass.	A. L. Williston, 27 Kilsyth Rd., Brookline
Buffalo, N. Y.	John Younger, 1695 Elmwood Ave.
Chicago, Ill.	Joseph Harrington, Riverside, Ill.
Cincinnati, O	F. A. Geier, Cincinnati Milling Machine Co.
Detroit, Mich	M. E. Cooley, Univ. of Michigan
Erie, Pa	J. F. Wadsworth, 310 Commerce Building
Indianapolis, Ind.	W. H. Insley, Insley Manufacturing Company
Los Angeles, Cal.	W. A. E. Noble, 5419 Russell Ave.
Minnesota	J. V. Martenis, Univ. of Minnesota, Minneapolis
Milwaukee, Wis.	E. Hutchens, 866 Superior St.
New Haven, Conn.	H. B. Sargent, 247 Church St.
New Orleans, La	W. B. Gregory, Tulane University
New York, N. Y.	H. R. Cobleigh, 29 West 39th St.
Philadelphia, Pa	E. B. Carter, Midvale Steel Co.
Providence, R. I.	J. A. Brooks, Brown University
San Francisco, Cal.	F. W. Gay, 310 Sansome St.
St. Louis, Mo.	H. R. Setz, 5651 Maple Ave.
Worcester, Mass.	Paul B. Morgan, 15 Belmont St.

All papers accepted for a general meeting are printed in pamphlet form in advance of the meeting and are available to the membership of the Society. Also, comprehensive abstracts of the papers are printed in the monthly Journal in advance of the meeting.

After presentation and discussion, the revised papers are printed in The Transactions of The American Society of Mechanical Engineers, issued annually.

All papers presented at Section meetings are considered by the Publication Committee for publication in The Journal. The most meritorious Section papers are also assigned to general meetings and may be printed in The Transactions.

Authors of accepted papers receive twenty specially-bound copies with the compliments of the Society. Arrangements for the purchase of reprints at nominal price both from The Journal, size 9 in. x 12 in., and from The Transactions, size 6 in. x 9 in., can also be made through the Secretary.

OIL BURNING

Some Practical Details of Burning Oil Under Boilers to Produce Steam, with Particular Reference to Stationary Boilers, with Discussion

By B. S. NELSON, NEW ORLEANS, LA

Member of the Society

THE subject of oil burning should be particularly interesting to engineers in the South because Louisiana can take credit for originating the widespread commercial use of oil as fuel in the United States. While a great deal of oil was produced in Pennsylvania fields and some of it was utilized for fuel purposes before the discovery of oil here, the Pennsylvania oils were of such high grade as to make them more valuable when refined into illuminating and lubricating oils than as fuel. In fact, it has been stated that for a considerable time oil companies in Pennsylvania burned coal under their boilers.

With the discovery of Spindle Top in 1901 and the rapid development of the California fields, the supply of crude oil became greater than the demand for refined products; hence the use of oil as fuel. The recent development of the Mexican oil fields has given the South an additional supply of oil to draw on as fuel.

Fuel oil is oil which is more valuable to the producer as fuel than as a refined product. Due to the rapid increase in use of gasoline in motor vehicles and the use of distillates in stationary engines, and also to the improvements in refining crude oils, it is probable that very little crude oil will be used for fuel, and that the fuel most used will be some sort of residuum or scalped oils; that is, the oil from which the lighter constituents have been distilled off. Though the Mexican oils are, as a rule, heavier and contain less of the lighter constituents than American oils, even they are now being distilled and the residue used as fuel. The result of this will be that more attention will have to be paid to the oil-burning system than was necessary with the lighter crude oils used heretofore, because a scalped oil is heavier and more viscous than crude oil. One advantage in using a scalped oil is that there is less fire risk, because its flash point is higher than the flash point of the crude oil.

Fuel oils may be classified according to several of their characteristics, which are more or less dependent upon each other. Some of these are the flash point, or temperature at which an oil will give off inflammable vapors; the viscosity, which may be explained as the molecular friction; the specific gravity; the heat value, and the sulphur content.

The flash point of an oil is of interest particularly from the standpoint of safety. On land installations, where the oil is usually buried in a closed tank, the flash point is of less importance than on shipboard, where inflammable vapors are apt to accumulate in the hull or to be freed in a closed boiler room, due to leaky piping.

The viscosity of an oil is the principal consideration in the actual burning of that oil, because the success of the burner or atomizer depends largely on its ability to atomize the fuel into sufficiently fine particles to insure satisfactory combustion, and the more viscous the oil the more difficult this atomization. There are various methods of expressing the viscosity, one of the most used being in terms of the Engler scale. Degrees Engler means simply the ratio of the time it takes a given quantity of an oil to flow through a standard orifice as compared to the time it would take the same volume of water to flow through. Oil is usually sold, however, on the basis of its specific gravity (generally measured in degrees Baumé) and its heat value and moisture content. It is usually assumed that the heavier an oil in degrees Baumé, the more viscous is that oil, but this is not always strictly true.

Through the courtesy of E. H. Peabody, Mem.Am.Soc.M.E., in Fig. 1 is reproduced a very interesting chart giving the characteristics of some thirty different oils. This chart gives the temperature-viscosity diagram of these fuels, the specific gravity, the degrees Baumé and the flash point. Comparing two crude oils from these curves brings out the relation, or rather lack of relation, between degrees Baumé and degrees Engler:

	Deg. B.	Flash Pt.	Deg. Eng. at 230 Deg. Fahr.
Panuca Crude..........	13.7	140	13.75
No. 18 California.......	12.7	285	5.2

It is to be regretted that oil is not specified in terms of specific gravity instead of degrees Baumé, because in any calculations involving the weight of the oil per gallon or per barrel it is necessary to refer back to specific gravity. Further, the heaviest oil that can be designated on the Baumé scale for liquids lighter than water is 10 deg. B., or unit specific gravity. There are oils being used now of 10 and 12 deg. B., and no doubt still heavier oils will be used, which will call for two different Baumé scales and cause confusion.

Spindle Top oil has a specific gravity of about 0.92, corresponding to 22 deg. B., and its heat value averages about 19,700 B.t.u. California oil is somewhat heavier, the average grade of that oil having a specific gravity of about 0.95, or 18 deg. B., heat value about 18,500 B.t.u. The Mexican oils vary considerably in specific gravity and heat value, but as a rule they are much heavier than either the California or Texas oils; a typical oil now used has 0.99 sp. gr., or 12 deg. B., with a heat value of about 18,200 B.t.u.

Table 1 compares the prices of coal and oil, taking as a basis coal of the quality of Pratt, Alabama, and Pittsburgh coal, sold in the New Orleans market. While with these coals an evaporation of 10 lb. from and at 212 deg. can be realized with well-designed water-tube boilers when the boilers have ample heating surface and are in the hands of skillful firemen, it is extremely doubtful if any boilers in regular service are showing better than 8 lb., and the great majority are below this figure. Therefore, if we take 8 lb. as a basis, we are giving the coal its full value. Now, with oil giving 19,500 B.t.u. per lb., an evaporation of 14.5 lb. should be readily obtained if the apparatus for supplying the oil to the furnaces is of first-class design and if the furnaces are properly arranged. With this ratio as a basis, it is apparent that a pound of coal is equivalent to 8/14.5 or 0.541 lb. of oil. A barrel of crude

Presented at a joint meeting of the Louisiana Association of Members of the American Society of Civil Engineers and the New Orleans Section of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, January 22, 1917.

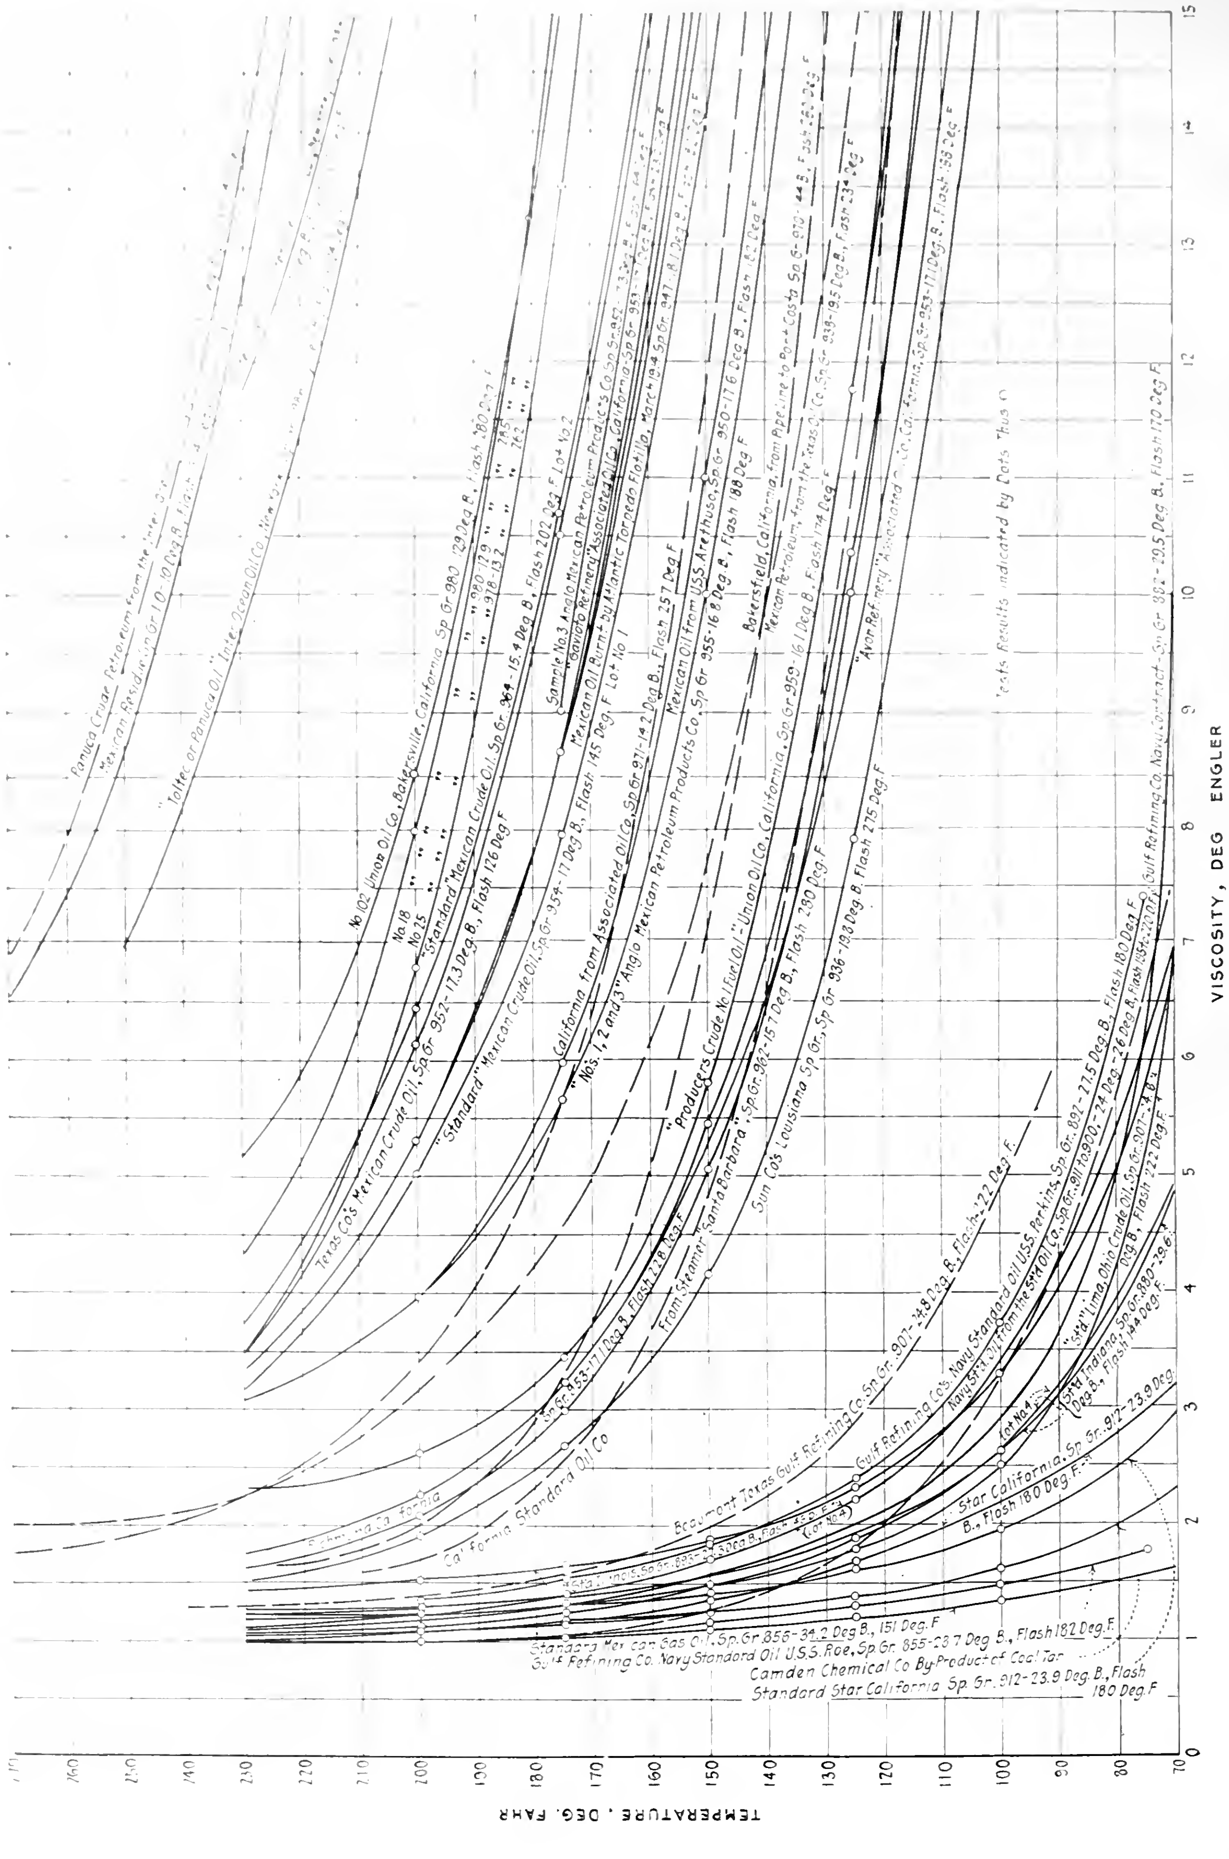

Fig. 1 Temperature-Viscosity Diagram of Fuel Oils

Reproduced from Curves of Lieut.-Comm. John J. Hyland, U.S.N., with additions (shown in dotted lines) by E. H. Peabody, Mem. Am. Soc. M. E.

oil weighs approximately 325 lb., therefore one ton (2000 lb.) of coal is equivalent in practical heating value to 3.34 bbl. of oil.

TABLE I COMPARISON OF PRICES OF COAL AND OIL

Coal. Dollars per Ton, 2000 lb.	Oil, Dollars per Bbl.	
5.00	1.50	[illegible]
4.75	[illegible]	[illegible]
4.50	[illegible]	[illegible]
4.25	1.28	[illegible]
4.00	1.20	
3.75	[illegible]	[illegible]
3.50	1.07	[illegible]
3.25	98	
3.00	90	[illegible]
2.75	[illegible]	[illegible]
2.50	[illegible]	[illegible]
2.25	68	[illegible]
2.00	60	[illegible]

[1] Not allowing for labor saving.
[2] Assuming 10 per cent of cost of fuel in labor of firing and handling ashes saved by using oil, a conservative estimate for plants of over 300 hp.

An interesting point to note with reference to the heat value of an oil is that the B.t.u. usually given is the high heat value or heat value determined in a bomb calorimeter. The actual heat value available in a boiler furnace is less because all fuel oil contains a considerable percentage of hydrogen, and the latent heat of the steam formed by the combustion of this hydrogen passes up the stack as waste heat.

In all the heavier grades of fuel, particularly the Mexican oils, water mixed with the oil is in the form of an emulsion and will not settle out in a tank as it will with the lighter American crudes. This is not so much a disadvantage as it would seem, other than causing a lowering of the heat value. With an oil light enough for the water to settle out of its own accord, this water will frequently accumulate in the tank and piping and go over into the burners in a slug, putting the burners out; but with heavy oil a very considerable amount of water can go through the burner with no bad effect. The writer is inclined to believe that a small quantity of water in heavy oil is an advantage in that these oils are usually heated above the boiling point of water to effect atomization, and the vaporizing of the moisture in the oil as it leaves the burner tip probably helps to atomize the oil more thoroughly.

Oil has numerous other advantages over coal than cost of fuel. The storage space required is much less for an equal number of heat units: there are no ashes to be disposed of; less boiler-room help is required for firing; the wear and tear on the furnace lining is smaller because the firedoors do not have to be opened, with the consequent chilling of the brickwork. Very little repairs are necessary to the grate bars; a much smaller stack can be used for the same boiler horsepower; the boiler can be forced with natural draft considerably beyond what it can with coal, an important feature where boiler capacity is scant; where feedwater is bad it is often possible to carry a load with two oil-fired boilers which would require three boilers were coal used, thus allowing the cleaning and repairing of one dirty boiler at a time. Steam can be raised much more quickly and with no loss due to banking fires. It takes about 10 per cent of the fuel normally consumed by a boiler at rated load to keep its fire banked with coal. In case of an emergency the fire can be instantly extinguished: any one who has had to draw a hot coal fire in an emergency can appreciate this particular advantage.

THE SUCCESSFUL OIL-BURNING INSTALLATION

There are several factors entering into the successful oil-burning installation, some of which affect the reliability of the system and others its efficient operation.

The first consideration for reliability is the oil supply to the burners, involving the storage tanks, pumping outfit, and heaters. The size of a storage tank varies, of course, with the size of the boiler plant, but it should be large enough, at least, to hold a carload of oil. A very popular size of tank is a 10,000-gal. tank, which is about 8 ft. in diameter and about 30 ft. long. These tanks are usually built of ¼ in. steel with ⅜ in. heads, though if the tank is subject to corrosion from the outside it should be made of heavier material. The tank should be equipped with a manhole and filling pipe, a suction opening, a vent opening, and openings for steam heating coil connections. The insurance requirements call for the tank to be below the level of the pumps and burners, which means that it is usually buried in the ground. The tank should be preferably not less than 50 ft. from the nearest building.

The oil pumps are the next consideration. The pump that has given the best results is a duplex steam pump, piston-pattern type, with brass valves, metallic packing in the oil piston and special gaskets and piston-rod packing. The size of pump should be based on a very low piston speed.

The pump should be fitted with an air chamber on the discharge side to steady its pulsations of pressure, and a governor on the steam end to maintain the pressure constant. The pressure at which the oil is delivered to the burners depends largely on the character of the oil, varying from 40 lb. for oil of 26 to 30 deg. B. to 80 lb. for oil of 12 deg. B. The pump should also be equipped with strainers on the suction side to keep trash from getting under the pump valves. Duplicate pumps should always be installed, so that if anything goes wrong with one pump the other may be put in service without shutting down the plant.

The pump should be set as near the level of the oil as possible to give the minimum suction lift, and the suction pipe should be as straight as possible, preferably with bends instead of elbows. Where the suction pipe is long, a foot valve at the bottom of the suction line in the tank is desirable. This should be a valve without leather seats, as fuel oil deteriorates leather. A very good valve to use is a horizontal-swing check used in a vertical position. In addition to air chamber and governor, the pump should be equipped with a relief valve set at a pressure heavier than the working pressure, so as to minimize the danger of breaking the pump. This relief valve should be of the enclosed type, so that its overflow can be piped back to the tank.

The heavier oils require heating in the suction tank in order to enable the pump to lift them. The temperature must not be high enough to cause the oil to vaporize under the suction pull of the pump. The writer has found a temperature of 110 to 130 deg. about right for Mexican oil of 12 to 18 deg. B. According to Commander John J. Hyland, U.S.N. (*Jour. A. S. N. E.*, May 1914), the viscosity of the oil had to be reduced to 375 deg. Eng. in order to obtain full capacity from a Blake pump. In order to gage this temperature accurately, a thermometer should be installed in the suction line near the pump. If this suction line is long, or has several elbows in it, it should be made one or two sizes larger than the suction opening of the pump.

The next question is that of the heater. Practically all the oil now burned as fuel requires heating in order to reduce its viscosity and facilitate atomization at the burner. There is a wide choice of heaters, but the principal considerations are,

first, to have the heater of ample heating surface, and second, to be sure that this heating surface is all utilized. In heating oil with a steam coil in a vessel of oil there is a tendency to local heating, that is, the oil next to the coils may be very warm, but this heat is not readily transmitted to the adjacent oil, so that a heater in which the oil is kept in rapid motion over all the heating surface in the coil is apt to give best results. In one type of heater the oil is sent at high velocity through a long coil of brass pipe heated by steam on the outside.

There are several pumping sets on the market which combine all the requisites enumerated above in one self-contained unit. Fig. 2 shows such an outfit which, it will be noted, consists of duplicate pumps with pressure governor, air chamber, gage, suction strainers on pumps, relief valve and heater.

The temperature to which the oil must be heated naturally varies with its viscosity. For fuel oil usually burned in the South, a temperature from 180 to 220 deg. is satisfactory, the higher temperature being for oil of 12 deg. B. As far as we know, no experiments have been made to determine the degrees Engler to which oil must be heated, but judging from our experience and with the aid of the temperature-viscosity diagrams, we should say that about 8 to 9 deg. Eng. is the viscosity required for a steam-atomizer burner. It has been stated, however, that any oil which can be pumped readily can be atomized by a steam atomizer. After the oil is heated at the pump (and its temperature should be read by a thermometer permanently fixed in the discharge line from the pumps), care should be taken to keep the oil hot until it reaches the burner by proper covering of the pipes. When the discharge line is very long or the oil pump is a considerable distance from the burners, a very helpful device is to run a small live-steam pipe inside the oil-discharge pipe. When this is done, a stuffing box should be placed at one end of the steam pipe to take care of expansion, which will be greater on the steam than on the oil pipe.

In an installation where the burners are shut down for any length of time, a bypass should always be provided from the farthest end of the oil supply to the burners back to the pump suction, or preferably to the tank. The function of this is to be able to fill the oil header with heated oil before attempting to light the burners. With much of the heavy oil now used, it will be found impossible to even light the burner until hot oil reaches the burner tip. If the above bypass is not used, there will be considerable messing up of the furnace and ashpit with unburned oil.

More stress has probably been laid on the oil burner than on any other part of the installation, which has led to the belief on the part of people unfamiliar with the burning of oil that the burner is the whole thing, whereas, as a matter of fact, the burner contributes but a very small part to the success of the installation. The term *burner* is really a misnomer, because the only function the burner performs is to atomize the fuel into sufficiently fine particles to effect complete combustion in the furnace.

For land installations, the type of burner which has proved best is the steam-atomizer burner with oil supplied to it under pressure. The essentials of such a burner are simplicity, cheaply renewable wearing parts, economy in steam for atomizing, and the production of a flame of such shape that makes good combustion and, hence, high boiler efficiency possible. The burners may be of either the round-flame or flat-flame type. The flat-flame type is preferable because it uses less steam for atomizing and produces a flame of such shape as to permit proper mixture of air to support combustion without excess air, which is not the case with a round-flame burner.

The use of a target wall is not necessary and may cause injury to the heating surface of the boiler by causing the flame to concentrate on a small portion of the surface, resulting in what is termed "blowpipe" action.

The general type of flat-flame burner is a tip in which are two narrow parallel and horizontal slots, the oil flowing out of the upper slot in fan shape on to the fan-shaped jet of steam issuing from the lower slot.

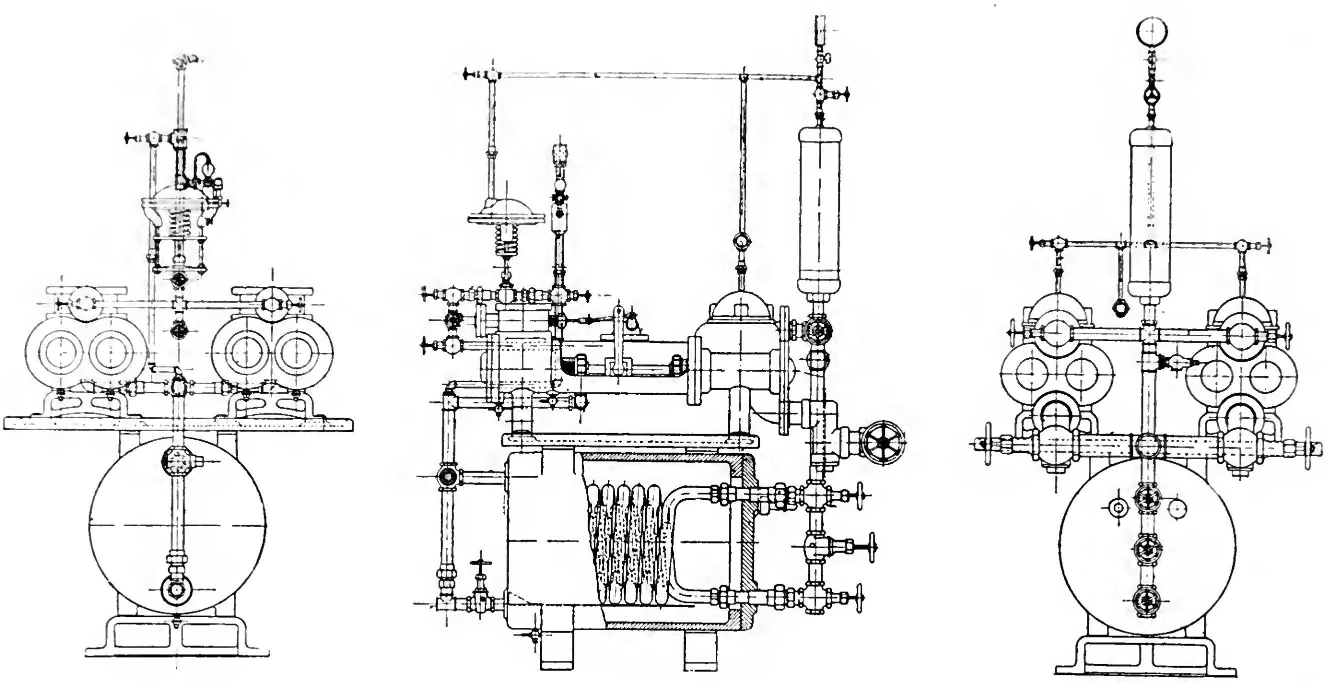

Fig. 2 Oil-Pumping Set, Showing Duplicate Pumps with Pressure Governor, Air Chamber, Gage, Suction Strainers, Relief Valve and Heater

The position of the burner depends largely on the type of boiler. For a boiler with a long unobstructed furnace, such as a horizontal return tubular, or a boiler of the Heine or Erie City type, a burner set in the firing door is very satisfactory. For boilers where the furnace is short and the travel of the gases is upward, such as in the Babcock & Wilcox or Stirling boiler, the best arrangement is to put the burner at the back, shooting toward the front of the boiler. In either case air should be admitted to the furnace through a checkerwork of firebrick laid on the grate bars. The shape of this checker work should approximate the shape of the flame and thus reduce excess air, and the area of all the holes should be equal to 4 sq. in. per boiler horsepower.

Steam and oil connections to a burner should be made to allow for the expansion and contraction of the oil and the steam headers, and should have unions above and below the burner to enable the latter to be taken out quickly for cleaning. A very essential point in installing a burner is to see that it gets dry steam. The simplest way to do this is to take the steam from the top of the auxiliary steam header. A steam connection should be provided on each burner for blowing the oil out of the burner when it is shut down, as otherwise this oil will carbonize, due to the heat radiated from the hot furnace.

The principal consideration affecting the efficiency of an oil-burner installation, other than the choice of a burner economical in the use of steam (and giving the proper shape of flame), is the proper control of the air supply. One of the advantages of burning oil, mentioned above, was the possibility of reducing the excess air to effect combustion. Conversely, one of the principal losses is the ease with which excess air can be admitted. For any particular installation (assuming the setting is tight and checkerwork properly arranged), the best draft should be determined by installing a draft gage on each boiler connected to the furnace, then gradually closing the damper until there appears just a faint trace of black smoke at the stack, and finally maintaining the draft at that point. It should be noted, however, that there can easily be smoke with excess air for two reasons, first, if the checkerwork is not properly arranged in the furnace there will be excess air, even though the combustion be incomplete, and second, poor atomization of the oil at the burner will give a grayish-white smoke, which is often mistaken for insufficient air. A more accurate method of gaging the air supply is to make periodical analyses of the stack gases and keep a record of the stack temperatures. The stack gases should not be over 100 deg. hotter than the steam, and no difficulty should be experienced in getting 13 to 14 per cent CO_2 in regular operation.

DISCUSSION

MR. SNYPP GIVES THE REQUIREMENTS FOR SUCCESSFULLY FIRING HEAVY CRUDES

Charles E. Snypp spoke of the difficulties experienced in handling and firing heavy Mexican crude oils. He recited an experience in which these heavy crude oils were substituted for the lighter crude oils, such as Spindle Top, Beaumont and Louisiana oils, in a plant especially adapted to the burning of lighter grades. Fortunately for the continuous working of the plant, the change came about gradually over a period of a couple of years, and thus the machinery was corrected and adapted from time to time to the heavy grades.

Owing to the rigid insurance requirements, the supply tank was located about 400 ft. distant from the boilers, and about 2 ft. beneath the level of the burners. This tank was buried and dirt arched over the top to supply the necessary weight to overcome its buoyancy when empty, as the ground was more or less saturated with water.

The pump which supplied the burners was located in the boiler room, and light crude of 22 deg. B. could be easily drawn through a 1½-in. pipe by pump suction without heating. For heavy crudes a 3-in. pipe was substituted and a large-capacity, slow-motion pump was used. This would handle medium grades, but in cold or wet weather the arrangement was too delicate to be relied upon. A booster pump was then located at the tank, and oil was heated to 130 deg. fahr. and forced through this 3-in. pipe. This relayed the oil to the burners. A 2-in. overflow pipe was laid from the pump, located in the fireroom, to a return pipe to the ground tanks. This slow-motion pump was speeded by allowing oil to flow freely through a ½-in. vent pipe located in the top of the pump chamber and controlled by a gate valve, and this oil circulated through the 2-in. pipe to the ground tank. This proved to be a very satisfactory arrangement for handling Mexican crudes.

Mexican crudes of 12 to 13 deg. B. should be heated to 120 to 130 deg. fahr. and delivered to the burners just under the distilling temperature, which is about 250 deg. fahr.

Superheated steam was found to be beneficial in atomizing this oil and delivering it to the fires. (The speaker had no data on the amount of preheat used, but believed that the oil should be delivered in a gaseous state to the fires.)

A 3-in. closed tube about 8 ft. long was located in the bottom of the firebox between two burners, and protected with one thickness of firebrick. Steam from the boilers was led through the front end of this tube through a ½-in. pipe, and the pipe extended to the rear end. A ¼-in. pipe was led from the steam space of this tube to the burners. The fuel oil was fed through a ¼-in. pipe into the rear end of a ¾-in. pipe which was inserted into this tube, extending the full length of the tube. Thus the oil was preheated by superheated steam and the superheated steam was used for atomizing.

The oil, flowing from the pump, located in the fireroom, was heated by the usual exhaust heater at the pump, then passed through a live-steam heater before entering the superheated tube.

The requirements for successfully firing heavy crude oils seem to be, first, large pipe lines and slow-moving, large-capacity pumps; and second, proper preheating; third, superheated steam to atomize the oil.

MR. BURWELL BRINGS OUT POINTS NEEDING SPECIAL ATTENTION IN OIL BURNING

Robert T. Burwell. Wherever any trouble with oil burning under boilers has occurred, it has generally been of a local nature, due to the impinging of the flame on some portion of the boiler, or to the scaling of the boiler, more than to anything else, and where the oil is properly distributed, we may expect as much life from the oil-fired as from the coal-fired boiler.

We thought when the Beaumont field was discovered that, inasmuch as this oil gave such a driving-hot fire—boilers could be forced so easily—the boiler would show defects much more quickly, but we have not met with anything of that kind in our experience. The railroads now drive their boilers rather hard, and yet they do not seem to have any such trouble. They have to be careful that the oil is well distributed so that the flame will not impinge against the tubes, and for that reason most of them place the burner at the front of the firebox so that the flame passes to the rear first.

As to the type of burner, Mr. Nelson has pointed out the

[illegible] advantages of the flat [illegible]; it has the additional advantage [illegible] flame against the boiler as is [illegible] burner [illegible] seems to distribute the fire [illegible] across the chamber. I am glad to see that they [illegible] away with the [illegible] which formerly caused us a great deal of annoyance because the flame would strike the [illegible] on one portion of the boiler [illegible] not exist in a coal fire.

[illegible] should bear in mind that they can [illegible] and in forcing it they should also [illegible] is forced, the more important it [illegible] good quality.

[illegible] Government Report on oil burning, one [illegible] the emphasis placed on the importance of having good men in charge of the burners. This factor does seem more important than in the case of burning coal, and yet we [illegible] that there is frequently considerable difference in efficiency of men firing coal.

An efficient fireman is very important to the economical operation of a plant. One of the best illustrations of the saving by a good fireman was shown in a test made at Milwaukee burning coal, where very accurate data were taken covering a period of twenty-four hours. This test was started at 9 a.m., when fireman *A* was on duty, and his showing at the end of five hours was 9.98 lb. of water per lb. of dry coal. Fireman *B* then came on and his watch lasted 8 hours, during which time the rate was 9.23 lb. At 10 p.m. fireman *C* came on for 8 hours, and showed exactly the same amount as *B*, namely, 9.23 lb. It was thought that the discrepancy was due to the boilers being cleaner during *A*'s watch, but he came on the next morning at six, and during the three hours to the end of the test made a showing of 9.87 lb. At the average price of coal this plant would save $2.40 per day by having firemen like *A* instead of *B* or *C*, and yet these three firemen were supposed to be in the same class. It is quite probable that many of our plants which have to select practically a new crew every year, such as our sugarhouses, must suffer in economy from this source.

Mr. Nelson has also pointed out the importance of a proper distribution of the air and a regulation of the air to reduce the excess air to a minimum, to which we might pay more attention with a view to developing a system by which we can determine exactly what we are doing in a plant. Mr. C. R. Weymouth, in Vol. 30 of Trans.Am.Soc.M.E., gives a table showing the boiler efficiency corresponding to varying percentages of excess air.

Referring to burners, while it appears that it does not make much difference about the type of burner, yet the Government Report gives the results of a test of the Korting mechanical burner showing an evaporation of 16.13 lb. of water from and at 212 deg. fahr. The temperature of the oil at the burners was 162 deg. fahr. and its pressure was 105 lb. per sq. in.; the temperature of the air entering the furnace was 250 deg. on one side and 290 deg. on the other, and the temperature of the gases at the fan suction was 465 deg. This result (16.13 lb. water) is unusually high, and with a burner that uses neither air nor steam to atomize the oil. The oil under pressure is forced through screw threads to the nozzle, the orifice of which somewhat resembles an injector. Most authorities place a limit of 130 deg. fahr. to which the oil shall be heated, and yet in this test the oil was heated to 162 deg., giving the best results that I have been able to find.

One point not yet touched on is the importance of having ample room in the combustion chamber. As a matter of fact, I think a small Dutch oven would give better results. I recall a power plant in this city where the boilers equipped with Murphy stokers were fitted up some years ago to burn oil—simply by lining the bed of the stoker with brick the fire had a clear sweep to the combustion chamber beneath the boilers. It was apparently the most perfect fire I have ever seen.

The form of furnace undoubtedly has considerable effect upon the temperature of the fire; in the case of a fuel in which a considerable portion burns as a gas, if these gases come in contact with a cool surface such as the boiler, before combustion is complete, there is a corresponding loss. It requires a temperature of about 1500 deg. fahr. to burn carbon monoxide, and it would therefore seem desirable that the furnace be of such proportions as to keep the gases above this temperature until complete combustion is assured.

An interesting illustration of the effect of the temperature of the fire on the burning of a fuel is seen in the case of bagasse. Green cane contains about 76.5 per cent water, thus if 10,000 lb. of cane were dried and the water caught, we would have 7650 lb. of water. The dry matter will burn readily and produces sufficient heat to evaporate more than 7650 lb. of water per 10,000 lb. of cane. The reason green cane will not burn is because the water in contact with the combustible matter prevents the temperature from attaining a point necessary for combustion.

My observations indicate that there is a practical operating condition against the use of oil in a bagasse furnace; as a rule, the man in charge is too prone to wait until the blowing of the safety valves notifies him that it is time to shut off the burner, whereas in using coal he is not apt to add it any more frequently than the condition of the bagasse fire demands. I recall one house that burned coal with bagasse with good results, but reported unsatisfactory results with oil. Of course, this is a condition that can be improved by careful supervision; it emphasizes, however, the importance of capable men in charge of the burners.

Speaking of forcing boilers, the Government Report calls attention to the fact that a burner has a limit, and it is impossible to force a boiler with an insufficient number of burners. This suggests the idea that in many instances more burners might be used to advantage; a greater number might also permit a wider range of regulation.

PROFESSOR WILLIAMSON DISCUSSES THE HEATING OF THE OIL AND ALSO ITS ATOMIZATION BY AIR

PROFESSOR C. S. WILLIAMSON. I do not know much about tests on oil burning, but it stands to reason that provided you do not reduce the oil to the elemental condition, in which case carbon would be deposited, the more nearly broken the oil is, the greater the heat value obtained, for this reason: we are all perfectly familiar with the fact that if a certain product—take a chemical compound, for instance—requires so many heat units to decompose it, we have put in that many heat units before we begin to get back any heat units from its actual combustion. Oils should not be heated above their flash points nor to a temperature at which carbon is separated. This temperature depends upon the property of the particular oil undergoing use or test, and so the flash temperature will vary.

Another point is the free play of the flame. It might not be accurate to so designate it, but it often causes a loss to the boiler efficiency, for if you impinge the oil flame on the boiler, the oil will split and produce a tarry residuum which drops into the pit, thereby losing a portion of the oil, although getting the best heat value possible for the oil actually consumed. There is a certain point, which varies for different oils, at

which the separation will take place, but one would have to determine this point for each oil to tell at what temperature the oil can be most economically preheated. If then the oil is preheated too highly, causing separation at this point and, further, the flame is allowed to impinge against the boiler plate, we have the formation of a residuum at two places, one (the former) of which may clog the burner, and the other produce the tarry residue in the pit below the furnace. The temperature of the flame at the point of combustion is considerably above that of the boiler plate, which possibly does not exceed 300 deg. fahr. in most cases. Hence the boiler plate will act as a condenser to the tarry residue, which has a higher boiling point than the surface upon which it is formed, and the cause of inefficient burning may be this mechanical arrangement instead of the oil being low in heat units. There is a splitting point then for different oils, which varies as mentioned.

There is a method of atomization which has not been spoken of, but which also gives good results where the installation is large enough to warrant putting it in, and that is compressed air. If you do your atomizing with compressed air, you do away with the steam you have accounted for in the absorption of heat. So where the plant is large enough, this method can be worked very successfully. It is somewhat a question of the amount of water which you introduce, in case of steam, as pitted against the nominal amount of water introduced in the case of air; also of thoroughly mixing the oxygen with the particles of oil as they are atomized.

MR. LEBERMUTH DISCUSSES COMBINATION OIL AND BAGASSE FURNACES

C. D. LEBERMUTH.[1] Mr. Burwell has struck the keynote in bagasse burning when he mentioned getting rid of the water. Not only is the heat value per pound of bagasse raised with a reduction of water, but also the heat value per pound of fiber. This has been worked out theoretically and experimentally by Prof. E. W. Kerr, Mem.Am.Soc.M.E. In practice it has been equally well demonstrated, where factories have reduced the moisture from 52 to 56 per cent, the limits in ordinary Louisiana six-roller mill work down to 47 per cent, now obtained by the best nine-roller mill plants.

It has been shown that under normal Louisiana conditions, 75 per cent excess air is about the minimum practicable in order to keep fires burning, this excess air being necessary in order to dry the water out of the bagasse. It can readily be seen that with this as a minimum and with the ordinary operating condition being about 100 per cent excess, bagasse-furnace conditions are not at all suited for burning oil. In every case where these fuels have been tried together the results have been poor. At Meeker, built as recently as 1912, such combination furnaces could never keep up steam until they were changed and the oil and bagasse fired separately.

At the Gramercy Refinery, some years ago, they found that when they were grinding cane about 1000 tons a day, the fuel used in the refinery was practically the same as when they were not grinding. They felt that the bad influence of the bagasse on the oil-furnace conditions overbalanced all the fuel value that they got from the bagasse. Now that no grinding is done they have some well-perfected furnaces using oil which give them from 72 to 74 per cent total furnace and boiler efficiency right along, and I saw the results of a 72-hour test there, where they obtained a total furnace and boiler efficiency of 80.4 per cent with return tubular boilers. From any other source than their chief engineer, such a figure looks almost too good to accept on its face value. But as I received it I feel sure of its validity.

What is needed in the way of a combination furnace is one which will burn bagasse efficiently and permit of burning oil to run boilers full load, efficiency not counting in this case at all. For oil will only be used when the milling tandem is stopped, which occurs only at infrequent intervals. It is simply a matter of getting the same horsepower out of the bagasse boilers during these stops.

MR. HUTSON DISCUSSES THE HANDLING OF MEXICAN OIL

H. L. HUTSON. When the Mexican oil companies first sent men up here to sell their oil, they sent an engineer to give instructions as to how the people should arrange to handle it, and I remember that his instructions were about as follows: Where the consumer had a large tank near the river, as most sugarhouses have, and was in the habit of gravitating the oil from the storage tank to the suction tank, he told them that they must put in a large pipe between those two, and put a pump and boiler at the storage tank, with heating coils in the storage tank, and force that oil from the storage tank to the suction tank, as it would not flow by gravity in cold weather. He said also that they should provide compressed air from some source, and when they shut down, particularly in the winter, they must blow all the oil out of the pipe line with compressed air, because if it froze on a cold day they would not get it started again. That surprised me very much, and for the first time I appreciated that they were furnishing us a semi-solid instead of a real liquid fuel.

PROFESSOR GREGORY CONSIDERS STEAM ATOMIZATION MORE SATISFACTORY THAN AIR

W. B. GREGORY. Professor Williamson has suggested the use of compressed air as an atomizer. In the pumping plant of the Neches Canal, near Beaumont, Texas, they first used steam as an atomizer, and then later installed a Connersville blower and thoroughly tried out burners with air as an atomizer. Whether the work was handled with great skill and intelligence I do not know, but I do know that they abandoned the use of air after some months of trial, and have ever since used steam instead. I think that in general, and for stationary plants at least, steam has been found by experiment to be far more satisfactory than air.

MR. DUSENBURY ENDORSES OIL AS FUEL

ALBERT T. DUSENBURY.[1] Our plants are scattered about through the waterways of South Louisiana, and we can handle oil to much greater advantage than we can coal. For small pumping plants, if I order a carload of coal and take it to the plant, sometimes it will last a year or more, but the deterioration in the common line of coal is very great; whereas with a carload of oil, you put it in a tank and you may keep it indefinitely. For that reason alone, for our work, and also in getting fuel oil to the dredgeboats, it has been very convenient, and I would be willing to pay a considerable premium to get oil rather than coal for the purposes for which I have need of fuel.

THE AUTHOR GIVES HIS CLOSURE

B. S. NELSON. In regard to the handling of heavy fuels, it may be stated as a general rule that heavy oils have to be

[1] Lebermuth & Israel Planting Co., New Orleans, La.

[1] Louisiana Meadows Co., New Orleans, La.

heated every time they are moved through a pipe. Assuming the case of an ordinary plant which gets its oil in tank cars, if the plant is so located that the tank car reaches the plant within a day after it leaves the refinery, it will usually be found warm enough to run out by gravity, as the oil is well heated when it is put into the tank car. In case the oil is too cold to run out by gravity, every tank car is fitted with heating coils, and a steam connection should be provided at the unloading switch to connect to these coils. A ½-in. or ¾-in. steam line is usually ample to heat up the oil in the tank.

As to precautions to render storage of oil safe, most of the oil now burned is of such high flash point that there is very little danger of gas accumulating. The curves in Fig. 1 give the flash points of various oils. However, any one can find the information required on this point in a new book entitled Fire Prevention and Protection, Rules for the Safe Storage of Oil.[1] Aside from insurance requirements, it is well to always keep the oil tank closed and have a vent pipe extending up out of danger from sparks or matches. Where oil storage is particularly dangerous, as on shipboard or barges, it is well to provide the storage tank with a large live-steam smothering connection, the function of which is to cover the oil with steam and so exclude the air. The refineries which have in the past suffered large loss from lightning setting their tanks afire now use an ingenious method of extinguishing fire by the use of foam made by pumping simultaneously to the top of the tanks two liquids which, when mixed, produce a heavy foam, which blankets the surface of the oil, thus excluding the air and extinguishing the fire.

With reference to the burner mentioned by Mr. Burwell, one reason that type is not used more is because it operates on the mechanical-atomizer principle, and the characteristic of it is high oil temperature and high pressure. I have seen cases where oil was heated as high as 240 deg. and carried 240 lb. of pressure on it. It is used a good deal in the Navy, but the oil has to be heated to such a high temperature and carry such a high pressure that it makes it dangerous. The burner used is a round-flame burner, usually, and requires forced draft, though in the naval vessels they use forced draft in any case.

The mechanical burner has been tried in stationary furnaces. Mr. Lockett and I did a little work on a mechanical flat-flame burner, but we did not get very far. A burner of that kind would be a desirable thing. Most of the mechanical burners depend on centrifugal force, and the oil comes out at the end of the burner as a diverging radial spray, and it is thrown out in a mist, which means that you get a round flame.

The average amount of steam used by the burner, to atomize the oil, depends on a good many things, for instance, whether the boiler is being run at full capacity or at part capacity. For a good burner, working under favorable conditions, you should not use over 1½ to 2 per cent of the steam generated by the boiler to atomize the fuel. With a poor burner, you may use 8 or 10 per cent. I have heard of some using as high as 15 per cent. The highest I ever got on a burner was 7 or 8 per cent.

With regard to the quantity of air required in the burning of oil, we figure on about 250 cu. ft. to a pound of oil, allowing for excess.

The manganese ore used in this country in the manufacture of ferromanganese has been hitherto mainly secured from three principal sources: viz., Russia (southern), India (southern British), and Brazil (east central). For a large number of years these three countries have outranked all other producing countries in the output of manganese ores. For the five years preceding the European war, Russia produced annually about 844,000 long tons, India 694,000 long tons, and Brazil 200,000 long tons.

The history of the manufacture of ferromanganese in the United States dates from the outbreak of the European war, summer of 1914. It appears that in no other substance entering intimately into the manufacture of steel have the war and the conditions brought about thereby produced such a radical effect upon domestic production and demand as in ferromanganese. The war itself, and coincident industrial activities, showed clearly the dependence of American steel makers upon European sources to furnish an adequate supply of one of the most essential ingredients in steel-making processes. Nor was there any vital reason for this, other than the excuse that foreign ferromanganese was cheap and abundant and prior to 1914 there was no indication that the supply would ever be cut off. As in the dye industry, this indicates the alarming improvidence of American manufacturers. England and, in a lesser degree, Germany, who have furnished the greater part of the ferromanganese used in this country, have made the alloy from imported ores, coming from Russia, India, and Brazil. It appears, in the light of the developments of the past two years, that the manufacture of ferromanganese on a commercial scale has come to be an important domestic industry, but it will remain so only so long as we have an abundant supply of ores. The closer trade relations which have been secured with South American countries seem to indicate that the greater portion of our manganese ore will come from Brazil in the future.—*Journal of the Franklin Institute*, May, 1917.

Pres. George W. Dunham of the S.A.E. and his collaborators have presented arguments that it is entirely feasible through the proper use of tractors to furnish any quantity of small grains that may be required for the world's food supply. Even with the 35,000 tractors now available the production may be materially increased by furnishing operators and Government supervision of the use of the tractors.

The present manufacturing equipment of the country is capable of producing at least 75,000 tractors a year under Government aid, and these additional tractors are estimated to be capable of cultivating in one year sufficient land to produce 1,000,000,000 bushels of small grain.

As regards farm labor, it is said that one man with a tractor can accomplish more than two men with horses. This makes the labor problem involved in securing an increased yield relatively less serious with tractors than with animal power.

The Bureau of Standards is undertaking to compile the present state of knowledge and practice concerning the numerical values used by engineers and others for the properties of metals and alloys, with a view to making generally available the most acceptable values of these constants and also as a basis for further experimental investigation. A form sheet is furnished containing the various items required. These cover the mechanical, thermal, electrical, and optical properties of value to the investigator and engineer. A sheet of instructions for compiling the table—with an illustrative filled-out form for commercial electrolytic copper—is included. This contains a list of the alloys on which data are particularly desired.

BY-PRODUCT COKE AND COKING OPERATIONS

By C. J. Ramsburg[1] and F. W. Sperr, Jr.[2], Pittsburgh, Pa.

On January 1, 1915, there were in operation 6138 by-product recovery ovens of various sizes in the United States and Canada, having a capacity to carbonize 24,000,000 tons of coal per annum, and to produce therefrom approximately 18,800,000 tons of coke. Despite the fact that in the interim practically five hundred ovens have been discarded, on January 1, 1918, there will be in operation, if present contracts are completed, 9900 ovens, having a capacity to carbonize 47,400,000 tons per annum, giving a coke production of 35,000,000 tons. In this three-year period by-product coke production will have practically doubled, and there will have been as much gain in capacity as in the previous twenty years.

The cause of this rapid increase has not been a desire to take advantage of the inflated prices for by-products due to war conditions, but a financial condition favoring large investments brought about by the war, and making it possible to carry forward plans made previously.

The most impressive fact is the conservation of our local supply brought about by the introduction of modern methods. It may be of interest to make a few calculations simply from the standpoint of *fuel values;* and to put the matter on the most conservative basis possible, let us figure such values in terms of coal.

Table 1 shows a total fuel saving of 825 lb. of coal per ton of furnace coke. The fuel value of the gas is put as against raw *coal,* B.t.u. for B.t.u. There is a further saving in the blast furnace of 200 lb. of coke per ton of beehive coke formerly used. Figured back on a coal basis, these 200 lb. of coke represent 282½ lb. of coal at the beehive oven, so that the total saving amounts to approximately 1100 lb. of coal—0.55 ton—for each ton of by-product coke made in the modern plant. Since the ovens added from January 1, 1915, to 1918 will produce practically 16,200,000 tons of coke per annum, it follows that they will save annually the fuel equivalent of 9,000,000 tons of coal.

Looking backward over the years consumed in bringing the coke oven to its present stage of development in America, there are some events which stand out preëminently. The first of these dates back to 1906. In that year the United States Steel Corporation was brought face to face with the necessity of formulating a definite policy as to its coke supply, and appointed a committee to study beehive coking and by-product coking and to make a recommendation to the company. The advice of this committee was quickly acted upon by the corporation in the decision to build a by-product oven plant at Joliet, Ill., in connection with the blast furnace and steel plant of the Illinois Steel Company, and to build that type of oven which they had found to give the most efficient results in European countries.

The success of this Joliet plant was so immediate that the corporation without delay proceeded with the construction of additional plants of the same type, including the largest by-product coke plant in the world at Gary, Ind., consisting of 560 Koppers ovens, and a plant of approximately the same size as the Joliet plant (280 ovens) at Ensley, Ala., for the Tennessee Coal, Iron, and Railroad Company.

The second event was the selection of silica material for one of the oven batteries at Joliet. The value of the silica in this connection is due to four characteristics.

TABLE 1 BY-PRODUCT YIELDS FROM COAL SUCH AS NOW USED TO MAKE FIRST-CLASS BY-PRODUCT COKE IN THE MIDDLE STATES DISTRICT

85 Per Cent High Volatile—15 Per Cent Low Vol.

		Fuel Value [illegible] Equivalent, [illegible]
To make 1 Ton Furnace Coke, 1.4 to 1.5 Tons Coal are Required. By beehive coking, the by-products wasted have a heat value equivalent to 625 lb. of coal.	*Surplus Gas, 5000 [illegible] B.t.u. Used as fuel.*	[illegible]
	Tar, 12 gallons. Used to make creosote oil, pitch, lampblack, various oils and dye materials.	
	Ammonium Sulphate [illegible] in form of 25 per cent ammonia liquor *33 lb.*). Used for fertilizer, for refrigeration, and for nitric acid and other chemical manufactures.	No [illegible] credit
	Benzols as light oil [illegible] gallons. Used for motor fuel, dye-material base, phenol and other chemical manufacture, solvent and cleanser.	[illegible]
	Coke Breeze, 120 lb. Used as fuel.	[illegible]
	Total	625
Add coal equivalent wasted in beehive oven		200
Total economy of by-product oven per ton coke		825

1 The conductivity at high temperatures is superior to that of clay brick

2 The fusing or softening temperature is much higher than that of fireclay

3 The action under heat may be calculated with scientific exactness, due to its practically constant composition

4 The expansion and contraction of silica material between 2000 and 2600 deg. fahr. is practically negligible, so that when the material has once been heated to within this temperature range (under which condition the coking operations are conducted) no further appreciable movement takes place.

The third event was the realization that with uniform heat distribution in the ovens and with the use of silica material much higher heats and consequent higher coking velocities could be employed, and, further, that, with the lower coking periods, higher volatile coals could be used, with increased yields of by-products and equally satisfactory coke.

The result can be demonstrated by the fact that the Joliet plant of the United States Steel Corporation, put into operation in 1908, was originally planned to use from 70 to 80 per cent of low-volatile coal, and the coking time was figured at 24 hours. A coke plant of 640 ovens, now building at Clairton, Pa., near Pittsburgh, is so designed that it may be operated on 15 hours' coking time and is expected to use 100 per cent high-volatile coal. Even if this does not make quite as

[1] Second Vice-President, The H. Koppers Company.

[2] Chief Chemist, The H. Koppers Company.

Abstract of paper presented at a joint meeting of The Franklin Institute and the Philadelphia Section of The American Society of Mechanical Engineers, February 1, 1917.

[illegible] grade furnace coke [illegible] will work [illegible] broad lines to better [illegible], and time will tell where [illegible] comparison [illegible] opportunity [illegible] given the [illegible] operators to [illegible] the new type of coke.

The effect on the [illegible] by reference to Table 2.

TABLE 2 [illegible] OF COKE

	[illegible]	[illegible] *B*
	[illegible]	100 per cent
	[illegible]	high volatile
[illegible]	[illegible]	1.5 gal
[illegible]	[illegible]	38.0 lb.
[illegible]	[illegible]	10,000 cu. ft.
[illegible]	[illegible]	560
[illegible]	[illegible]	5,600,000
[illegible]	[illegible]	5.4 gal

A comparison in value of by-products on a basis of normal values shows a credit per ton of furnace coke of approximately \$1.25 in favor of the high-volatile coal.

The fourth event was the awakening to the fact that, while an increase in the cubical content of an oven tends to a reduction in plant cost and in operating labor due to handling larger units, a decrease in oven width would more than offset this unit-size advantage because of absolutely different conditions.

The reason for this becomes apparent with an understanding of the factors involved. Increased length of oven gives increased cubical content, and the ultimate economic length depends upon the mechanical and structural limits. Of increased height the same may be said, except that this involves questions of time of contact of volatile products and speed of their flow which modify the advantage and which are yet to be finally worked out.

Increased *oven width* involves an entirely different consideration. Practically all the heat supplied for the coking of the coal mass flows from the two walls toward the center. This flow of heat depends to a large extent on the resistance and temperature, and in the coke oven the average rate of coking depends, of course, on the rate of heat penetration. For example, it becomes apparent at once, in a comparison between a 16-in. oven and a 20-in. oven, that the following is true:

a With the same temperature of wall the average velocity of coking in the 20-in. oven will be less than in the 16-in. oven, and the time required to coke the 20-in. oven will be more than proportionally greater than the 16-in. oven

b To coke the 20-in. oven in the same time as the 16-in. oven, the wall temperature must be increased very markedly

c To coke the coal in the two ovens at the same average rate, the wall of the wider oven must be considerably hotter than that of the narrower one

d With the *same wall temperatures*, more coke can be made per day in the narrower oven than in the wide one

e To make the same amount of coke per day, the wall temperature in the 16-in. oven would be lower.

Four points are of great value in this connection:

1 Overcoked material is of less value in a furnace than a greener coke

2 The wider the oven the more overcoked the outside layers will be and the larger the proportion of overcoked material for a given output

3 The production of by-products is enhanced by reducing the wall temperatures

4 The life of oven brickwork is increased by being operated at lower temperatures.

The result of this reasoning was the decision, in 1914, to reduce the width of oven from $19\frac{3}{4}$ in., average then being built, to $18\frac{1}{4}$ in.

Plants of the reduced width are now in operation as follows:

	Ovens
Toledo Furnace Company	94
Youngstown Sheet and Tube Company	204
United Furnace Company	47
River Furnace Company	204

There is no doubt among those who have been acquainted with the wider ovens that the narrower oven has the following distinct advantages:

1 Less sponge in the coke

2 Better coke from the same coal

3 As good coke from higher volatile mixtures

4 Higher yields of tar, ammonia, and benzols

5 Low temperatures for the same coking velocity.

The fifth event in coke-oven development is the universal recovery of benzols. The war furnished the primary inducement to developing this phase of the industry; but the fact that the material might be disposed of advantageously for motor fuel after the demand for explosives would cease had an important bearing in stabilizing the large investments demanded.

Previous to the war comparatively few plants were equipped for benzol recovery; in fact, outside the plants of the Semet Solvay Company, operated for their own account, there was comparatively little benzol extracted, and this was used, for the most part, in enriching illuminating gas. Today practically every coke-oven plant in America has installed this recovery, and the production in 1917 will be in excess of 40,000,000 gal., rated as light oil, if continued at the present rate.

While the removal of benzol reduces the heat units in the gas, the loss in this manner is a very small factor, and the return to be secured from the sale of this product is likely to be greater than that secured from the recovery of tar.

One feature of the benzol credit as related to motor fuel is the smallness of the quantity compared with gasoline production, and, since benzol and gasoline are miscible, the utility of benzol will be enhanced by increasing the quantities available.

Experiments recently conducted by a large oil company on its trucks and passenger automobiles proved that not only is benzol more valuable than gasoline as a motor fuel when used straight, but its effective value is increased by being mixed with gasoline. While these experiments are not complete, nevertheless they indicate that a mixture of equal parts of gasoline and benzol gives a value over 16 per cent greater that that of straight gasoline, which shows 32 per cent increased value for the benzol half. In 1917 there will be produced in this country over 1,000,000,000 gal. of gasoline, so, while the value of benzol is stabilized, for this reason it cannot be a very great factor in the motor-fuel situation. Every means should be taken not only to secure additional quantities from a standpoint of *preparedness,* but from a standpoint of motor-fuel supply.

In connection with the value of benzol as a motor fuel there is an interesting fact which may in the future have a very marked influence. In many quarters alcohol is looked upon as the ultimate fuel, but it cannot be employed except with less efficiency and with greater difficulties, due to its high

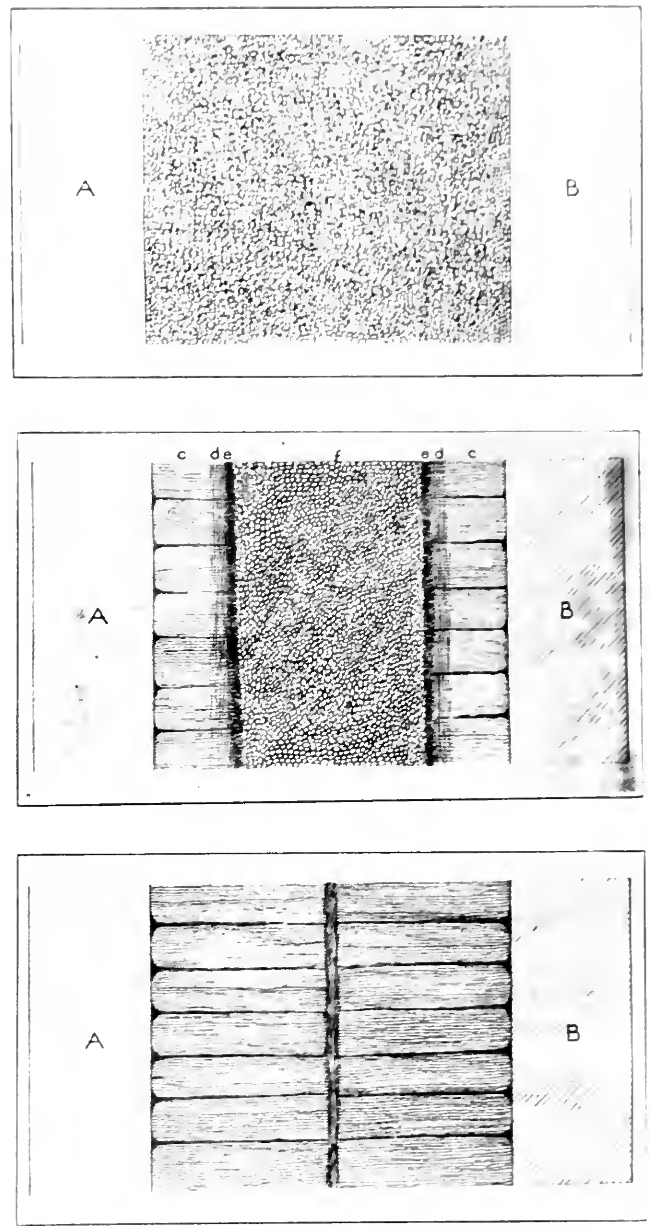
hydrogen content. Commercial alcohol and gasoline are not miscible. Alcohol and benzol are miscible and make a most efficient fuel, and, further, *after the addition of benzol to alcohol* the mixture will carry quite a high proportion of gasoline. The future may see benzol as the tie between gasoline and alcohol, permitting a piecing-out of the gasoline supply and an introduction of alcohol as a commercial motor fuel.

Taking up in somewhat more detail the study of by-product coke and its use in blast furnaces, the phenomenal growth of the by-product industry has stimulated a renewed interest in the main product. This interest is due, first, to the recent revolutionizing of ideas regarding the relative values of by-product and beehive coke. The tardy recognition of the fact that by-product coke of a fairly wide range of origin, when properly used in the blast furnace, gives results not merely as good as, but much *superior* to, those obtained from beehive coke, was accompanied by a realization that the limit of efficiency had by no means been reached; that Grüner's "ideal performance"— long the *ne plus ultra* of blast-furnace men —was actually being surpassed by many blast furnaces, and that much regarding the question of coke economy still remained to be learned. In the renewed study of the subject that this realization is just beginning to stimulate, we have the inestimable advantage that the by-product coke plants are being located in proximity to, and usually under the same management as, the blast furnaces that they are intended to supply, instead of at the coal mines as was the case with the beehive ovens. Thus the blast-furnace operator knows better the sources of the material that he has to use and the conditions under which it was produced, while the coke-plant operator can more intelligently regulate the performance of his ovens and the quality of his product, according to the requirements of the furnace. Above all, the combination and coöperation of the two plants result in a regularity of performance that is perhaps more to be desired than any specific quality of material. It is to be hoped that this coöperation may soon be extended to the foundry and other industries using coke as fuel.

It will assist in following the few descriptive studies of coke that we have to present, to give a brief account of the generally accepted theory of the coking process. The development of this theory is due to several German investigators, notably Much,[1] Hilgenstock,[2] Rau,[3] and Simmersbach,[4] and it has received such abundant confirmation from every practical standpoint that there can be no question of its soundness.

Let Fig 1 represent a section across a by-product coke oven immediately after the charge of coal is introduced. The layer of coal next to each wall *A* and *B* is very rapidly heated. A complicated process of destructive distillation begins, and at a temperature of about 375 to 400 deg. cent. the layer becomes soft and pasty. The pasty mass is for a time in a state of violent ebullition, due to the rapid expulsion of its volatile matter, and then rapidly solidifies, the [illegible] residue retaining the vesicular form and structure of the pasty, foaming stage.

The adjacent layer toward the interior has in the meantime reached the pasty stage, the fusion being assisted by the penetration of some of the soft material forced over from the outer layer. The gases and vapors follow always the line of least resistance and pass through the porous outer layer and up along the wall of the oven, as indicated by arrows, and not through the viscous inner portion of the fused zone and then through the mass of coal. In passing through the highly heated porous layer, the hydrocarbons undergo a partial secondary decomposition, depositing part of their carbon on the cellular surfaces just formed, thus building up and strengthening the coke. The coking process is thus to be conceived as [illegible]



Figs. 1 to 3—Diagrams of the Coking Process

the formation of a fused zone, and the gradual advance of this zone toward the center of the oven, the evolved gases and vapors depositing part of their carbon in the vesicular mass left as the zone progresses. The condition of the material in the oven when the coking has fairly well advanced may be represented by Fig. 2: *c* is the portion already coked, *d* is the fused zone merging into an adjacent zone *e*, which, being in a state of incipient fusion, is more viscous; *f* is the uncoked coal.

The actual thickness of the fused zone is probably not over ½ in. The drop of temperature across this narrow zone is very great, and the interior of the oven remains compara-

[3] Stahl und Eisen, 1910, p. 1240.

[4] Grundlagen der Kokschemie, Berlin, Julius Springer, 1914.

tively cool, [illegible] at about [illegible] the coking process. Simmersbach's experiment[1] [illegible] Koppers oven of 500 mm. (19.7 in.) mean width [illegible] 29 hours' coking time with a final maximum temperature of 1100 deg. cent., showed that the temperature in the middle of the oven, 1 meter above the floor, remained about 100 deg. cent. for 2.5 hours after charging, then rose to 100 [illegible] and remained at this temperature until [illegible] hours after charging. At 20 hours the temperature was only 410 deg. cent.

The rate of advance of the two zones toward the center of the oven depends principally upon the temperature of the walls A and B. In present practice, with ovens 18 in. wide and wall temperatures about 1000 deg. cent., the average rate is about [illegible] in. per hour. The initial rate is, however, much more rapid than this, and decreases as the center of the oven is approached.

Fig. 4 Coke in By-Product Oven Just After Removing Door

As the coking progresses, cracks or joints develop perpendicular to the walls of the oven, thus determining the blocks of coke as they are eventually formed when the oven is discharged. These cracks form avenues of escape for a large percentage of the gases, hence the amount of deposited carbon is greater in proportion on the surfaces of the blocks than in the interior. Eventually the two zones merge at the center of the oven (Fig. 3), and, with the practically complete expulsion of the last of the volatile matter, the coking process is finished. There is always a distinct parting in the center of the oven, so that the length of the blocks is equivalent to about half the width of the oven. Fig. 4 shows a view of the coke as it appears when the door of the oven is removed. Most of the coke immediately adjacent to the walls of the oven is covered with a skin of carbonized pitch. The true form of the blocks may be seen in a few places where this has been broken away.

Fig. 5 Blast-Furnace Coke, Atlantic District

Fig. 5 shows a view of a typical coke. In this figure the individual blocks may be seen distinctly. A few characteristic blocks are shown in Fig. 6. The three smaller pieces in this figure are cross-sections. The end of the block (Fig. 7) originally adjacent to the wall of the oven may always be distinguished by its cauliflower-like appearance and dense layers of deposited carbon. We shall designate it as the wall end and shall call the other extremity the center end, for want of a better term. The structure of the coke toward the center end is always more open, and occasionally is somewhat spongy.

The shape of the coke is quite characteristic, depending upon the coal from which it is produced, and also, to a considerable extent, upon the method of heat treatment. The coke-oven man classes his product as either *blocky* or *fingery*, coke of the former character being preferred. Some typically fingery coke is shown in Fig. 8. As a rule, the coke from coals of over 30 per cent volatile matter is apt to have a fingery tendency—and this becomes highly pronounced if the coal has a high oxygen content. By coking such coals very slowly at temperatures somewhat lower than used in ordinary practice, the fingery tendency may be disguised or in many cases entirely eliminated. By disguising it, we mean that the product will actually appear to form large, massive blocks,

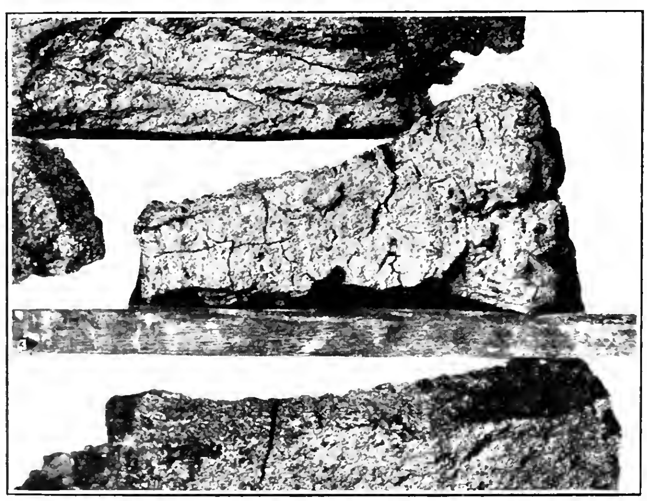

Fig. 6 Typical By-Product Coke

[1] Stahl und Eisen, June 11, 1914, p. 974.

but these blocks, if closely examined, will be found actually to be bundles of slender pieces more or less firmly cemented together. However, if the heat treatment be very carefully regulated during the coking process—especially in ovens designed and adapted to this particular type of coals—genuine, firm, blocky coke may be made from many coals usually regarded as producing only the fingery variety.

The size of the blocks is affected to a certain extent by almost all the conditions pertaining to the manufacture of coke. The length is, of course, dependent upon the width of the oven, the average being, on account of shrinkage, a little less than half the width of the oven. The blocks from the top of the oven are usually (especially with high-volatile coals) shorter than those from the bottom. Overcoking and high temperatures tend to produce small-sized coke.

Coming now to an examination of the natural surfaces of the blocks, we may, in the first place, disregard the color as being relatively unimportant. It depends largely upon the method of quenching, and, to some extent, on the quality of the water used, the use of large amounts of water causing a dark color, while with the careful use of a minimum quantity of water a light gray color can always be preserved. The majority of cokes produced from the standard coking coals rich in hydrocarbons and low in oxygen have close-textured, even surfaces, with possibly a few narrow, transverse zones of slightly larger cell openings interspersed between the two extremities. Many cokes from coals of the Connellsville (Pa.) type show the same silvery, glossy skin that used to be so much prized in beehive coke. This is probably indicative of a very heavy deposit of carbon, especially favored by slow and uniform evolution of a very rich gas.

Other cokes fully equal in value to the above are characterized by a peculiar shaggy appearance, as if they were covered with blotches of dark moss. This appearance is usually found in cokes produced from mixtures of eastern coking coals with the somewhat more highly oxygenated coals of the central field. Oddly enough, both types of coal usually make smooth coke if carbonized separately.

Certain cokes present transverse pebbly seams—usually not more than two or three. These seams are very narrow and quite coherent, and may be shown to be composed of small globules of quite pure carbon, with no apparent cellular structure. This phenomenon again appears to be characteristic of the more highly oxygenated coals.

The surfaces always show more or less transverse and longitudinal cracks, significantly at right angles—either parallel or perpendicular to the wall of the oven. Naturally these are an element of weakness, and their presence to any excessive degree is one of the surest "first-hand" indications of an inferior grade of coke that we have. The amount [illegible] can be controlled to a surprising extent [illegible] heat treatment.

By breaking a piece of coke [illegible] faces we find revealed the cellular structure [illegible] istic of all cokes and which can [illegible] opment simply by inspecting the [illegible] surfaces. No definition of coke is complete that does not take this cellular structure into account.

The usual way—and the easiest—to examine the cell structure is to break a piece of coke crosswise and note the appearance of the fresh surfaces. Great care must, however, be taken, in comparing one coke with another by this method, to break the pieces at approximately the same distance from the wall end, since the cells are apt to increase considerably in size from the wall to the center. Oddly enough, in many cokes there is a characteristic difference in the two surfaces of a break. No matter where the piece is fractured, the surface on the wall side has always a granular appearance, with a steel-gray luster and well-defined cell openings. The opposite surface (i.e., looking toward the center of the oven) has a characteristic graphitic luster, with the cell openings flatter and possibly not so sharply defined.

Although this difference is rather hard to depict photo-

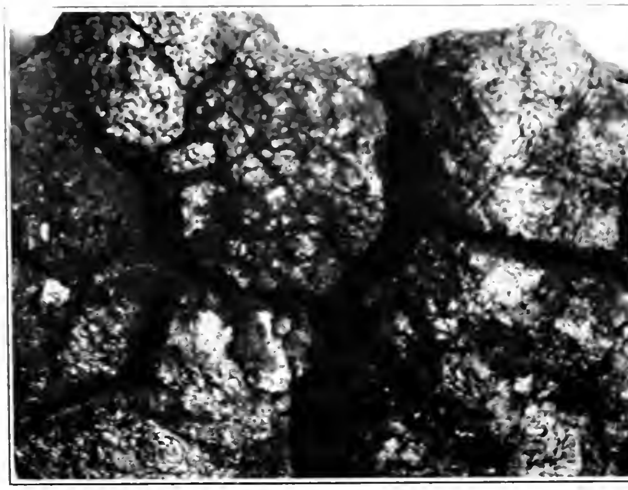

Fig. 7 Wall End of a Block of Coke

Fig. 8 Fingery Coke and Sponge (Colorado Coal)

graphically in a satisfactory manner, we have attempted to show in Figs. 9 and 10, which will also show the variation in the sizes of cells from wall and to center. The sections have been made with a 1/16-in. emery wheel at 2, 4, and 6 in. from the wall end of the block of coke. This is a standard blast-furnace coke made from a mixture of West Virginia and Pennsylvania coals, and is the same as shown in Fig. 15.

For any accurate comparison of the cell structure of different cokes we prefer to make longitudinal sections with a thin emery wheel—such sections as are shown in Figs. 12 to 17. If this is done, the danger of confusing sections made at different distances from the wall will be largely eliminated. It must be mentioned that *breaking* a piece of coke longitudinally so as to reveal the real cell structure is a decidedly difficult matter. Almost always the break will be found to be made along the plane of a natural longitudinal fracture.

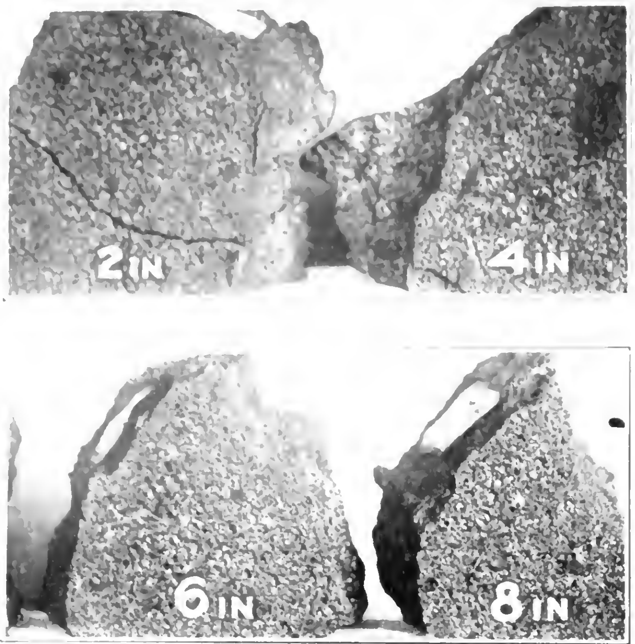

FIG. 9 CROSS-SECTIONS OF COKE SHOWING SURFACES TOWARD CENTER
(At marked distances from wall)

and the exposed surfaces will be found to be covered with deposited carbon.

Great importance has been attributed to the cell structure of coke by all authorities on the subject, and especially by blast-furnace operators, and yet the subject is very poorly defined and no standards of comparison have been established. We have recently begun the use of a simple system, analogous to the scale of hardness used in the study of metals, which we hope may come into general favor. At present we employ a set of four standards, shown in Fig. 11. These are all longitudinal sections, cut from blocks of typically different cokes.

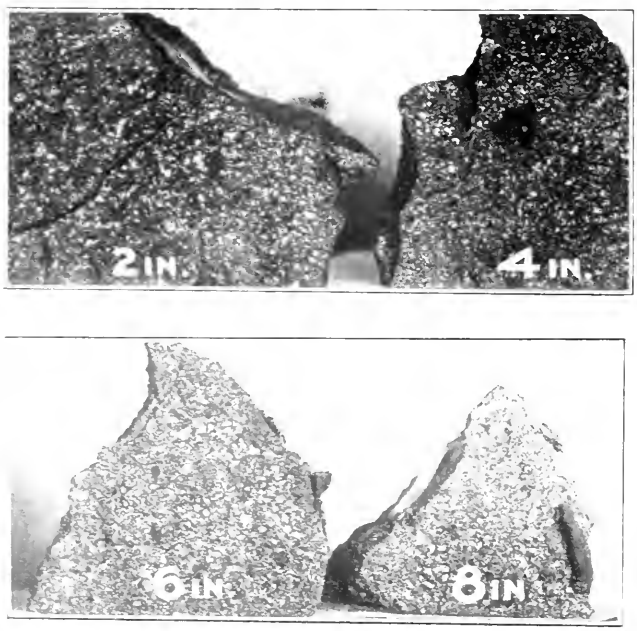

FIG. 10 CROSS-SECTIONS OF COKE SHOWING SURFACES FACING TOWARD WALL
(At marked distances from wall)

The sections are the same length, and each is cut beginning 1 in. from the wall end. The sections are numbered 1 to 4 in order of increasing cell size. With such a set of standards it is easy to grade any coke according to its cell structure, and the grading will convey a much more definite idea than the loose terms of "dense," "close," "rather close," "fairly open," "medium," etc., hitherto used.

In addition to grading cokes according to size of cells, we may also classify them as regular or irregular in cell structure. The standards would all be considered as regular in structure. This does not mean at all that the cells are of the same size,

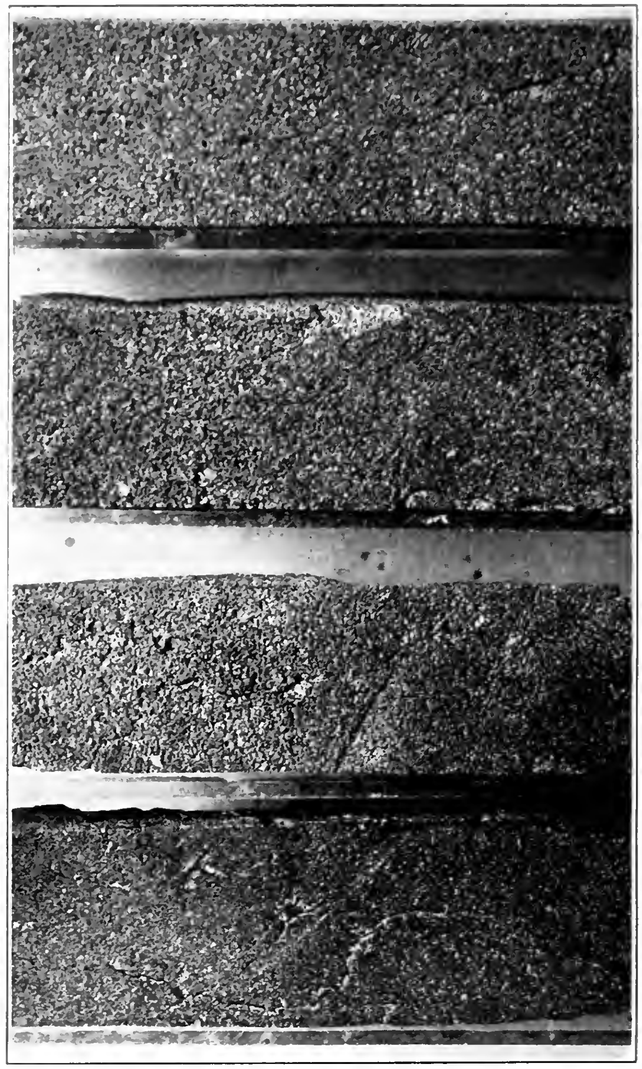

FIG. 11 STANDARDS FOR GAGING CELL STRUCTURE
(No. 1 at bottom; No. 4 at top)

but their general arrangement gives an easily perceived impression of regularity. What we mean by irregular structure is illustrated by the sections shown in Fig. 12. This sort of coke has alternate patches of close and open texture, and is frequently produced by the more highly oxygenated class of coking coals, as well as by mixtures of coals having decidedly different characteristics.

It might possibly be thought now that an interesting table could be prepared grading the cell structure of cokes produced from various typical coals. Such a table would be well-nigh valueless unless the data were carefully qualified by details regarding preliminary treatment of each coal, dimensions of ovens, temperatures, coking time, and several other

factors, each of which plays a part in the development of cell structure. It may be more profitable to show a few sections

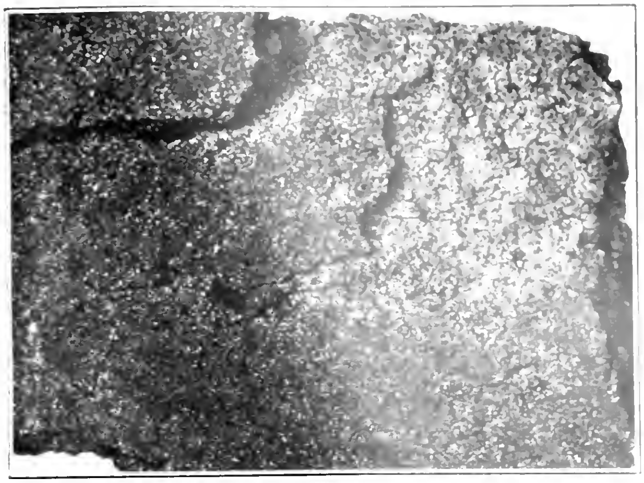

Fig. 12 Coke from Elkhorn Coal [illegible] Per Cent Pocahontas

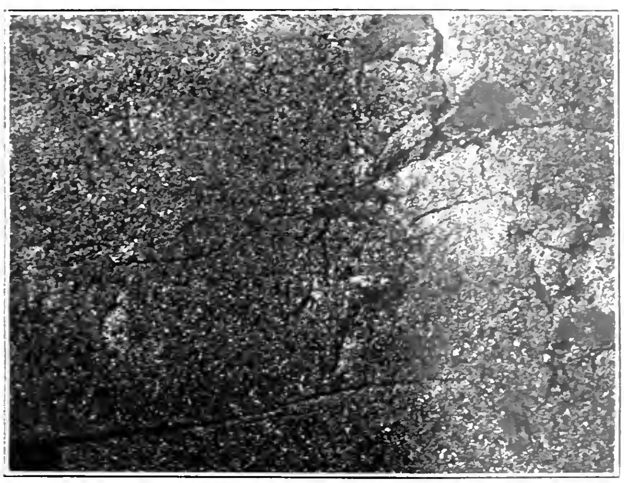

Fig. 13 Coke from Mixture of Pennsylvania and West Virginia Coals

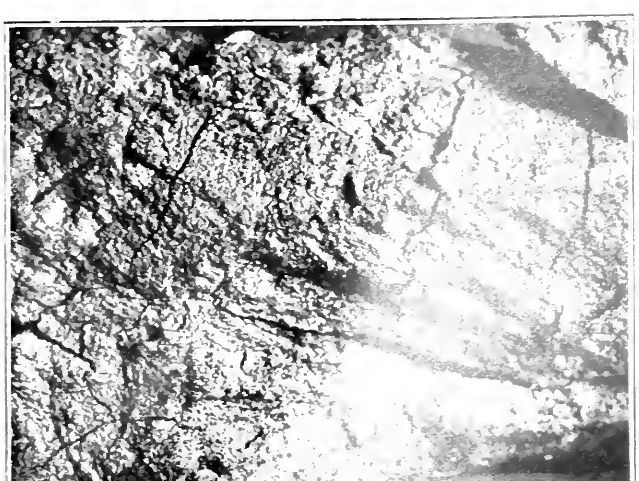

Fig. 14 Coke [illegible] Coals

of different cokes that have [illegible] successful results in blast-furnace and foundry practice in various parts of the country

Figs. 12 to 17, inclusive, illustrate some specimens carefully selected to be as representative as possible.

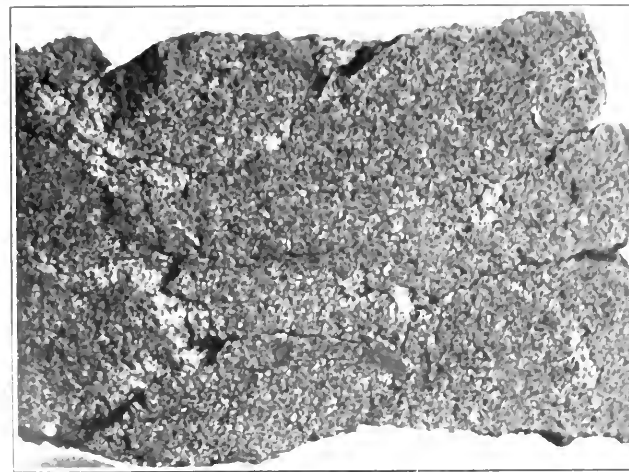

Fig. [illegible] Coke from Kentucky Coal, with 15 Per Cent Pocahontas

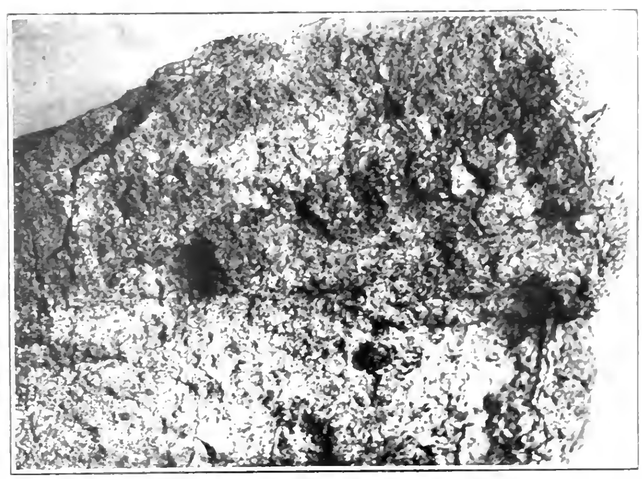

Fig. [illegible] Coke from Pittsburgh Coal, with 20 Per Cent Pocahontas

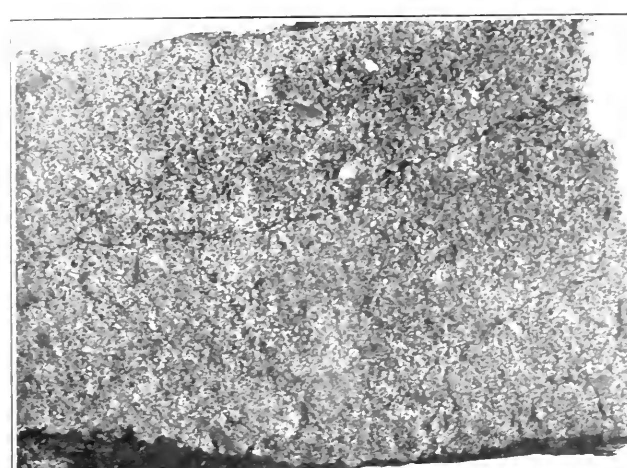

Fig. 17 Coke from Pittsburgh Coal, with 40 Per Cent Pocahontas

Sometimes too much reliance is placed in the determination of the specific gravity and porosity of coke. Figures as to

Fig. 18 Standard No. 1 Enlarged 10 Diameters

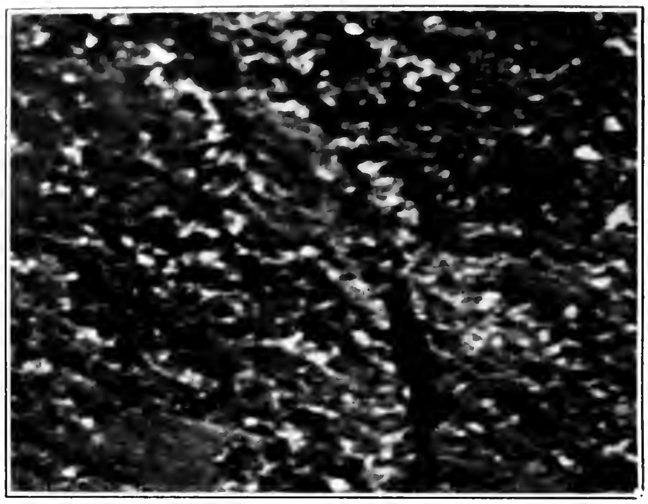

Fig. 19 Standard No. 2 Enlarged 10 Diameters

porosity or the percentage of cell space in the total volume of coke are almost valueless unless supplemented by an examination of the actual size of cells and thickness of cell walls. A coke of close texture and thin walls may have the same percentage of cell space as one having large cells and relatively thick walls. As John Fulton[1] the pioneer investigator of coke, said, 34 years ago: "Mere cellular space . . . cannot be used as an element in the practical determination of the value of cokes for blast-furnace use. Furnace gases cannot act on cell spaces; they can only act on exposed surfaces." It is the cell walls and surfaces that are the most important. Cell space and porosity, which is the measure of it, are merely incidental.

Table 3, which gives the specific gravities and porosities of coke specimens, will show that there is really no relation between cell structure and porosity.

For ordinary purposes in grading cell structure magnification is unnecessary. Photographic enlargement gives some interesting information as to the character of the cell walls. Figs. 18, 19, 20 and 21 show portions of standards Nos. 1, 2, 3, and 4, respectively, each enlarged 10 times. There is considerable apparent irregularity of cell diameter, due to the fact that the cells are cut in different planes, but the comparison of the four types of coke is fairly good.

[1] Bull. Am. Inst. Min. Eng., October, 1883.

In passing from this subject of the examination of coke sections we would take occasion to point out the interesting field

TABLE 3 SPECIFIC GRAVITIES AND POROSITIES OF COKE SPECIMENS

Cell grading	Figure	Apparent specific gravity	True specific gravity	Porosity
1 (Standard)	11	1 097	1.917	42.8

4	15	0.917	1.921	52 3

open here for the application of petrographic methods to an exhaustive investigation of the material. The actual chemical and physical state of the carbon produced from various coals under various conditions is an important matter from a practical standpoint. Differences in the true specific gravity of coke are frequently found that cannot be explained by varia-

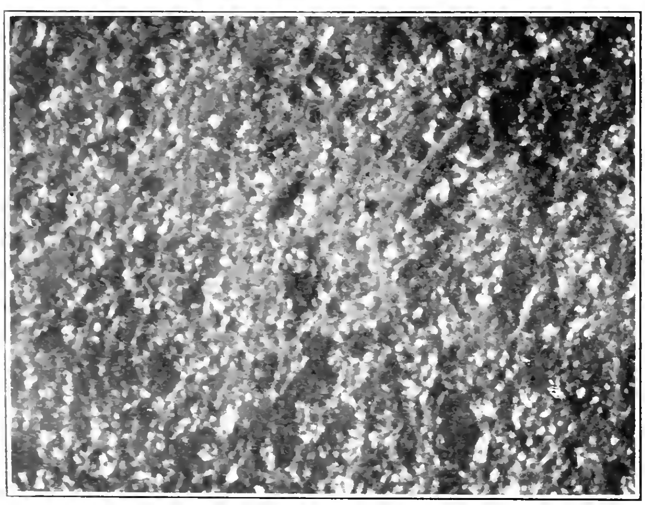

Fig. 20 Standard No. 3 Enlarged 10 Diameters

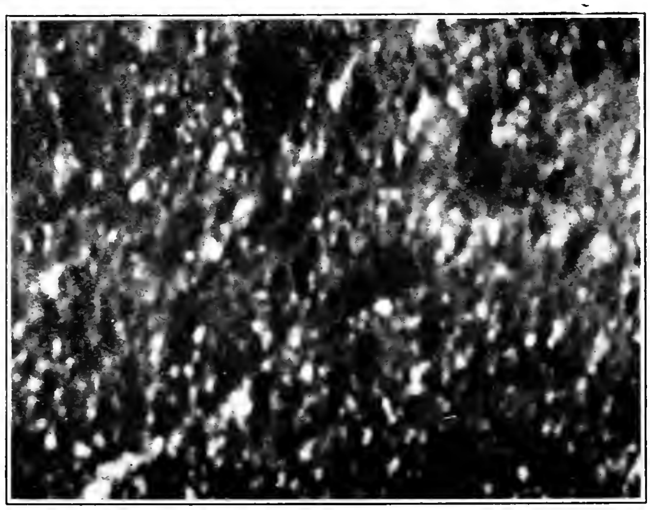

Fig. 21 Standard No. 4 Enlarged 10 Diameters

tion in the content of inorganic matter. The actual condition of this inorganic matter after carbonization, the amount of reduction of the various oxides, the possible effect of the finely disseminated mineral matter in strengthening or weakening the cell walls are all very important. Inorganic matter does not necessarily constitute an element of weakness. Large particles, especially if segregated, are injurious, but finely divided mineral matter may actually strengthen the cell walls. High-ash cokes are frequently stronger than low-ash cokes from the same kind of coal. Some experiments in washing and coking coals of moderate ash content have shown that where the original coal gave a strong coke, the washed coal gave a weaker coke, the difference being undoubtedly due, to some extent, to the removal of some of the mineral matter, although the high moisture content of the washed coal might have had some effect. Simmersbach gives some evidence to show that iron present in combination with carbon and silicon, and silicon present as a silicon carbide, may be the cause of the remarkable hardness of some coke.

Studies of this character will, however, be largely of academic interest unless correlated with studies of the behavior of different types of coke in the blast furnace and in other types of apparatus in which the material is used. Let us choose the blast furnace for consideration here on account of its tremendous industrial importance.

There is at present some disagreement among blast-furnace men as to the exact function of the coke in the most efficient and economical reduction of iron ore. The majority probably still accept Grüner's theory of ideal working, viz. (as stated by Richards[1]), "All the carbon burnt in the furnace should first be oxidized at the tuyères to CO, and all reduction of oxides above the tuyères should be caused by CO, which thus becomes CO_2." It is well known that the reduction of iron oxide by carbon monoxide is the most efficient from the standpoint of heat economy. Richards, however, has pointed out that the direct reduction of iron oxide by carbon is three times as efficient from the standpoint of carbon required as the indirect reduction, and says:

"The ordinary furnace produces at the tuyères, in order to get heat enough to melt down the charges, more CO gas than is needed to abstract all the oxygen from the charges; under these conditions it is uneconomical to oxidize any carbon at all above the tuyères. The exceptional furnace, because of pure ores, small amount of slag, pure fuel, high temperature of blast, or dry blast, gives heat enough at the tuyères to melt down the charges without producing enough CO gas to reduce all the charges; under these conditions, more or less reduction is effected by solid carbon and with the greatest economy in quantity of carbon required in the furnace."

About a year ago H. P. Howland prepared an interesting paper,[2] entitled Calculations With Reference to the Use of Carbon in Modern American Blast Furnaces, calling attention to the fact that many furnaces are actually operating with higher economy of coke than would be calculated from Grüner's theory; in fact, his calculations on the performance of 26 furnaces seem to show that what Richards regarded as the exceptional furnace is the rule rather than the exception in modern practice.

Howland's tabulation of data on these 26 furnaces is so interesting and pertinent to the subject that a portion of it is reproduced in Table 4.

Note incidentally the performance of the once-despised by-product coke in modern practice. Of the 19 furnaces using less than a ton of coke per ton of pig iron, 13 are burning by-product coke and 6 beehive coke.

Howland calculates that all the furnaces burning less than 1350 lb. of carbon at the tuyères are not making enough CO to reduce all the Fe_2O_3 and hence some of the latter must be reduced directly by carbon. He concludes: "It seems clear therefore, that in low-coke furnaces one of the most important (if not the most important) functions of the carbon burned at the tuyères is to produce heat to enable the carrying on of the direct reduction, rather than to produce CO for indirect reduction.

"On this basis, it becomes very essential that our carbon shall burn instantaneously to CO in order that the resulting heat may be localized where needed. This should not be a question of seconds, but of a fraction of a second. If our carbon is of such a nature that this burning to CO is a comparatively long process, more of it will be required than of the quick-burning carbon in order to obtain the same concentration of heat at the desired point.

"We would, therefore, say that the most desirable thing about a coke is that quality in the carbon which will allow of its being instantaneously burned to CO and thus result in the maximum concentration of heat where needed."

W. H. Blauvelt, in a discussion of Howland's paper,[3] says: "In studying the combustion of coke in the furnace, it is clear that the production of the maximum quantity of heat is not of the first importance in blast-furnace operation, or in the utilization of the fuel charged into the furnace. To my mind, the production of a high thermal head at the tuyères is of the first importance, and the best coke is that which reaches the tuyères in proper condition to produce the highest temperature at the tuyères, and in just sufficient quantity to do the amount of work required there under the conditions produced by this

TABLE 4—PART OF HOWLAND'S DATA ON AMERICAN BLAST FURNACES

FIG. 23 COKE FROM SAME COAL AS FIG. 22, WITH 20 PER CENT POCAHONTAS

maximum temperature. The combustion of a much larger amount of fuel at the tuyères, under conditions that will fall short of producing the highest possible temperature, cannot produce as good results, either in fuel economy or output. . . . Nothing is more fatal to obtaining the highest temperature than an excess of combustion. In the blast furnace an excess of air dilutes and cools the products of combustion, reducing the maximum thermal head at the tuyères, and the larger volume carries the high temperature zone too high in the furnace. . . . It will probably be generally admitted that furnace coke should be of nearly uniform size, and many furnace managers are eliminating all coke below $^3/_4$ in. and above 4 or 4½ in.; also, that the best coke is that which is sufficiently strong to resist undue abrasion and crumbling by attrition with the stock, and of an open porous structure that will permit the most rapid combustion when it reaches the tuyères. Many large users agree that the coke should never be overcoked beyond the point of producing a sufficiently strong structure, as overcoking quickly reduces the combustibility.

"If Grüner's ideal gives the best furnace operation, we should want a coke that is resistant to the oxygen in the ore, but easily combustible at the tuyères, which is a contradiction of qualities. If my argument is correct, that the furnace man wants the greatest thermal head at the tuyères rather than the production of the greatest quantity of heat in the furnace as a whole, then he is willing to sacrifice some coke by solution in the oxidizing gases in the upper part of the furnace, provided he can obtain a sufficient quantity of coke at the tuyères, of a quality that will permit rapid combustion with the minimum amount of air, thereby giving him the maximum thermal head."

The desirability of the condition which Blauvelt aptly terms *a high thermal head* in the zone of the tuyères will be readily granted even by those who adhere to Grüner's theory. This condition should be attained even at a sacrifice of some carbon by solution loss ($CO_2 + C = 2CO$), and we are of the opinion that the importance of this solution loss is frequently overestimated. Most laboratory experiments made to determine the loss undergone by different cokes have been of little value, because they have been mostly made with pulverized samples, so that their original physical condition has been greatly altered.

We have lately tested the resistance of a number of cokes to the action of CO_2 at temperatures of 800 and 900 deg., and find the loss of coke pulverized to 40 mesh to be very much greater than the same coke prepared in small test pieces, ⅜ in. by ⅜ in. by 1½ in., so as to retain the original structure.

As furnace conditions are better understood, the possibility

FIG. 24 COKE FROM COLORADO COAL, SHOWING SPONGE

FIG. 25 COKE FROM SAME COAL AS FIG. 24, PROPERLY MADE

of the use of coke of a wider instead of a more restricted range of quality will become better recognized, with the express limitation that the supply for each furnace must always be absolutely uniform in quality. This requirement of uniformity cannot be too strongly emphasized, and it is almost equally necessary for the proper operation of the coke plant as the blast furnace; but this does not mean that there is one standard grade of coke to which all plants should conform so far as possible. As a matter of fact, the range of cokes that successfully qualify in practical operation is continually being extended, through necessity of one sort or another, with little general realization of the fact. In Figs. 12 to 17 we have already shown the cell structure of some cokes that are giving good results in different American blast furnaces, and the difference is fairly remarkable.

However, for each kind of coke there is evidently some limiting size for efficient service, i. e., just large enough to offer such a minimum surface of attack for CO_2 that the loss on this account is negligible, and small enough so that complete combustion may be effected in a minimum of time at the tuyères. Hardness of body is usually—though possibly not necessarily—proportional to the resistance of a given coke to oxidation by CO_2 or oxygen. The harder grades of coke should be used in smaller sizes—and this is a compensation automatically provided to some extent by the operation of the by-product oven. Similarly, cokes of close cell structure are more resistant to oxidation, but this may be offset to a large extent by softness. The coke of more open cell structure will probably require less rigid attention to sizing than the denser coke. The important thing is to determine the practical limits of these elements of size, hardness, and cell structure. It may be found that a coke of such structure as No. 1 of our scale may be unsuitable, no matter what may be its size or softness; but this ought to be proved by actual test and not taken for granted.

These considerations are of the utmost importance and encouragement to the coke-oven man, because, with a reasonable choice of coal, his control over the quality of his coke is almost unlimited, and, even with a very restricted source of supply, the possibilities of conforming to the desired standard by proper oven construction and regulation are still remarkably great. We propose to conclude this paper by showing two or three examples of what can be accomplished in the way of control of this sort.

One proposition that frequently presents itself is that of eliminating sponge. Sponge is a characteristic honeycombed mass formed in the center of rich volatile matter. It seems to be caused by an excess of pitchy material moving along with the fused zone in the coking process, and finally [illegible] in the center of the oven, where it is eventually [illegible] the production of this light porous material. Sometimes [illegible] sponge is found in loose, detached masses scattered [illegible] coke as it lies on the wharf after quenching, or [illegible] be found adhering very closely to the ends of [illegible] coke, and sometimes blending, without any clear [illegible] cation, into the body of the coke itself.

Although the amount of this sponge [illegible] very large, it is so bulky that its actual [illegible] is small. In one case where the amount of sponge seemed to be very large it was actually found [illegible] to 1.65 per cent of the total coke. Small amounts of sponge probably do no harm, most of the material being soon broken up in the operations of handling the coke, but the presence of the material undoubtedly occasions a certain loss of carbon, and so we usually try to get rid of it. The customary remedy—and one that always works—is to mix with the high-volatile coal sufficient low-volatile coal, which has the effect of absorbing the excess of bituminous material and eliminating the conditions of sponge formation. Pocahontas coal is the standard low-volatile coal that is employed by many of our plants. It is to be noted that different coals require considerably different percentages of Pocahontas coal to completely eliminate the sponge. Fig. 22 shows a coke from unmixed high-volatile coal (about 34 per cent volatile matter). A large amount of sponge is readily apparent. Fig. 23 shows the coal from a mixture containing 80 per cent of this same coal with 20 per cent of Pocahontas. The sponge is entirely eliminated and the structure of the coke improved.

Frequently it is too expensive a proposition to buy low-volatile coal for the sake of eliminating a little sponge, and

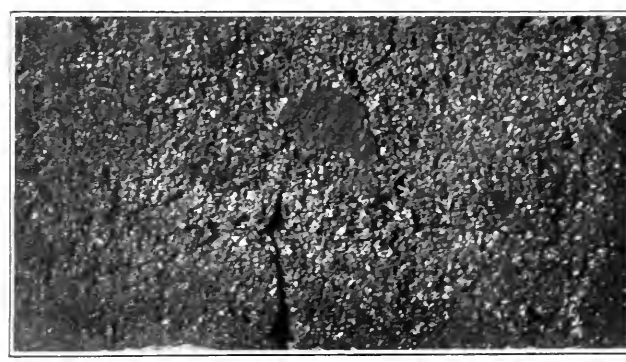

Fig. 26—Same Coal Mixture Coked at Different Plants Under Different Conditions

sometimes the low-volatile coal may be altogether inaccessible for practical purposes. This does not, however, leave us at the end of our resources. By proper methods of control, sponge may be eliminated from a wide variety of coals that produce it under ordinary conditions. If the oven is correctly designed and proportioned, and the temperature and coking are carefully regulated, very satisfactory results may be obtained without the necessity of making a special coal mixture. Fig. 24 shows the coke from one coal which was made in a type of oven unsuited to it, and coked at unfavorable temperatures. Fig. 25 shows coke made from the same coal under proper conditions. The sponge has been entirely eliminated.

Occasionally one of the most difficult problems to be overcome is that of too great density of cell structure. Here, again, we can approach the problem in two ways: one, by mixing in one or more other coals that have a tendency to the production of a more open cell structure, and the other way by suitable preliminary preparation of the coal, careful heat

[illegible] and special design of the ovens. Fig. 26 shows coke made from the same coal mixture coked at different plants under different conditions. The dense coke shown in the lower part of the figure was greatly improved upon when the nature of the coal was better understood, and the excellent product shown in the upper part of the figure was then made when the coal was treated in the right kind of ovens and under proper conditions.

To insure the best results a special study must be made of each kind of coal it is proposed to use, and it would be well, in all cases where a new plant is contemplated, to make this study previous to design of the plant, because the results may suggest some necessary changes in design that would not otherwise be foreseen.

Technical Education in Great Britain[1]

IN THE early days of our Institution most engineers were trained entirely in the shops. Theoretical knowledge was uncalled for, and even held to be antagonistic to practical success. There was no supply of scientific engineers. It was only in 1840 that the chair of engineering was established at Glasgow University. There were engineering courses in London at King's College, and courses dealing more particularly with mining and shipbuilding at the School of Mines and at the School of Naval Architecture. In the provinces there were a few technical colleges. It was not till 1877 that the livery companies of London appointed a committee to consider a national scheme of technical education. The City and Guilds Central College was the result. Then came the appointment of the Royal Commission, which reported in 1884, the formation of the National Association for the Promotion of Technical Education in 1887, and the Technical Education Act of 1889, which refused to the schools it governed the means of teaching the practice of any trade. In 1890 only was a real foundation laid by the transfer of the control of technical education from the school boards to the local authorities.

The result has been a vast expenditure on technical schools, ranging from the technical school of the small borough to institutions of university rank like the Municipal School of Technology in Manchester. Besides these we have provided engineering courses in most of our older universities, and endowed new ones. To Oxford, Cambridge, St. Andrews, Glasgow, Aberdeen, Edinburgh, Dublin, Durham, London, we have added Manchester, Wales, Birmingham, Liverpool, Leeds, Sheffield, Bristol, Belfast, and the National University of Ireland.

With all these schools and colleges, the problem of educating engineers and engineering workmen has not been solved. Our innate conservatism ties us too much to traditions. Many still fail to understand that the manual training which enabled an apprentice to become a master craftsman does not suffice to turn a schoolboy into an engineer. Moreover, differentiation is needed in training. Designers and scientific advisers require a knowledge and experience which managers and business organizers can forego, etc. This lack of differentiation seems to be one cause of the inefficiency of our technical education. Another certainly is insufficient preparation of those entering the technical schools.

The education available for the higher ranks seems fairly satisfactory; at all events, it has produced men capable of solving many problems presented by the war. I would give one caution and make one complaint. There are many Englishmen of the best type with initiative, ability to organize, etc., but incapable of assimilating much book learning, especially higher mathematics. Do not let us force these men through the same collegiate course as men of different mentality, but keep them to more elementary work and require a high standard in examination. We must not underrate these men. Many of them are of our very best. The Institution recognizes their value by admitting them without examination at 30 years of age.

My complaint is against retaining Greek as a compulsory subject at Oxford and Cambridge Universities.

The education provided for the workmen is most unsatisfactory. Trade apprentices who enter the shops at 14 years of age seldom have subsequent opportunities for learning other than at evening classes. I have seen in some paper that technical education in England and Wales is provided in 6,876 evening and similar schools, but that the average attendance is about one hour per week. The workman must have better education to qualify him to rise if capable, and to give those who have not the ability to rise some interests outside their daily work and football matches. Unless an antidote be provided, the monotony of repetition work will crush initiative and mental vigor, and instead of skillful workmen we shall breed incompetent machines.

The interests of engineers require two classes of institutions giving technical instruction, each with its definite purpose: (1) technical "colleges," (2) technical "schools" (senior and junior). The technical "colleges" should be of university rank, and should be departments or faculties of universities, like the Municipal School of Technology in Manchester, not independent of them, as in Germany. They should provide two courses, one for the scientific advisers and designers, the other for the managers and business organizers. They would receive their students mainly from the higher secondary schools. The gate should be opened only to those capable of profiting by the teaching. The idea of university education for the million is most pernicious nonsense. The technical "schools," both senior and junior, should also have two courses, one for men likely to become foremen or supervisors, the other for those likely to remain manual workers. These courses should not be purely technical. The schools would receive their students from the elementary and lower secondary schools. They should remain under the local authorities, so that the technical teaching might be varied in accordance with the local trades.

Another desideratum is coördination, especially between the higher secondary schools and the technical colleges, and between the elementary and lower secondary schools and the technical schools, so that pupils passing from the one to the other would be properly prepared for the change.

[1] From Presidential Address, Institution of Mechanical Engineers, April 20, 1917, by Michael Longridge.

The U. S. Bureau of Mines has received an offer of the complete laboratories and working staffs of the Minnesota School of Mines, Minnesota Mines Experiment Station, New York State School of Clay Work and Ceramics, Department of Chemistry, University of Texas, University of Cincinnati, Department of Chemistry, Louisville University, State Board of Health Laboratory, Ohio State University, and the Johns Hopkins University.

Commercial and other laboratories have also offered their services, among them being the Mellon Institute for Industrial Research; the General Electric Company; the Central Testing Laboratory, New York; the Fuel Engineering Society, New York.

PREPAREDNESS

By A. M. LOCKETT, NEW ORLEANS, LA.

Member of the Society

THE word *Preparedness* carries the idea of doing something in advance of an expected event in order that such event may be successful. Preparedness for the defense of the nation at a time of peace and with no immediate prospect of war is an abstract proposition which may be properly discussed as such. But when the nation is in a state of war, preparedness is no longer an abstract proposition but a condition which calls not for discussion but for *action*.

With this understanding of the proposition the subject becomes a question of not how we should prepare for a possible war but how we shall conduct a war which is now on our hands.

I have no technical knowledge to qualify me for advancing any views as to the manner in which military operations should be carried out. All that I can do is to give my personal views as to what I conceive to be the things which engineers can and should do to serve their country.

While it has always been the universal desire of the American people to avoid war, it certainly is also the intention of all Americans to win any war in which they are forced to engage.

It is useless now to waste time discussing the causes which led up to the war—the proposition before us is to discuss the ways and means of winning the war which is now beginning.

Many of us undertake work involving engineering design and construction varying in character and magnitude, but none of us has ever undertaken, or even conceived, of so large a contract as the American people are now called upon to execute.

This is not a job upon which we have the option of bidding or not bidding. The contract has been awarded to us and our certified check, which is nothing less than the sacred honor of our country, has been deposited and will be forfeited unless the job is successfully carried out.

The plans for this undertaking have been made by the Army and Navy. It is not for us, the American people, to find fault with these plans; our work is to carry them out with dispatch and completeness. The men who have made these plans have been trained from their boyhood in this line of work, and it would be foolish for us to assume that these plans are in any degree defective or incomplete. Therefore, the first duty in my opinion for all the people of this country is to get behind the Army and Navy and back them up to the absolute limit if we hope to execute the work successfully.

Every citizen of the United States is in theory, and in fact, in the service of the Government, whatever may be his occupation, or even if he has no occupation whatever. Every American citizen recognizes the obligation of coming to the defense of the nation in time of war, and if he is of sound mind he must know that such defense, to be effective, must be preceded by the necessary preparations.

In war patriotic fervor and enthusiasm play a prominent part, but the real work must be done by the men who have a clear understanding of the task, a full knowledge of the sacrifices to be made and a grim determination to carry out the program whatever the cost.

All men desire to win in any contest in which they engage. They may regard with equanimity the possibility of defeat when the penalty involves only loss of money or personal prestige, but when defeat involves loss of national integrity or national honor, no patriotic citizen can ever entertain the thought of defeat.

This being the case, any man who deliberately blocks or attempts to prevent the carrying out of any measure of preparedness which in any degree reduces the danger of defeat, is no more nor less than a traitor.

There may be differences of opinion as to whether a certain measure may in fact improve the chances of victory, but when all men agree that if certain things are done the probable outcome of this war is more to our advantage, to gamble upon the possibility of such measures not being needed is the height of folly.

It is fortunate for us in this emergency that we have had the opportunity to witness the practical demonstration which has been taking place in Europe for more than two years, because many theories previously advanced on the subject of military preparedness and national security have been proved untenable.

Germany has been able, by reason of the preliminary arrangements which we call Preparedness, to resist with marked success enemies many times more numerous, and it would be foolish for this country to fail to profit by her example in so far as practical preparations with respect to land operations are concerned. Likewise the British Navy has demonstrated that superiority of equipment is absolutely conclusive with respect to naval operations. We are confronted with a war which may involve both land and naval operations, and it is our duty to profit by what we have learned from these other great nations.

No comprehensive plan of preparedness can be carried out without the full coöperation of the whole people. The people will not back up any project which they do not believe sound in principle and necessary for the good of the country. There are some propositions involving merely economic policies upon which the people will take sides and follow leaders, more or less blindly, although they may not fully understand the principles involved; but when it comes to the question of war which calls for the sacrifice of all they hold dear, even to their lives, they must be roused not only to understand the necessity but they must have such a deep-seated conviction of the righteousness of the cause as they have in their religion.

It devolves upon us who are converted to convert those who have not yet seen the light, and one of the purposes of this paper is to attempt to point out the way the non-military engineers can assist in bringing the people to a proper understanding of the situation so that they will do what they should do.

In determining what is the duty of us engineers in this

Presented at a Joint Meeting of the New Orleans Section of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, and the Louisiana Association of Members of the American Society of Civil Engineers, on April 2, 1917.

mergency I make the suggestion that we can serve in two capacities: one as ordinary citizens, having an equal part with other citizens in influencing the actions of Congress, and the other in the capacity of engineers having technical knowledge and practical experience in work closely allied to the operations of the military engineers.

I believe that as citizens we should take the lead in the campaign of converting the people in general to a full realization of the situation, because we are qualified by our training to gather together in intelligible shape the facts and figures bearing upon the subject and to present them to the public in a manner which may be more easily understood by the average citizen than if those same facts and figures were included in a more or less technical explanation such as would ordinarily be made by military engineers.

As I have already said, the people will not get behind this movement with the proper spirit unless they are thoroughly convinced, first, that the preparedness movement is sound in principle, and second, that the actual necessity now exists.

I take it that no man who has made any attempt to post himself regarding the actual condition of this country with respect to preparedness, denies that the country is not prepared to bring to a successful conclusion a war with a first-class power.

If there be any who have any doubt upon this subject, I refer them to the report of a board of officers and civilians made through the War Department to the U. S. Senate in the early part of January, this year. This committee consisted of three Army officers and two civilians appointed by Congress to investigate the subject of the feasibility, desirability, and practicability of the Government manufacturing arms, munitions, and equipment, and certain other allied questions.

This committee made examinations of all the Government arsenals and the principal private plants capable of manufacturing the class of articles required by the Army and Navy, held conferences with heads of leading industrial institutions, and through all practicable sources sought information not only upon the question of whether the Government could manufacture its own arms, munitions, and equipment, but secured accurate data as to the supply of such articles now on hand and the time necessary to secure such supplies from all sources in the case of an emergency.

The report of this committee is in much detail and is very complete.

What I gather from the facts brought out is as follows:

1 The various departments of the Government have on hand at the present time the necessary equipment only for the present regular army and the militia
2 That to properly equip an army of 500,000 men will require six months
3 To equip an army of 1,000,000 men will require one year
4 To equip an army of 2,000,000 men will require 18 months

These are facts and are not open to argument, and the thing for the American people to do is to accept them as facts and to act accordingly. Every military and naval authority allowed to express an opinion publicly has in the most unqualified terms testified in general, and in detail, to the fact that we are pitifully unprepared. If it requires six months to prepare the equipment for an army of 500,000 men, we must start now.

Every engineer ought to post himself as to the actual facts in this connection and use his very best efforts to convince the public in general of the absolute necessity of backing up the Army and Navy in their plans, and should bring such pressure to bear upon Congress that the necessary legislation shall be promptly passed. The great trouble with the people of this country is that they are suffering with that fatal complaint designated by Mr. Homer Lea as "the valor of ignorance."

The average American has the mistaken idea that one American soldier is equal to at least six soldiers of any other nation, when as a matter of fact six American soldiers insufficiently trained and improperly equipped would not be equal to one soldier of any other nation not handicapped by these deficiencies.

In olden times, when men fought hand-to-hand conflicts with various kinds of weapons, the strong and brave could easily conquer the weak, but in modern warfare battles are won by machinery and implements which can be handled only by men trained to a high degree, and personal bravery as well as physical strength go down in defeat when pitted against intelligence and experience armed with modern engines of war.

It is gratifying to be able to say that some very important steps have been taken toward national preparedness, and while up to the present time very little has been actually accomplished in the way of definite and positive results, we can, with some degree of truth, at least say that so far as the plans for mobilization of the great industries of the country for the backing up of the Army and Navy operations are concerned, they have been well prepared and the actual results will quickly follow if the proper coöperation is shown by Congress.

As all of you know, the engineers and chemists of the United States completed and delivered to the Naval Consulting Board on the first of September last, an inventory of the industrial resources of the United States.

As Chairman of the Board for the State of Louisiana I have been in close touch with this work, and I can say that while the information obtained was not as complete as was desired, it was sufficiently accurate to enable the Naval Consulting Board to formulate plans which, when carried out, will accomplish the purpose intended.

I desire to take this opportunity to express to the engineers of Louisiana, 144 of whom volunteered to assist, and did in fact give their time liberally to this work, that I believe it is quite probable we will again be called upon to do other work of this same character; and I hope that our efforts will be clothed with sufficient Governmental authority to require, where necessary, the industrial plants which show the disposition either to withhold information or to take the matter lightly, to answer all questions put up to them, the answers to which will be of value to the Government.

Now, coming down to the definite proposition of what you and I, as engineers, can and should do in the present emergency, it seems to me the first step for us to take is to furnish to the Government full information regarding our qualifications, and the Government should then point out to us the department of the Army or Navy to which our services should be offered.

DISCUSSION

COMMODORE V. S. NELSON. Last August, Congress passed an act establishing a naval reserve corps, which act was approved on the 29th of August, for the purpose of filling out the Navy, of expanding the Navy during time of war.

It seems that a great many people do not understand the difference between the Naval Reserve and the regular Navy. They do not understand what they have to do. When they enlist in the Navy, for instance, they agree to serve for four years. They are sent to sea immediately, and they have to stick out that full time. When they enroll in time of peace, they simply obligate themselves to enter the Navy in time of war. They leave their address with the commandant of the naval district in which they enroll, and they agree to come in for service whenever he calls for them, and he would not call for them unless the President had decided that a state of war, or some other national emergency, existed.

The man enrolling in the Naval Reserve in time of peace is not subject to the laws and regulations of the Navy, except during the time that he is on actual duty—in actual service. While it is the desire of the Navy Department that every man or officer enrolled should serve at least three weeks, they are enrolled for four years, and they are supposed to serve at least three months during that four years. The three months can be served in one year, or three weeks in each year, but in time of peace they are not compelled to serve at all. They simply agree to come in in case of war. But everybody believes that the people who enroll now will have to come in.

It is our object to get in as many men as possible. Of course, if the war lasts a short time, the people who enroll in the Naval Reserve will be allowed to go home and attend to their business, but as long as the war lasts they will be in the Navy, just as much as those people enlisted in the Navy.

Congress has established six classes in the Naval Reserve: The first class is composed of those officers and men who have been honorably discharged from the service, or who have resigned, or who have been discharged for other reasons; but the men who have been discharged must be American citizens. For the last ten or fifteen years nobody has been taken in the Navy except American citizens, but before that, there were some good men in the Navy who were not American citizens, and who received their honorable discharge, but they are not eligible to enroll now. They must be American citizens—take the oath of allegiance to the United States, and pass physical examination before a naval doctor who will be detailed for that duty.

The second class is known as the Naval Reserve—the first-class officers and men who have already served, and the second-class Naval Reserve, and that is composed of officers and men who have had experience at sea. A man to be enrolled as an officer must have had two years' service at sea, as an officer in a lake-going or sea-going vessel, and must pass a certain examination. He must also have had experience at sea, and must pass an examination in order to establish his rating. Officers are enlisted at ages from 21 to 35 years, and the men go in from 18 to 35 years. That is the second class.

The third class is the Naval Auxiliary Reserve. That class is composed of men and officers who are serving on American merchant vessels, who are suitable for naval purposes—naval auxiliaries in time of war, and they must have served, and must be serving, on board of ships of that class. Now, in order to secure a commission as an officer, a man must have, in some way, served on one of those ships, or be serving now, that is, to be enrolled in that class. The intention is not to make those officers enroll from those merchant vessels to serve in the regular navy unless they desire to do so, but to have these men who enroll for the auxiliary service serve in the same kind of ships that they have been serving in before they are enrolled.

The fourth class is what we call the Coast Defense Naval Reserve. This is composed of men who have not necessarily had any experience at sea, but who can be of some service to the Navy, either at sea or on shore. They could serve, for instance, in the coast-defense vessels, in scout vessels and in patrol vessels—the harbor patrol and the outside patrol—or they may serve as radio operators, paymasters, clerks ashore —almost any duty a man can perform will be of use to the Navy and will entitle him to enroll in this class.

Then we have the fifth class, which is composed of men in the flying corps. I don't think there is much flying done around here, but most of them have been taught in the naval schools, and these amateurs who have had experience are eligible as officers.

Then there is the class of volunteers who simply volunteer to come in in case of war. They don't have to come in and serve during peace times. But as we are now at war, everybody ought to be prepared to serve in some capacity or another.

It will take a great many men to man patrol boats, submarine chasers, and all these smaller boats in the coast-defense service. Take, for instance, this New Orleans district, which extends all the way from Tampa to the mouth of the Rio Grande. Patrol boats must be obtained to patrol that whole coast, and men have to be found to man those boats; and what we want to do as much as possible is to get men to enter the service—if they won't enter directly into the Navy, to enter into the reserve navy.

There will be a retainer paid every man and officer. They will get $12 a year, simply a nominal sum. Then, after three months' service, the men and the officers are given provisional appointment for the first time, until they have done three months' service. After that, the officers are examined by a board appointed by the Secretary of the Navy, and they are given the rank which they are qualified to fill, and then they receive a commission from the President and are regularly commissioned in the Naval Reserve. The men are examined in the same way, and rated in the rating which they are able to fill—as machinists, or firemen, or ordinary seamen, or whatever they can do, they are so graded. After they have been confirmed, that is, after they have done the three months' service, both the men and the officers, while they are on active duty, receive the same pay and allowances as the regular officers in the Navy, and the retainer pay in addition.

Now, of course, it is going to be necessary to find men to man all of these patrol boats, mine layers, mine planters, mine sweepers, to sweep for mines and protect the mines we plant ourselves—if it is necessary to plant any—and patrol the harbors, or the river here, and patrol all the coasts. We think that this section of the country certainly ought to provide men to help guard the coast on this side. Of course, New Orleans cannot do it all. All those sections along the coast ought to furnish men to patrol the coast.

MAJOR J. L. SCHLEY. I think the two things which Mr. Lockett brought out which are very, very important are, first, the work organizations, and second, a means of getting before the Government some method of procedure whereby they can get at the members of the organizations who are qualified to do certain kinds of work. Those are the two points which are most important for you to carry away with you. The first of those he mentioned in a way that would lead you to believe that a great many people are not cognizant of the facts as they exist today; that is, that we are unpre-

period, and we are so badly unprepared that we have got to make haste quickly to get it in proper shape. And the first thing, of course, to do is to persuade a man that this is a fact, and I think that probably an engineer takes things more in a matter of fact way and sees them as they exist better, probably, than members of other professions. In his daily work he meets with problems in which he must place on the one side the things which he has to build, to construct, and on the other side he is opposed by the laws of nature; and he knows that in order to accomplish something he must face those problems, and if anything goes wrong, the laws of nature, he knows, will come into play. For that reason, he brushes aside the unessentials, and usually arrives at a solution of the problem. Therefore, the engineers throughout the country have probably weighed the question on one side and the other, and have probably come to a conclusion in their own minds that something should be done, and each man has probably reached a conclusion more or less definitely as to what should be done. So I think the first point to be emphasized is that of convincing people who have not looked at things from our point of view of the actual conditions, and that something must be done and done promptly.

The second point of great value is to formulate the method of making it possible for the Government, as you might say, to put its finger on the individual and assign him to the work of a mechanic, or any other position to which he is especially adapted.

If each engineer should write personally to any one of the Government offices, for instance, the office of the Chief of Engineers, you can imagine what a mass of correspondence would be presented, and what a problem it would be to attempt to get anywhere with it; whereas, if an organization of this kind would, through a committee, get in touch with some one and present the names of men who are willing to do something in their particular lines, it would be very much more simple for the Department to assign some work to each group of men, or to each institution, or each organization. In other words, it is the difference between an organization and a mob. In a mob it is difficult to get hold of the individual, whereas in the well-organized army, or well-organized industry, through the different means of control and supervision, each man is assigned to the work which he can do best, and the results are to gather together to a common end, and I think that through your associations forming organizations for that purpose you can get in touch with the Government and the Government can get in touch with the individuals.

Captain H. A. Drum. I appreciate very much the honor of being given this opportunity to carry out a duty which has been assigned to me. General Pershing has sent me to this part of his department in order to interest you in training camps. The training camp, as you are well aware, started in New York, about two years ago, through the patriotism and the individual realization of a national duty by a number of men in New York. It came to them suddenly that there was going to be a time when they would have to respond to their individual duty to the nation. They felt that when that time arrived they wanted to know something about the profession of soldiery. A few of them, about four hundred, gathered together and asked the regular Army to give them some of this training. That was based first on patriotism, second on an individual realization of a national duty.

Before taking up the details of the camp, I want to bring home one or two little points to you about the citizens' training. The President, in his message of December, 1914, stated that this country, in time of peril, should not depend on a standing army, or on a reserve army, but should depend upon a citizenry trained and accustomed to arms. If any of you will go back into our past history and study it carefully, you will find that has been our policy. If you go into the history of Europe and of other nations, you will find that has been the policy of the European nations. They have depended upon a citizenry accustomed to arms. This means a citizenry trained for and accustomed to the duty of defending the country. It cannot have any other meaning in a country like ours, in a country that is governed for the people and by the people. I don't see anything that can be more democratic than that the citizenry should defend the nation.

With these two thoughts in your minds, I would like you to think what your duty as a citizen of the nation is. I believe, first of all, your duty is to have adopted a policy of defending the nation for the people, of the people, and by the people. Second, if you agree to that, I think you should have a policy of having your Government train you for the defense of the nation. If one is true, the other is true also.

Certain civilians with whom I have talked about universal service have seemed to have the impression that the young man entered the service at about eighteen and stayed there until he was forty-five—spent his whole life in military service. That is not so. The General Staff Bill provides for one period of eleven months and three periods of two weeks each, practically a total of one year of actual service, except service in time of war.

This is nothing new to us, this conscription, this actual service by compulsion. In the Civil War we had it. The Confederacy adopted it in the first year of the war, and the North adopted it in 1862. If you analyze what universal service means, it is nothing more than producing a citizen army instead of a standing army. It is nothing more than having an army to defend your nation whose interests are peace, whose hopes are peace, and whose vote will be for peace as long as, in their judgment, the nation's honor and duty are safeguarded. It seems to me that it is the most democratic thing that you could have. It seems to me that it brings the rich and poor, capital and labor, on the same level in the defense of the nation. It brings them down to a common level of duty, and is the production of an army of the people, for the people, and by the people.

As to the past, we have never as a nation been prepared for any war, principally because the people of the nation have never made it their business to look into it. We are a democracy, and the basis of all democracy, the essence of democracy, is that movements shall start from the bottom and work up; that is, they will start from the people; whereas in an autocracy it is the opposite; they start from the top and are imposed on the nation below. The United States, except in one case, has never carried a war to a conclusion in which it has not had to use at least two men to the enemy's one. In the Revolutionary War we employed, all told, 395,000 men. The enemy had a total in this country of 150,000. In the War of 1812 we passed through our ranks 575,000 men; the total force of the enemy in this country was 67,000. In the Mexican War we had 140,000 men; the total Mexican force was 46,000. In the Civil War the North employed a little over two and a half millions, and the South a million. It seems to me that the marked difference in the numbers and the success on both sides in that war was due to the early adoption of conscription by the South. The only exception was the Spanish-American War, in which we had under

arms 280,000 men. There were, all told, in the Spanish forces—not in this country, but in the whole forces—not over 220,000.

If you will look back in the history of the Navy you will see that the Navy has been successful all through. It has had very few reverses, first and foremost because it has been an absolute Federal force. It has nothing to do with the forty-eight subordinate Governments. Second, it has had practically the same officers, the same skilled men in peace as in war. The expansion of the Navy for war is generally from the bottom.

The fine, large preparedness movement all over this country stirred people in an industrial way, worked up mobilization of tools, materials and all that, but it lacked one thing. Have you heard of any organization being formed for the mobilization of the fighting man-power of the country? Have you joined any organization for producing the fighting man-power of the country? There is where we have fallen down. It certainly is essential that we work on the production of munitions and mobilization of the industrial forces of our country. But there is one essential element and that is the fighting man.

We are now called upon to organize an army of a million men, and will need from 30,000 to 40,000 officers. We have today in the army a little over 8000. Where are we going to get the others? You cannot go ahead and organize an army without first having officers, and you cannot pick officers off the trees any more than you can pick engineers off the trees. You have to have men who have the fundamentals of education, whose brains have been developed in such a way that they are receptive and can pick up something new, work on it and get something tangible out of it. The point has been brought up here as to what the engineer can do. It is not a question of all of you staying home and working up the industries—the majority of you should get into that society of the fighting man-power and prepare to be officers. And the means for training men to be officers are these training camps. So the regular Army has put itself at the disposal of the citizens, to give you everything there is in us, and try to make you into the best officers you can be in the short time that we have.

Now, I claim that that disposition on our part throws a duty on you. Your duty is to come or to send some one to us, and we give you everything we have if you will come there to receive the training. These camps are primarily for the infantry. After that, they are for the training of every other branch of the service—cavalry, artillery, signal corps, and engineer corps. The medical corps have their training in these camps too. So if you want to start in the same line in which you have started your civil profession you can get your training in these military camps as a starter. The camps are free. There is no expense about them. The Government furnishes your transportation from your home to the camp, furnishes your food and uniform and equipment while at the camp. The only requirement is that you will deposit, on arrival at the camp, $10 as guarantee for the return of the equipment that the Government furnishes you. You are authorized to buy your uniform, according to the regulation standards, and the Government will reimburse you at the rate of one-third of the cost for each camp that you attend. The uniform will cost you about $15. One camp lasts for thirty days. The only obligation that you have to take upon yourself is an oath of enrollment, that you will serve the President of the United States and the officers over you during the thirty days of instruction at the camp. The camp which you go to is designated in the oath. After those thirty days are over, you are through.

Lieutenant E. S. Moses. A few days ago Mr. Lockett was talking to Commodore Nelson, and he was very anxious to find some definite points that the engineers could start on, for work. So I wrote a few notes for Mr. Lockett, and I didn't expect to speak tonight; I thought he would bring that out. The first point was: start at once intensive training for young men who are ready to go ahead with actual preparedness but do not wish to bind themselves until they have maturely determined the work for which they are best fitted.

The second point was this: study facilities for a motor-boat repair base at the mouth of the river and the personnel for same. Also a supply system for boats operating at the mouth of the river—fuel, food and stores, as well as plans for medical attention. No doubt the Quarantine Station can furnish the personnel, but the Red Cross can probably aid with special equipment or nurses. Accommodations may have to be enlarged and provision made for taking care of people suffering from exposure in open boats.

I understand it will take several motor boats to form a scouting ring around the mouth of the river, and if there is anything sunk out there we will need large facilities for repair work and hospital work, and also in order to keep a steady chain of supplies going.

Third, thoroughly canvass aero resources. If practicable, have the Country Club finance as many aeroplane instructors as can be obtained and have as many members as possible qualify as air pilots. My suggestion of the Country Club is only for illustration, but I consider it practical for some group of wealthy men or women to start such a movement, and its immense importance is obvious.

You all know the relation of supply and demand of people who can operate aeroplanes and man aeroplanes. We can make the aeroplanes, but we cannot make our pilots.

Now, the next point that is particularly interesting to engineers—and to any wholesale dealers and manufacturers here—is to establish and maintain a perpetual stock-card system, showing the material actually on hand and ready for immediate delivery. This is a large order, but its benefit to the city under normal conditions would be so great that it is well worth while to press the matter in the present emergency, both as a patriotic measure and as an economical advantage to the city, so that the local dealers will get their share of war business. The Association of Commerce should be able to handle this.

The next point is developing a transportation system for immediate delivery of material. At the time of writing, a case is brought to my attention of material ordered from the stock of a local firm seven days ago, which is yet undelivered. The large volume of business now being done at the Naval Station would seem to justify the city dealers in coöperating by having a large motor truck leave the corner of Canal and Camp Streets at 9:00 a. m. and 1 p. m. daily, call at each of the dealers subscribing to its maintenance, and thence to the Navy Yard. This is only a suggestion of one of the thousands of details of rapid transportation which must be solved now that we are at war. I suggest the appointment of local transportation committees to devise some means of transporting stores and men from one place to another.

The concluding paragraph in my letter to Mr. Lockett is this: "I presume your Committee has gone very thoroughly into the question of increasing the production capacity of the

plants now in existence. I trust that you have gone into the question of assignment to individual plants constant production repeat orders in order to reduce the variety of work in existing plants. An efficient organization should be formed to control output so that there will not be an excess of one product and a scarcity of another equally important. I doubt if it will be practicable to exercise the necessary authority over individual plants by any private combination, but much advance work can be done to plan a scheme of control should it become necessary for the Government to take over all plants. The question of standardizing gages, fixtures, etc., comes under this general head, and if it is at all practicable I think it would be well worth while to call in the service of an efficiency engineer to make a general industrial survey."

General A. Perilliat. The talks we have had this evening from gentlemen who are well posted in their professions in the art of war have shown how much is to be done, and I fear how much is to be done very quickly, and at once. All of us knew that there was a gigantic work in front of us, but these gentlemen who belong to the profession of the soldier have thrown a little additional light on how much has to be done by this nation and this country to meet the crisis now on our hands. It goes without saying that every man in this room, from a sense of patriotism, from his love of his country, is going to do everything in his power to help out the situation.

We engineers are going to give the best that there is in us. Mr. Lockett has outlined very wisely and with a great deal of thought what we might do. Major Moore has stated that, after all, the man on the front has to be a soldier. He has to know what to do with the things that are given to him to fight with. Sir Douglas Haig has said that for every man on the firing line it took five men to equip him and to keep him furnished with supplies, munitions, quartermasters, commissary department, things which are needed for him to fight successfully.

We are about to raise an army of one million men. It will become necessary, then, to select various kinds of men. It will be necessary to see that men do not go on the firing line when they are better equipped to remain behind the firing line and do the work of these five men who are necessary to prepare and furnish the fighting man with what is necessary to accomplish or win his fight. I am told that in England, at the beginning of this war, thousands and tens of thousands of men volunteered and went to the firing line, and then it was found that they were better fitted, better suited, to be at home, preparing munitions and supplies and supplying the army with that which was needed to fight. I think I see a little daylight through the various talks which we have had before us this evening. The only dark spot, and that is very dark, indeed, is time. It takes time to do things, to accomplish things.

The work of selection and making a census of the industries which would be useful and necessary in the conduct of war has been very ably performed, in this case, by Mr. Lockett and his committee. The Government at Washington has a very complete record of the plants and factories that can be converted into the manufacture of that equipment which is necessary to an army. Something, however, is very necessary in addition to this, and I think Major Moore has touched upon it. Mr. Lockett has also touched upon it. We want a census of men who can do things, and we want to know what they can do. We want to know the name, the address, the age, the capacity of every civil engineer, of every mechanical engineer, of every chemist, of every mechanic, of every electrician. We want that so that when the call comes the right men will find their right places and their proper places without the necessity of first sending them to the wrong place and then bringing them back to do the work for which they are best fitted.

I think that the societies of engineers, both mechanical and civil, should, by the nature of their profession, come in touch with technical men of all kinds, that our Society could easily, under the direction of a committee, of its president, resolve itself into committees, not only in the city, but throughout the State, and make a census. It is quite possible that the Government has already issued instructions for this. If the Government has issued instructions, we can place ourselves subject to the officers of the United States Army or of the Government, to work in that direction. In that way we can be immediately useful. Upon our shoulders, or upon the shoulders, perhaps, of the older men of our profession, will devolve the duty of finding, of equipping, of directing the efforts of these five other men who are necessary to supply the one man on the firing line. The duty of organization of the work behind the firing line is going to be an immense undertaking, and the training of engineers, the training which we have received in our profession, I believe, renders us especially fitted to perform this work, under the direction, of course, of the military heads, who must command and direct everything.

Professor C. S. Williamson. I realize perfectly well that men must be had, and that trained men must be had, officers must be had, patrols must be maintained on our coasts, patrols must be maintained on land at certain points, but back of all of that is the serious side, that we must furnish the material which has been spoken of here tonight, with which these men who patrol may actually carry out the patrol. Now, we have a survey which has been spoken of also, that was made by the Naval Consulting Board, through its various State organizations, in which 144 of us have participated in this State, and we have that on file in Washington, as a fairly complete survey; but even with that there is yet a serious consideration that some of those materials in that survey are not inexhaustible in the United States. It may become necessary for us as engineers to be called into service in the actual manufacturing of certain supplies very much more intensively than we have spoken of tonight.

I don't think this is the time to lay bare any actual facts and figures, but there are some commodities which we do not produce in the United States which are absolutely essential to either land or naval warfare. There are certain commodities which are at hand and can be readily put into use. I know one plant in this state that has a certain by-product that goes into the sewers, that with a very small equipment could be turned into one of the essentials for making cordite. I know one other concern here that could turn another by-product to a useful purpose which is not listed in our survey—and was not so stated. These are by-products which have not been actually thought of as being turned into use.

Now, the point I want to bring out is this: there are certain manufacturing plants that could be turned to immediate use if it became necessary. We have not a sugarhouse in the State of Louisiana that could not be turned to the manufacture of materials to be used in making explosives. We have one certain product that could be made in our sugarhouses here. We have a second product which could be made in the sugarhouse which is absolutely essential to the manufacture of explosives. We have here in Louisiana a natural resource for the manufacture of explosives which has not been exploited, which I believe could be put up and operated on fairly short notice, a certain product which could be manufactured here.

TENTATIVE DRAFT OF A CODE OF SAFETY STANDARDS FOR POWER-TRANSMISSION MACHINERY[1]

Rules and Requirements for the Protection of Industrial Workers from Hazards Commonly Presented by Mechanical Equipment Used for Transmitting and Distributing Power from the Prime Movers to the Various Power-Utilizing Machines, Tools and Devices

NOTE—The use of properly designed, constructed and installed individual motor-driven equipment with electrical power distribution not only eliminates many of the hazards demanding this Code, but also gives an uninterrupted distribution of natural and artificial light, and a greater flexibility and range of speeds than is possible with mechanical power-distributing systems.

The following specifications describe standard guards for all power-transmission equipment hereinafter mentioned, and apply to all main shafting, jack shafting, drive shafting and countershafting, and their belts and other attachments up to but not including belts actually driving machines.[2]

2 *Class A Guards:* If the clearance between the guard and the guarded part is less than five (5) inches, a metal guarding material that will not admit objects larger than one-half ($\frac{1}{2}$) inch in diameter, strong enough to withstand loads to which it may be subjected, durable enough to withstand ordinary wear and tear, substantially fabricated and erected, and free from sharp points and edges.

3 *Class B Guards:* If the clearance between the guard and the guarded part is five (5) inches or more, a metal guarding material that will not admit objects larger than two (2) inches in diameter, strong enough to withstand loads to which it may be subjected, durable enough to withstand ordinary wear and tear, substantially fabricated and erected, and free from sharp points and edges.

4 *Handrails:* If the clearance between the guard and the guarded part is fifteen (15) inches or more (measured horizontally from extreme parts within six (6) feet of floor), a handrail forty-two (42) inches in height with at least one intermediate rail, supported at least every eight (8) feet, substantially fabricated and erected, with no sharp points or edges.

5 If constructed of pipe, the rails and posts shall be at least equal in strength to one and one-fourth (1¼)-inch standard-weight pipe.

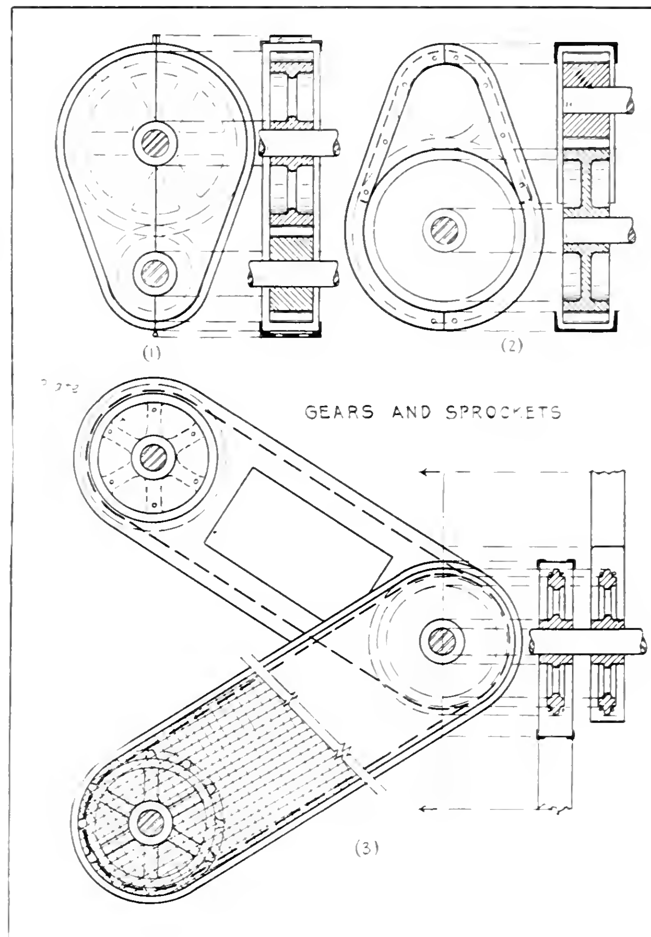
6 If constructed of structural metal, the rails and posts shall be at least equal in strength to two by two by one-fourth (2 x 2 x ¼)-inch angles.

7 If constructed of wood, the top rail shall be two inches by four inches (2 x 4), the center rail one inch by four inches (1 x 4), and the posts four inches by four inches (4 x 4), all straight-grained lumber dressed on four sides, or other construction of equal strength.

8 *Toe Boards.* When power-transmission equipment extends through floors or into pits, Class A and B guards shall extend to the floors, or toe boards six (6) inches in height shall be provided around the floor opening in addition to standard handrails. (See Figs. 6, 7, 11, 14, 30, 31, 34, 48.)

9 *Sanitary Bases.* Class A and B guards, for power-transmission equipment not extending through floors, shall enclose exposed sides to two (2) inches below the bottom of the lowest moving part when the clearance between that part and the floor is less than eight (8) inches; or when the clearance between the lowest moving part and the floor is eight (8) inches or more, the guards shall be closed on the bottom, or extended on all sides down to six (6) inches above the floor. (See Figs. 15, 26, 36-40, 42, 43, 49-54.)

10 *Gears and Sprockets.* All power-driven gears and sprockets shall be completely enclosed on exposed sides with standard guards as specified in Class A or B, except in cases where the design and operation of the parts to be guarded make a complete enclosure clearly impractical: in which case the face of the gears or sprockets shall be covered with a band guard surrounding all exposed teeth, with flanges on both sides extending inward beyond the roots of the teeth, and there shall be a continuous smooth web cast or fitted between the hubs and rims of the gears or sprockets. (See Figs. 1, 2, 3.)



FIGS. 1 TO 3 GUARDS FOR GEARS AND SPROCKETS

11 *Vertical and Inclined Belts, Ropes, Chains.* All vertical and inclined belts, ropes and chains used for transmitting or

[1] Compiled and presented by Carl M. Hansen and Rufus W. Hicks, under the direction and with the approval of the Committee on Health and Safety, National Association of Manufacturers. Submitted by the Sub-Committee on the Protection of Industrial Workers for the consideration of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

[2] Belts actually driving machines will be considered "machine belts," and therefore a subject for machine codes.

Presented at the Spring Meeting, Cincinnati, Ohio, May 1917, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

distributing power (except belts traveling less than 120 feet per minute, or transmitting so little power that accidental contact therewith could cause no accident) shall be provided with standard guards as specified in Class A or B, six (6) feet high on exposed sides, or on exposed sides and top, or with a standard handrail on exposed sides. (See Figs. 4 to 46, inclusive.)

12 *Horizontal Belts, Ropes, Chains.* All horizontal belts, ropes and chains used for transmitting or distributing power (except belts traveling less than 120 feet per minute, or transmitting so little power that accidental contact therewith could cause no accident) shall be guarded as follows:

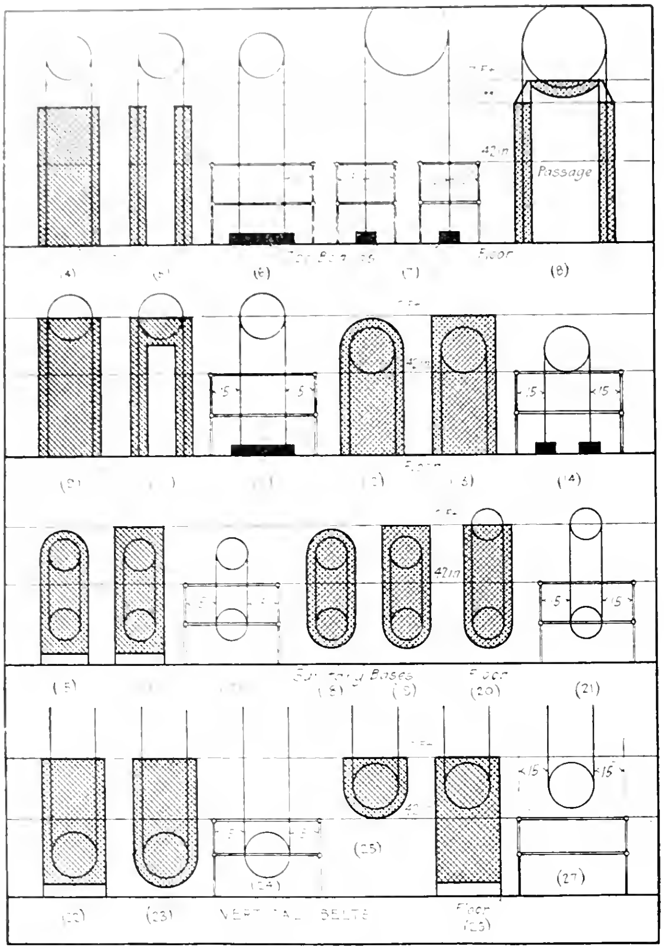
13 *Low Belts.* If the upper part of the belt is lower than

and bottom, or with standard handrail on exposed sides. (See Figs. 59, 60.)

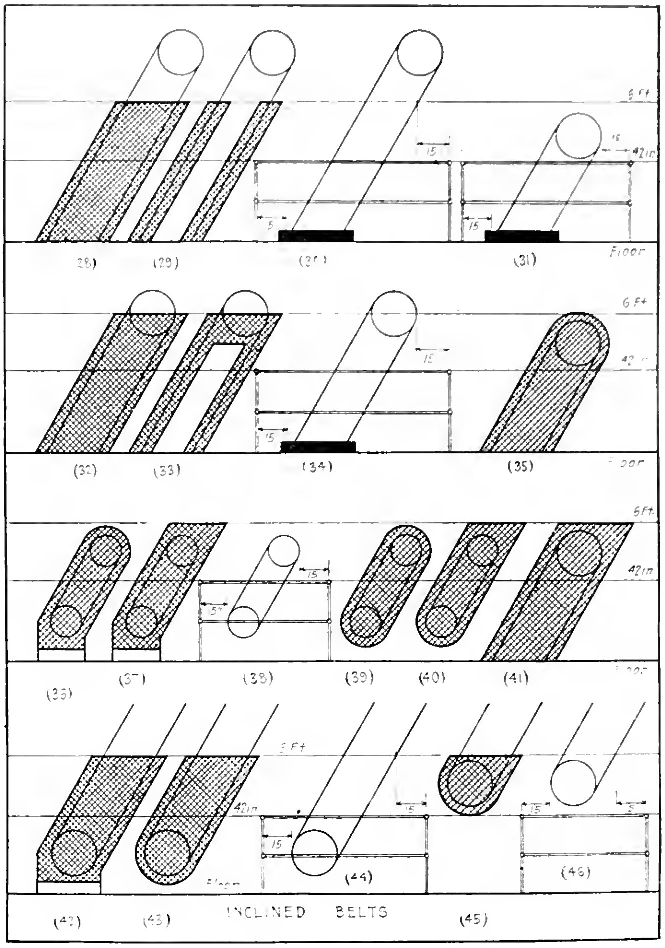
16 *Belts over Driveways.* Where a horizontal belt is located over a driveway or passageway, the highest floor of any wagon or truck passing beneath the belt shall be considered a working platform.

17 *Belt Fasteners.* All belts not provided with guards as specified in Class A or B and within seven (7) feet of the floor or working platform shall be free from metal lacings and metal fasteners.

18 *Belt Shifters.* Belt shifters shall be provided for all tight- and loose-pulley belts, and shall be so designed and constructed that ordinary vibrations or accidental contact will not



Figs. 4 to 27 Guards for Vertical Belts



Figs. 28 to 46 Guards for Inclined Belts

six (6) feet above the floor or working platform, it shall be provided with standard guards specified in Class A or B, six (6) feet high on exposed sides, or on exposed sides and top, or with a standard handrail on exposed sides. (See Figs. 47-50.)

14 *Medium Belts.* If the upper part of the belt is higher than six (6) feet above the floor or working platform and the lower part of the belt is lower than six (6) feet above the floor or working platform, it shall be provided with standard guards as specified in Class A or B, six (6) feet high on exposed sides, or with a standard handrail on exposed sides. (See Figs. 51-58.)

15 *High Belts.* If the lower part of the belt is higher than six (6) feet above the floor or working platform and lower than seven (7) feet above the floor, it shall be provided with standard guards as specified in Class A or B, on exposed sides

alter the set position, and shall have a controlling handle conveniently located. (See Figs. 61-63.)

19 *Pulleys.* Pulleys belted from above or from the side in such a way as to allow passage beneath the pulley, and within seven (7) feet of the floor or working platform and not completely enclosed by standard belt guards or handrails, shall be guarded to the top of the pulley or to a height of seven (7) feet above the floor or working platform on exposed sides and beneath by guards as specified in Class A or B, or be enclosed on exposed sides by standard handrails. (See Figs. 64-67.)

20 *Bearing Clearance.* The clearance on shafting between pulleys and bearings or between pulleys and fixed objects shall be not less than thirty-six (36) inches and wider than the belt, or the pulleys shall be guarded on the near side with stationary guards as specified in Class A or B, and all revolving ob-

jects in the clearance shall be smooth, cylindrical and concentric with shafting. (See Figs. 68-73.)

21 *Belt Clearance.* The clearance on shafting between pulleys and pulleys, collars, couplings or other revolving attachments shall be wider than the widest belt used, or the pulleys shall have flanges or guards to prevent the belt from dropping into the clearance. (See Figs. 68-73.)

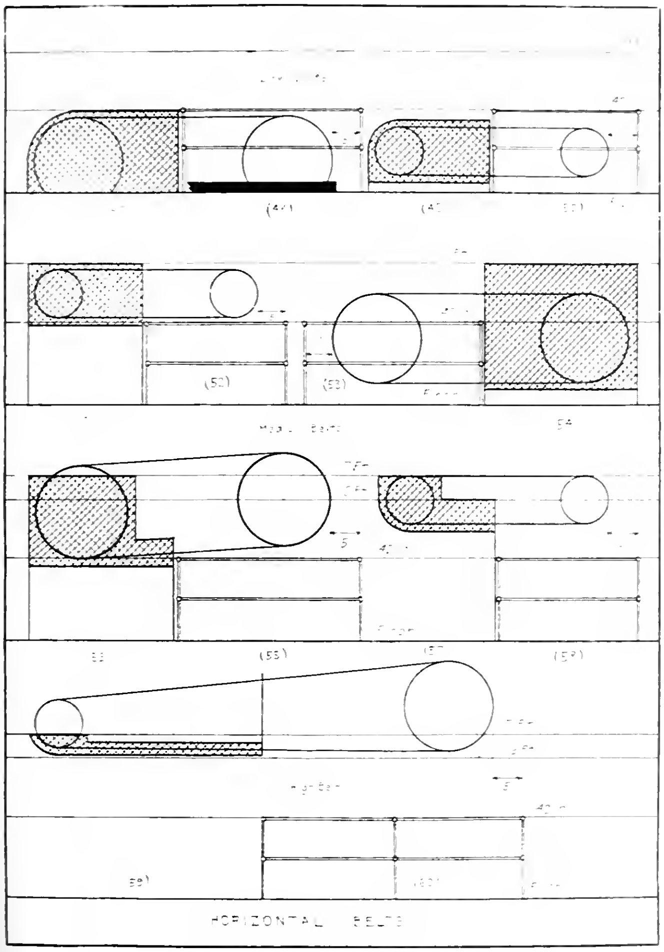
22 *Abandoned Pulleys.* Pulleys without belts shall be guarded as though belted, or removed from revolving shafts.

23 *Clutches.* Friction clutches, jaw clutches and compression clutches within seven (7) feet of the floor or working platform or within thirty-six (36) inches of a bearing shall have their operating mechanism completely enclosed in stationary guards as specified in Class A or B, or in smooth, concentric revolving guards of solid construction with no projecting parts or attachments.

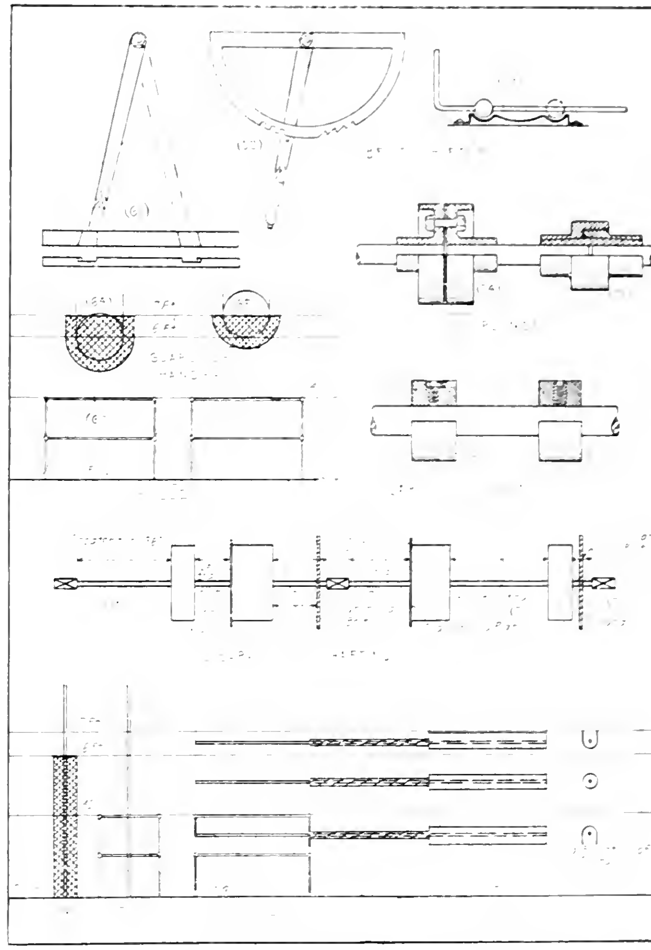
24 *Couplings.* All couplings within seven (7) feet of the floor or working platform or within thirty-six (36) inches of a bearing shall be guarded as follows:

25 *Rigid Couplings.* Sleeve couplings and flange couplings shall be cylindrical and concentric with the shafting and with no parts or attachments projecting beyond the largest periphery of the coupling or its projecting flanges. (See Figs. 74, 75.)

26 *Flexible Couplings.* Flexible and universal couplings shall be completely enclosed in standard stationary guards as specified in Class A or B, or in smooth concentric revolving guards of solid construction.



Figs. 47 to 60 Guards for Horizontal Belts



Figs. 61 to 82 G[illegible]

27 *Clamp Couplings.* Clamp couplings and makeshift devices of irregular shape or unknown strength are prohibited on power-driven shafting.

28 *Collars.* Assembled collars shall be smooth, cylindrical and concentric with shafting, with no projecting parts or attachments. (See Figs. 76, 77.)

29 *Set Screws.* All set screws in revolving parts not enclosed by standard guards as specified in Class A or B shall be flush with or countersunk below the periphery of the part retaining the set screws. (See Figs. 76, 77.)

30 *Keys.* All keys or keyways in revolving shafting not enclosed by standard guards as specified in Class A or B shall be made flush with the end and periphery of the shaft or enclosed by smooth, cylindrical, concentric guards.

31 *Vertical Shafting.* Vertical shafting with or without collars, couplings, clutches, pulleys, or other attachments shall be enclosed on exposed sides with standard guards as specified in Class A or B to a height of six (6) feet above the floor or working platform, or with a standard hand rail. (See Figs. 78, 79.)

32 *Horizontal Shafting.* Horizontal shafting with or without collars, couplings, clutches, pulleys, or other attachments, including dead ends, within seven (7) feet of the floor or working platform, shall be enclosed on all exposed sides with standard guards as specified in Class A or B or with standard hand-rail, or with freely revolving tubing. (See Figs. 80-82.)

33 *Shafting over Driveways.* Where horizontal shafting is

erected over driveways or passageways, the highest floor of a wagon or truck passing beneath, the flatting shall be considered a working platform.

34 *Emergency Stop Stations.* A station or stations shall be provided in each room, story or department to stop immediately all power-transmission equipment therein. Such station or stations shall be properly marked and easily accessible and provided with means for locking in "stop" position.

35 *Bearings.* Where possible, bearings shall be of a self-oiling type with reservoir capacities for at least 24 hours' running or shall have other methods of oiling which do not bring the oiler in the danger zone, and shall have necessary drip cups and pans securely fastened in position.

36 *Lubrication.* Oiling which brings the oiler in a danger zone shall be done only by an authorized person, and while the machinery is not in motion.

37 *Oiler's Clothes.* The oiler must not wear loose or flowing clothing.

38 *Oiler's Lock.* The oiler shall be provided with a lock and key or with a key to the locks at the emergency stop stations, and with a warning sign to display at the stations when at work on machinery controlled by that station. He shall be required to lock the station in a "stop" position and display the sign before going to work, and unlock and remove the sign when the work is completed and all men have left dangerous places.

39 *Starting Signals.* Ample notice should be given by means of an effective alarm or signal in all departments before power-transmission equipment is started.

40 *Inspection.* All power-transmission equipment should be carefully inspected at frequent and regular intervals by foremen or authorized inspectors, and defective equipment should be reported for repair and records kept of inspections.

41 *Repairs and Adjustments.* Repairs and adjustments to power-transmission equipment or guards therefor shall be made only when the power is cut off from that equipment, and guards shall be replaced in protective position before the power is cut on.

42 *Removing Guards.* Guards installed in accordance with this Code shall not be removed or rendered ineffective.

Respectfully submitted.

John Price Jackson, *Chairman* John H. Barr Melville W. Mix M. W. Alexander Wm. P. Eales G. R. Olshausen John W. Upp William A. Viall Carl M. Hansen	Sub-Committee on the Protection of Industrial Workers

Corrosion Research Laboratory in England

A new corrosion research laboratory has been equipped from a grant from the Department of Scientific and Industrial Research in England at Brighton, and the Royal School of Mines, with the purpose of prosecuting further the investigation begun by Capt. G. B. Bengough and Dr. O. F. Hudson under the auspices of the Corrosion Research Committee.

From explanations given by Capt. Bengough to some technical journalists it appears that at the present time the work is being concentrated on the causes of corrosion in condenser tubes. Copper-zinc tubes are being subjected to investigation chiefly with the view of determining the causes that lead to dezincification, which is the beginning of many corrosive troubles. Ordinary 70:30 tubes were exhibited which showed dezincification arising from spills in the wall, the presence of oxide in the metal annealing at wrong temperatures, improper pickling, and the presence of swarf holes. Capt. Bengough also showed a sample made from an alloy which was prepared in such a way that an oxide-free tube was drawn from it, another which was 90 per cent copper and 10 per cent nickel, and a third of 92.5 per cent copper and 7.5 per cent aluminum. These special tubes were under experimental tests and were kept under close observation and extremely valuable information was expected from the investigation. It was known that 98:2 copper-nickel was unsuitable for condenser work; likewise an 80:20 alloy, since they failed in the laboratory to attack a 90:10 tube and intended to transfer that experiment shortly to Brighton.

Among other things which, according to *Page's Engineering Weekly* of April 20, 1917, were shown by Capt. Bengough to the technical journalists, was an optical instrument designed for determining the position of every discernible surface flow in each tube that is put into the experimental condenser; also an annealing furnace and the sea-water tanks in which the preliminary corrosion tests are made.

New Malleable Castings Method

According to the *Iron Age,* April 19, 1917, a new method of making malleable-iron castings, doing away with the air furnace, will be used in the plant now being built by the National Malleable Castings Company, Cleveland. The metal will be melted in a cupola and a portion of the melted charge, depending on the amount of carbon and other impurities to be removed (usually about one-fifth of the total), will then be run into a side-blow bessemer converter, in which the carbon, manganese and silicon will be partially or wholly blown out. The treated metal is then to be combined in a ladle with the remainder of the metal from the cupola, and the charge transferred to an electric furnace in which the refinement of the metal will be completed. If such complete refinement is not required the metal may be cast without being subjected to the final refinement in the electric furnace. The melting equipment will consist of four 72-in. Whiting cupolas, bessemer converters built by the company, and four 6-ton Heroult electric furnaces.

The method of pouring will also be a radical departure from the usual practice. Instead of pouring directly into small ladles, the metal will be poured from the electric furnaces into ladles of 12,000 to 14,000 lb. capacity and carried a considerable distance with traveling cranes and then poured into small ladles. From the latter the metal will be poured into the molds. This practice will necessitate the installation of a greater number of cranes than would otherwise be required. Twelve or fourteen traveling cranes, up to 20 tons capacity, will be provided. The plant is expected to be ready for operation about January 1, 1918.

The seventh Edison Medal, awarded to Nikola Tesla for meritorious achievements in his early original work in polyphase and high-frequency electric currents, was presented to him at the annual meeting of the American Institute of Electrical Engineers in the Auditorium of the Engineering Societies Building, New York, on the evening of May 18. President H. W. Buck presided and addresses were made by Dr. A. E. Kennelly, Chairman of the Edison Medal committee, Charles A. Terry, and B. A. Behrend, Mem.Am.Soc.M.E.

REVISION OF BOILER CODE

The Council of the Society has directed that the proposed changes in the Boiler Code be published in The Journal with the request that any desired discussion on the proposed changes be mailed to the Boiler Code Committee for consideration. These proposed changes embody suggestions made at the meetings held at the Society headquarters December 8 and 9, 1916, at which all those interested were invited to attend and participate in the discussions.

At the last meeting of the Boiler Code Committee it was decided to publish all revisions so far agreed on by the Committee. There are other revisions which will be published later on, with the request that they also be discussed. This will make it possible for any one to discuss the proposed revisions before they are brought to the final form and presented to the Council of the Society for approval.

Note. *Only such portions of the Code as are subject to revision are here presented, with references to their proper paragraph numbers.*

PAGE 8

Par. 12. Change Par. 12 to read as follows:

12 Cast iron shall not be used for nozzles or flanges attached directly to the boiler at any pressure or temperature. Cast iron shall not be used for boiler and superheater mountings such as connecting pipes, fittings, valves and their bonnets, for steam temperatures of over 450 deg. fahr.

Par. 13. Change Par. 13 to read as follows:

13 Water-leg and door-frame rings of vertical fire-tube boilers, and of locomotive and other type boilers, shall be of wrought iron or steel, or cast steel of Class A or Class B grade, as designated in the Specifications for Steel Castings. The OG or other flanged construction may be used as a substitute in any case.

PAGE 9

Par. 19. Change Par. 19 to read as follows:

19 The minimum thickness of butt straps shall be given as in Table 1. Intermediate values shall be determined by interpolation. For plate thicknesses exceeding $1\frac{1}{4}$ in., the thickness of the butt straps shall be not less than three-quarters of the thickness of the plate.

PAGE 11

Par. 25. Make the following changes in Par. 25:

Strike out the word "Copper" in the table, and under "Firebox" strike out "not over 0.0[illegible] per cent."

PAGE [illegible]

Par. 123. Make the following changes in Par. 123:

Change the percentage of yield point from 0.6 tensile strength to 0.5.

PAGE [illegible]

Par. 141. Make the following change in Par. 141:

Change the percentage of yield point from 0.6 tensile strength to read 0.5 tens. str.

PAGE 40

Par. 164. Make the following change in Par. 164:

In Par. 164 after the word "knobbled" insert a comma.

Par. 167. Change Par. 167 to read as follows:

167 *Flange Test.* *a* For tubes not more than 6 in. diameter a test specimen not less than 4 in. in length shall have a flange turned over at right angles to the body of the tube without showing cracks or flaws. This flange as measured from the outside of the tube shall have a width of from $\frac{1}{8}$ in. to $\frac{1}{2}$ in. The width between these limits to be not less than 10 per cent of the outside diameter of the tube. For tubes more than 6 in. diameter the flange test is not required.

b In making the flange test, the flaring tool and die block as shown in Fig. 7, may be used.

PAGE 41

Par. 169. Change Par. 169 to read as follows:

169 *Hydrostatic Tests.* Tubes under 5 in. in diameter shall stand an internal hydrostatic pressure of 1000 lb. per sq. in. and tubes 5 in. in diameter or over, an internal hydrostatic pressure of 800 lb. per sq. in., provided that the fibre stress does not exceed 16,000 lb. per sq. in. in which case the test pressure shall be determined by the following formula

$$P = \frac{32{,}000}{D} \times t$$

where t is the wall thickness in inches; D is the inside diameter in inches. Lapwelded tubes shall be struck near both ends, while under the test pressure, with a 2 lb. steel hand hammer, the blow to be equivalent to 2 lb. falling 2 ft.

PAGE 42

Par. 174. Change Par. 174 to read as follows:

174 *Workmanship.* Finished tubes $3\frac{1}{2}$ in. or under in outside diameter shall be circular within 0.02 in. and the mean outside diameter shall not vary more than 0.015 in. from the size ordered. For tubes over $3\frac{1}{2}$ in. in outside diameter, these variations shall not exceed 0.5 per cent of the outside diameter. All tubes shall be carefully gaged with a B.W.G. gage and shall not be less than the gage specified. Tubes on which the standard slot gage, specified, will go on tightly at the thinnest point, will be accepted. The length shall not be less, but may be 0.125 in. more than that ordered.

PAGE 44

Par. 184. Change Par. 184 to read as follows:

184 *Circumferential Joints.* *a* The strength of circumferential joints of boilers, the heads of which are not stayed by tubes or through braces, shall be at least [illegible] per cent of that required for the longitudinal joints of the same structure.

b When 50 per cent or more of the load which would act on an unstayed solid head of the same diameter as the shell, is relieved by the effect of tubes or through stays in consequence of the reduction of the area acted on by the pressure and the holding power of the tubes and stays, the strength of the circumferential joints in the shell shall be at least 35 per cent of that required for the longitudinal joints.

c In circumferential joints of horizontal return tubular boilers the shearing strength of the rivets shall be not less than 50 per cent of the full strength of the plate corresponding to the thickness at the joint.

PAGE 45

PAR. 186. CHANGE PAR. 186 TO READ AS FOLLOWS:

186 *Welded Joints.* The ultimate strength of a joint which has been properly welded by the forging process, shall be taken as 28,500 lb. per sq. in., with steel plates having a range in tensile strength of 47,000 to 55,000 lb. per sq. in. Autogenous welding may be used in boilers in cases where the strain is carried by other construction which conforms to the requirements of the Code and where the safety of the structure is not dependent upon the strength of the weld. Autogenous welding shall not be used in place of caulking or girth joints.

PAR. 187. CHANGE PAR. 187 TO READ AS FOLLOWS:

187 *Riveted Longitudinal Joints.* The riveted longitudinal joints of a shell or drum which exceeds 36 in. in diameter, shall be of butt and double-strap construction. This rule does not apply to the portion of a boiler shell which is staybolted to the firebox sheet.

PAR. 190. CHANGE PAR. 190 TO READ AS FOLLOWS:

190 In horizontal return tubular boilers with lap joints no course shall be over 12 ft. long. With butt and double strap construction longitudinal joints of any length may be used provided the tension test specimens are so cut from the plate that their lengthwise direction is parallel with circumferential seams of the boiler and the tests meet the standards prescribed in the specifications for boiler plate steel.

PAR. 194. CHANGE THE FIRST SECTION OF PAR. 194 TO READ AS FOLLOWS:

194 *Domes.* The longitudinal joint of a dome 24 in. or over in diameter shall be of butt and double-strap construction irrespective of pressure. When the maximum allowable working pressure exceeds 100 lb. per sq. in. the flange of a dome 24 in. or over in diameter shall be double riveted to the boiler shell.

PAGE 49

PAR. 195. ADD AFTER NOTATION FOLLOWING FORMULA IN PAR. 195:

Where two radii are used the longer shall be taken as the value of L in the formula.

ADD AT THE END OF PAR. 195:

When a dished head has a manhole opening, the thickness as found by these Rules shall be increased by not less than $\frac{1}{8}$ in. over that called for by the formula.

PAGE 50

PAR. 199. ADD THE FOLLOWING TO THE LIST OF VALUES OF C IN PAR. 199:

$C = 150$ for stays screwed through plates or made a taper fit and having the heads formed on the stays before installing them and not riveted over, said heads being made to have a true bearing on the plate and the diameter of the heads being not less than 1.4 times the diameter of the stays.

REVISE MATTER FOLLOWING LIST OF VALUES OF C TO MAKE IT READ AS FOLLOWS:

If flat boiler plates not less than $\frac{3}{8}$ in. thick are strengthened with doubling plates securely riveted thereto and having a thickness of not less than 2/3 t, then the value of t in the formula shall be three-quarters of the combined thickness of the boiler plate and doubling plates but not more than one and one-half times the thickness of the boiler plate, and the values of C given above may also be increased 15 per cent.

When two sheets are connected by stays and but one of these sheets requires staying, the value of C is governed by the thickness of the sheet requiring staying.

PAR. 200. CHANGE PAR. 200 TO READ AS FOLLOWS:

200 *Staybolts.* The ends of screwed staybolts shall be riveted over or upset by equivalent process. Staybolts must be hollow or the outside ends of solid staybolts shall be drilled with a hole at least 3/16 in. diameter to a depth extending at least $\frac{1}{2}$ in. beyond the pressure side of the plates, except on boilers having a grate area not exceeding 15 sq. ft., or the equivalent in gas or oil fired boilers, where the drilling of the staybolts is optional. Flexible staybolts of either the jointed or ball and socket type need not be drilled.

PAR. 201. ADD TO PAR. 201 THE FOLLOWING:

If the outstanding legs of the two members are fastened together so that they may act as one member in resisting the bending action produced by the load on the rivets attaching the members to the head of the boiler, and provided that the spacing of these rivets attaching the members to the head is approximately uniform, the members may be figured as a single beam uniformly loaded and supported at the points where the through braces are attached.

PAGE 51

PAR. 203. CHANGE PAR. 203 TO READ AS FOLLOWS:

203*a* The maximum spacing between centers of rivets or between the edges of tube holes and the centers of rivets attaching the crowfeet of braces to the braced surface, shall be determined by the formula in Par. 199, using 135 for the value of C.

b The maximum distance between the edges of tube holes and the centers of other types of stays shall be determined by the formula in Par. 199 using the value of C given in Par. 199 which applies to the thickness of plate and type of stay used.

c The maximum spacing between the inner surface of the shell and lines parallel to the surface of the shell passing through the centers of the rivets attaching the crowfeet of braces to the head shall be determined by the formula in Par. 199, using 175 for the value of C.

d The maximum distance between the inner surface of the shell and the centers of braces of other types shall be determined by the formula in Par. 199 using a value of C equal to 1.3 times that value of C in Par. 199 which applies to the thickness of plate and type of stay as therein specified.

e In applying these rules and those in Par. 199 to a head or plate having a manhole or reinforced opening, the spacing applies only to the plate around the opening and not across the opening.

UNDER TABLE 3 INSERT:

For the application of Pars. 205, 206 and 207, see Appendix (Par. . . .) (illustrations in Case No. 13).

PAGE 53

PAR. 214. CHANGE PAR. 214 TO READ AS FOLLOWS:

214 *Areas of Segments of Heads to be Stayed.* The area of a segment of a head to be stayed shall be the area enclosed by lines drawn 2 in. from the tubes and a distance d from the shell as shown in Figs. 13 and 14. The value of d shall be the larger of the following values but not less than 3 in.

(Note:—Dimensions marked 3″ in Figs. 13 and 14 to be changed to d.)

(1) d = the outer radius of the flange not exceeding eight times the thickness of the head

(2) $d = \dfrac{5 \times t}{\sqrt{P}}$

Where

d = distance in inches
t = thickness of head in sixteenths of an inch
P = maximum allowable working pressure in lb. per sq. in.

PAR. 215. CHANGE PAR. 215 TO READ AS FOLLOWS:

215 When drum heads of water tube boilers are 30 in. or less in diameter and the tube plate is stiffened by flanged ribs or gussets, no stays need be used if a hydrostatic test to destruction of a boiler or unit section built

in accordance with the construction, shows that the factor of safety is at least 5.

PAR. 216. CHANGE PAR. 216 TO MAKE IT READ AS FOLLOWS:

216 Stays shall be used in the tube sheets of a fire tube boiler if the distance between the edges of the tube holes exceeds the maximum pitch of staybolts for the corresponding plate thickness and pressure given in Table 3. That part of the tube sheet which comes between the tubes and the shell need not be stayed if the nearest tangent common to two tube holes when measured on any radius of the tube sheet that intersects the tangent between the holes does not exceed this maximum pitch by more than 3 in. The tube holes to which a common tangent may be drawn in applying this rule shall not be at a greater distance from edge to edge than the maximum pitch referred to.

PAGE 54

PAR. 218. ADD THE FOLLOWING TO PAR. 218:

The distance in the clear between the bodies of the braces, or of the inside braces where more than two are used, shall not be less than 10 in. at any point.

PAR. 220. CHANGE PAR. 220 TO READ AS FOLLOWS:

220*a* The full pitch dimensions of the stays shall be employed in determining the area to be supported by a stay and the area occupied by the stay shall be deducted therefrom to obtain the net area. The product of the net area in square inches by the maximum allowable working pressure in lb. per sq. in. gives the load to be supported by the stay.

b Where stays come near bounding surfaces and special allowances are made for the spacing, the load to be carried by such stays shall be determined by neglecting the added area provided for by these special allowances. For example, if the minimum pitch by Table 3 would make a staybolt come 6 in. from the edge of the plate and a special allowance would make it come 7 in., the distance of 6 in. should be used in computing the load to be carried.

c The maximum allowable stress per square inch net cross sectional area of stays and staybolts shall be as given in Table 4.

d The length of the stay between supports shall be measured from the inner faces of the stayed plates. The stresses are based on tension only. For computing stresses in diagonal stays, see Pars. 221 and 222.

TABLE 4. ADD LINE AFTER ITEM *b* IN TABLE TO READ AS FOLLOWS:

c Steel through stays exceeding $1\frac{1}{2}$ in. diameter	10,400	9000

CHANGE PRESENT ITEM *c* IN TABLE TO ITEM *d*.

PAGE 55

PAR. 223. CHANGE PAR. 223 TO READ AS FOLLOWS:

223 ***Diameter of Pins and Area of Rivets in Braces.*** All rivet and pin holes shall conform with the requirements in Par. 253 and the pins shall be made a neat fit. To determine the sizes that shall be used proceed as follows:

1. Determine the "required cross-sectional area of the brace" by first computing the total load to be carried by the brace, and dividing the total load by the values of stresses for unwelded stays given in Table 4.

2. Design the body of the brace so that the cross-sectional area shall be at least equal to the "required cross-sectional area of the brace" for unwelded braces. Where the braces are welded, the cross-sectional area at the weld shall be at least as great as that computed for a stress of 6000 lb. per sq. in. (see Table 4).

3. Make the area of pins to resist double shear at least three-quarters of the "required cross-sectional area of the brace."

4. Make the combined cross-section of the eye at the side of the pin (in crowfoot braces) of at least 25 per cent greater than the "required cross-sectional area of the brace."

5. Make the combined cross-sectional area of the rivets at each end of the brace at least one and one-quarter times the "required cross-sectional area of the brace."

6. Design each branch of a crowfoot to carry two thirds the total load on the brace.

7. Make the net sectional areas through the sides of the crowfoot, tee irons, or similar fastenings at the rivet holes at least equal to the required rivet section, that is, at least equal to one and one-quarter times the "required cross-sectional area of the brace."

8. Make the cross-sectional areas through the blades of diagonal braces where attached to the shell of the boiler at least equal to the required rivet section, that is, at least equal to one and one-quarter times the "required cross-sectional area of the brace."

PAGE 58

PAR. 231. CHANGE PAR. 231 TO READ AS FOLLOWS:

231 *Maximum Allowable Working Pressure on Truncated Cones.* *a*. Upper combustion chambers of vertical submerged tubular boilers made in the shape of a frustum of a cone when not over 38 in. diameter at the large end, may be used without stays if figured by the rule for plain cylindrical furnaces (Par. 239) making D in the formula equal to the diameter at the large end.

b When over 38 in. in diameter at the large end, that portion which is over 30 in. in diameter shall be fully supported by staybolts or gussets to conform to the provisions for staying flat surfaces. In this case the top row of staybolts shall be at a point where the cone top is 30 in. or less in diameter.

In calculating the pressure permissible on the unstayed portion of the cone, the vertical distance between the horizontal planes passing through the centers of the rivets at the cone top, and through the center of the top row of staybolts shall be used as L in Par. 239, and D in that paragraph shall be the inside diameter at the center of the top row of staybolts.

PAGE 61

PAR. 239. CHANGE FIRST PARAGRAPH OF PAR. 239 TO READ AS FOLLOWS:

239 *Plain Circular Furnaces.* Unstayed furnaces *more than* 18 *in. diameter* when riveted or of seamless construction or such furnaces when lapwelded by the forging process shall have walls not less than 5/16 in. thick. The maximum allowable working pressure for such furnaces shall be determined by one or the other of the following formulæ:

MAKE DEFINITION OF L READ AS FOLLOWS:

L = total length of furnace between centers of head rivet seams (not length of a section), in.

INSERT AFTER THE FORMULA AND JUST PRECEDING THE EXAMPLE IN PAR. 239, ELIMINATING THE PRESENT SENTENCE:

Where the furnace has a riveted longitudinal joint, it may be of the lap type for inside diameters not exceeding 30 in. but shall be of butt and strap construction for inside diameters exceeding 30 in. The efficiency of the joint shall be greater than:—

$$\frac{P \times D}{1250 \times T}$$

PAGE 64

PAR. 246. CHANGE PAR. 246 TO PAR. 246*a*

PAR. 247. CHANGE PAR. 247 TO PAR. 246*b*

CHANGE PAR. 247 TO READ AS FOLLOWS:

247 Where it is impossible to calculate with a reasonable degree of safety the strength of a boiler structure or any part thereof, a full sized sample shall be built by the manufacturer and tested to destruction in the presence

of the Boiler Code Committee or a representative of the Boiler Code Committee appointed to witness such test.

Par. 250. Change Par. 250 to read as follows:

250 A fire-tube boiler shall have the ends of the tubes substantially rolled and beaded, or rolled and welded, at the firebox or combustion chamber end.

PAGE 65a

Par. 253. Change Par. 253 to read as follows:

253 *Riveting.* Rivet holes shall be drilled full size or they may be punched not to exceed 1/4 in. less than full diameter for material over 5/16 in. in thickness, and 1/8 in. less than full diameter for material not exceeding 5/16 in. in thickness, and then drilled or reamed to full diameter.

Par. 255. Add to Par. 255 the following:

Forms of rivet heads that will be acceptable are shown in Fig. 17*a*.

PAGE 65b

Par. 257. Change Par. 257 to read as follows:

257 *Calking.* The calking edges of plates, butt straps and heads shall be beveled. Every portion of the sheared surfaces of the calking edges of plates, butt straps and heads shall be planed, milled or chipped to a depth of not less than 1/8 in. Calking shall be done with a round-nosed tool.

PAGE 67

Par. 266. Change Par. 266 to read as follows:

266 A vertical fire-tube boiler, except boilers of steam fire-engines, or boilers 24 in. or less in diameter shall have not less than seven handholes, located as follows: Three in the shell at or about the line of the crown sheet; one in the shell at or about the water-line or opposite the fusible plug when used; three in the shell at the lower part of the waterleg. A vertical firetube boiler, submerged tube type, shall have two or more handholes in the shell, in line with the upper tube sheet. All boilers 24 in. or less in diameter, shall have at least one opening for inspection and one opening in addition to the blow-off, for washing out the boiler, these openings to be fitted with brass plugs.

PAGE 68

Par. 268. Change Par. 268 to read as follows:

268 *Threaded Openings.* An opening in a boiler for a threaded pipe connection 1 in. in diameter or over shall have not less than the number of threads given in Table 7.

INSERT TABLE HERE

If the thickness of the material in the boiler is not sufficient to give such number of threads, there shall be a pressed steel flange, bronze composition flange, steel-cast flange or steel plate, so as to give the required number of threads.

Par. 269. Change Par. 269 to read as follows:

269 *Safety Valve Requirements.* Each boiler shall have two or more safety valves, except a boiler for which one safety valve 2 in. size or smaller is required by these Rules; in which case one or more may be used.

PAGE 69

Par. 273. Change Par. 273 to read as follows:

273 Each safety valve shall be plainly marked by the manufacturer. The markings may be stamped on the body, cast on the body or stamped or cast on a plate or plates riveted to the body and shall contain the following:

a. The name or identifying trademark of the manufacturer

b. The nominal diameter with the words "Bevel Seat" or "Flat Seat"

c. The steam pressure at which it is set to blow

d. The lift in inches of the valve disc from its seat, measured at a pressure 3 per cent higher than that at which the valve is set to blow

e. The weight of steam discharged in pounds per hour at a pressure 3 per cent higher than that for which valve is set to blow

PAGES 70-71-72

Table 8. Table 8 to be omitted.

PAGE 73

Par. 275*a*. Change Par. 275*a* to read as follows:

275 Safety valve capacity may be checked in any one of three different ways, and if found sufficient, additional capacity need not be provided:

a. By making an accumulation test, that is, by shutting off all other steam discharge outlets from the boiler and forcing the fires to the maximum. The safety valve equipment shall be sufficient to prevent an excess pressure beyond that specified in Par. 270.

Par. 279. Add to Par. 279 the following:

279 Where discharge pipes are used ample drainage shall be provided at or near the safety valve.

PAGE 74

Par. 282. Change Par. 282 to read as follows:

282 For purposes of inspection and to insure the valve being free, each safety valve used on a boiler shall have a substantial lifting device by which the valves may be raised by an amount equal to one-twentieth of the nominal diameter of the valve up to the maximum limit of 1/16 in. when there is no pressure on the boiler.

Par. 283. Add to Par. 283 the following:

The seats and discs of safety valves shall be non-ferrous material. The seat of a safety valve shall be fastened to the body of the valve in such a way that there is no possibility for the seat to lift.

Add to Par. 284 the following:

Springs used in safety valves shall not show a permanent set exceeding 1/32 in. ten minutes after being released from a cold compression test closing the spring solid. And the spring shall be so constructed that the valve can lift from its seat one-tenth the diameter of the seat before the coils are closed or before there is other interference.

Par. 286. Change Par. 286 to read as follows:

286 All dimensions shall conform to the American Standard given in Tables 15 and 16 of the Appendix for the pressure therein specified, except that the face of the safety valve flange and the nozzle to which it is attached shall be flat and without the raised face for pressures up to and including 250 lb. per sq. in. For higher pressure, the raised face shall be used.

PAGE 75

Par. 291. Add to Par. 291 the following:

The lowest permissible water level for various classes of boilers is given in Par. 430 of the Appendix.

Par. 292. Change Par. 292 to read as follows:

292 No water glass connection shall be fitted with an automatic shut-off valve, except when the automatic shut-off valves are so constructed that the two connections to the water glass can be blown through separately and the steam connection cannot be entirely closed thereby.

Par. 296. Add to Par. 296 the following:

Where the use of a long pipe becomes necessary a shut-off valve or cock arranged so that it can be locked or

sealed open may be used near the boiler. Such a pipe shall be of ample size and arranged so that it may be cleared by blowing out.

PAGE 76

Par. 299. Change Par. 299 to read as follows:

299 *Nozzles and Fittings.* Flanged cast iron pipe fittings used for boiler parts, for pressures up to and including 160 lb. per sq. in. shall conform to the American Standard given in Tables 15 and 16 of the Appendix, except that the face of the flange of a safety valve as well as that of a safety valve nozzle, shall be flat and without the raised face. For pressures above 160 lb. per sq. in., steel cast and wrought steel fittings shall be used for boiler parts with exceptions specified in Pars. 9 and 12. An allowable variation of 20 per cent from the flange thickness required by Tables 15 and 16 may be made for steel cast and forged steel fittings, leaving the drilling of bolt holes unchanged. For pressures above 250 lb. per sq. in., the flange thickness and the thickness of the bodies shall be increased to keep within the same deflection limits and to give at least the same factor of safety as the fittings specified in Tables 15 and 16. The face of the flange of a safety valve, as well as that of a safety valve nozzle, shall have a flat face for pressures up to and including 250 lb. per sq. in. and shall have raised face at higher pressures. Tables 15 and 16 do not apply to flanges on the boiler side of steam nozzles or to flanges left by the manufacturer as part of the boiler, and do not apply to fittings designed as part of the boiler.

Par. 307. Change Par. 307 to read as follows:

307 *Blow-Off Piping.* A surface blow-off pipe shall not exceed $1\frac{1}{2}$ in. pipe size and shall form a continuous passage with the blow-off pipe external to the boiler. The internal and external pipes shall be separate with clearance between their ends and arranged so that the removal of either will not disturb the other. A brass or steel bushing as shown in Fig. 19, or flanged connection shall be used.

PAGE 77

Par. 311. Change Par. 311 to read as follows:

311*a*. When the maximum allowable working pressure exceeds 125 lb. per sq. in., on all boilers except those used for traction and portable purposes, each bottom blow-off pipe shall have two valves, or a valve and a cock, and such valves, or valve and cock, shall be extra heavy, except that on a boiler having multiple blow-off pipes, a single master valve may be placed on the common blow-off pipe from the boiler, in which case only one valve on each individual blow-off is required.

b. On all traction and portable boilers when the maximum allowable working pressure exceeds 125 lb. per sq. in., each bottom blow-off pipe shall have one extra heavy valve.

Par. 315. Make the last sentence of Par. 315 read as follows:

The feed pipe shall be carried through the head or shell near the front end in the way specified for a surface blow-off in Par. 307 and be securely fastened inside the shell above the tubes.

PAGE 79

Par. 325. Change Par. 325 to read as follows:

325 Lugs or brackets, when used to support boilers of all types shall be properly fitted to the surfaces to which they are attached. The shearing and crushing stresses on the rivets used for attaching the lugs or brackets shall not exceed 8 per cent of the strength given in Pars. 15 and 16.

Par. 328. Change Par. 328 to read as follows:

328 A water tube boiler which is fired by hand shall have the firing door or doors of the inward opening type unless such doors are provided with substantial and effective latching devices to prevent them from being blown open by pressure on the furnace side.

PAGE 80

Fig. 20. Change Fig. 20, Par. 332, to read as follows:

(Name of State)
..................STD
Year put into service.
Safe Working Pressure.
(Name of Builder)
....

PAGE 81

Par. 339. Change Par. 339 to read as follows:

339 A boiler to be used exclusively for low pressure steam heating may be constructed either of cast iron, steel cast, or wrought iron or steel or any combination of these, but in all cases the connecting rods and bolts shall be wrought iron or steel.

PAGE 82

Par. 343. Change Par. 343 to read as follows:

343 In a *hot-water* boiler to be used exclusively for heating buildings or hot water supply, when the diameter does not exceed 60 in. and the grate area does not exceed 10 sq. ft., or equivalent, as defined in Pars. 359 and 360, longitudinal lap joints will be allowed.

When the grate area exceeds 10 sq. ft., or equivalent, as defined in Par. 360, and the diameter of the boiler does not exceed 60 in. longitudinal lap joints will be allowed, providing the maximum allowable working pressure does not exceed 50 lb. per sq. in.

PAGE 84

Table 9. Title of Table 9 to be changed to read as follows:

Allowable Sizes of Safety Valves for Steam Heating Boilers, of Water Relief Valves for Water Heating Boilers, and of Hot Water Supply Boilers.

PAGE 85

Pars. 359 and 360. Insert the following center head:

GRATE AREA

Par. 359. Change Par. 359 to read as follows:

359 *Double Grate Down Draft Boilers.* In boilers of this type the grate area shall be taken as one and one-quarter times the area of the lower grate.

Par. 361. Change Par. 361 to read as follows:

361 *Steam Gages.* Each *steam* boiler shall have a steam gage connected to the steam space or to the water column or its steam connection, by means of a syphon or equivalent device of sufficient capacity to keep the gage tube filled with water and so arranged that the gage cannot be shut off from the boiler except by a cock placed near the gage and provided with a tee or lever handle arranged to be parallel with the pipe in which it is located when the cock is open. Connections to gages shall be of brass, copper or bronze composition. The dial of a steam gage for a *steam* heating boiler shall be graduated to not less than 30 lb.

PAGE 86

Par. 365. Change Par. 365 to read as follows:

365 *Damper Regulators.* When a pressure damper regulator is used, it shall be connected to the steam space of the boiler.

PAGE [illegible]

PAR. [illegible]. CHANGE PAR. [illegible] TO READ AS FOLLOWS:

[illegible] *Hot water boilers* for a maximum allowable working pressure not exceeding 30 lb. per sq. in. used exclusively for heating buildings or for hot water supply, when constructed of cast iron, steel cast, or wrought iron or plate steel or any combination of these, shall be subjected to a shop test of 60 lb. per sq. in. hydrostatic pressure applied to the boiler or the section thereof.

PAR. 371. CHANGE PAR. 371 TO READ AS FOLLOWS:

371 A maximum allowable working pressure in excess of 30 lb. per sq. in. will be allowed on a hot water boiler constructed of cast iron, steel cast, or wrought iron or plate steel or any combination of these, used exclusively for heating buildings or for hot-water supply, provided such boilers or their sections have been subjected to a shop hydrostatic test of two and one-half times the actual working pressure.

PAR. 377. CHANGE PAR. 377 TO READ AS FOLLOWS:

377 *Name.* All boilers referred to in this section shall be plainly and permanently marked with the manufacturer's name and the maximum allowable working pressure.

All heating boilers built according to these rules may be marked A.S.M.E. standard.

PAGE 91

PAR. 391*a*. CHANGE PAR. 391*a* TO READ AS FOLLOWS:

391 Safety valve capacity may be checked in any one of three different ways, and if found sufficient, additional capacity need not be provided:

a By making an accumulation test, that is, by shutting off all other steam discharge outlets from the boiler and forcing the fires to the maximum. The safety valve equipment shall be sufficient to prevent an excess pressure beyond that specified in Par. 270.

PAGE 93

PAR. 402. CHANGE PAR. 402 TO READ AS FOLLOWS:

402 When the maximum allowable working pressure exceeds 125 lb. per sq. in., the blow-off pipe shall be extra heavy from boiler to valve or valves, and shall run full size without reducers or bushings. All fittings between the boiler and valve shall be steel or extra heavy fittings of bronze, brass, malleable iron or cast-iron.

PAGE 107

PAR. 421. CHANGE PAR. 421 TO READ AS FOLLOWS:

421 *Method of Computing Discharge Capacity.* The required discharge capacity of a safety valve or valves for a boiler may be based either on the heat units in the fuel consumed or on the amount of steam generated.

The number of heat units that each safety valve will handle, for valves of the ordinary types in which the discharge capacity is proportioned to the lift, may be obtained as follows:

$U = 161{,}000 \times P \times D \times L$ for Bevel Seats at 45 deg.
$U = 227{,}500 \times P \times D \times L$ for Flat Seats

The amount of steam that a valve will discharge may be found as follows:

$W = 110 \times P \times D \times L$ for Bevel Seats at 45 deg.
$W = 155 \times P \times D \times L$ for Flat Seats

Where

U = Number of heat units per hour that a safety valve will handle, B.t.u.
W = Quantity of steam that a safety valve will handle per hour, lb.
P = Absolute boiler pressure or gage pressure plus 14.7 lb. per sq. in.
D = Inside diameter of valve seat, in.
L = Vertical lift of valve disc, measured with 3 per cent excess pressure, in.

PAR. 422. CHANGE PAR. 422 TO READ AS FOLLOWS:

422 The maximum quantity of fuel C that can be burned per hour at the time of maximum forcing is determined by a test. The maximum number of heat units per hour, or $C \times H$ is then determined, using the values of H given in Par. 427. The weight of steam generated per hour is found by the formula:

$$W = \frac{C \times H \times 0.75}{1{,}100}$$

The sum of the safety valve capacities marked on the valves shall be equal to or greater than W.

PAGE 108

PAR. 423. REPLACE MATTER AFTER STATEMENT OF EXAMPLE BY:

$$C \times H = 2150 \times 12{,}100 = 26{,}015{,}000$$
$$W = C \times H \times 0.75 \div 1100 = 17{,}740$$

A $3\frac{1}{2}$ in. bevel seated valve with 0.11 in. lift would discharge in heat units

$$U = 161{,}000 \times 239.7 \times 3\tfrac{1}{2} \times 0.11 = 14{,}858{,}000$$

and in weight of steam

$$W = 110 \times 239.7 \times 3\tfrac{1}{2} \times 0.11 = 10{,}150$$

From which it can be seen that either method indicates that two such valves will give the proper relieving capacity.

PAR. 424. REPLACE MATTER AFTER STATEMENT OF EXAMPLE BY:

$$C \times H = 2000 \times 6400 = 12{,}800{,}000$$
$$W = C \times H \times 0.75 \div 1100 = 8730$$

A bevel seated $3\frac{1}{2}$ in. valve is marked by the manufacturer 0.11 in. lift and discharge capacity for 100 lb. pressure = 4840 lb.; hence two such valves would be required.

PAR. 425. REPLACE MATTER AFTER STATEMENT OF EXAMPLE BY:

$$C \times H = 1000 \times 18{,}500 = 18{,}500{,}000$$
$$W = C \times H \times 0.75 \div 1100 = 12{,}620$$

A bevel seated $2\frac{1}{2}$ in. valve is marked by the manufacturer 0.08 in. lift and discharge capacity for 275 lb. pressure = 6350 lb.; hence two such valves would be required.

PAR. 426. REPLACE MATTER AFTER STATEMENT OF EXAMPLE BY:

$$C \times H = 3000 \times 960 = 2{,}880{,}000$$
$$W = C \times H \times 0.75 \div 1100 = 1960$$

A bevel seated 2 in. valve is marked by the manufacturer 0.07 in. lift and discharge capacity for 150 lb. pressure = 2500 lb.; hence one such valve would be required.

PAGE 109

PAR. 427. CHANGE PAR. 427 TO MAKE FIRST SENTENCE READ AS FOLLOWS:

For the purpose of checking the safety valve capacity as described in Par. 422, the following values of heats of combustion of various fuels may be used.

ALSO CHANGE HEADINGS IN TABLES WHICH FOLLOW TO MAKE THEM READ:

H = B.t.u. per lb.

and

H = B.t.u. per cu. ft.

PAGES 113-114

PAR. 430. MAKE FIRST LINE OF PAR. 430 TO READ AS FOLLOWS:

430 Each boiler may have one or more fusible plugs located at the lowest permissible water level as follows:

ADD AT THE BOTTOM OF P. 114 (PAR. 430):

r Fire Engine Boilers are not usually supplied with fusible plugs. Unless special provision is made to keep the water above the firebox crown sheet other than by the natural water level, the lowest permissible water level shall be at least 3 in. above the top of the firebox crown sheet.

Society Affairs

Engineering Survey

Prizes for Technical Papers

JUNE 30 is the last day for submitting papers for consideration by the Committee on Award of Junior Prizes for the Cash Prize of $50 and Engraved Certificate, available for the best paper of the year by a Junior Member, and for consideration by the Committee on Award of Student Prizes for the two Cash Prizes of $25 each and Engraved Certificates, available for the two best papers of the year by enrolled members of Student Branches of the Society.

The prizes will be awarded for the papers adjudged best from the standpoints of originality of matter, applicability (practical or theoretical), value as a contribution to technical literature, logical development of contents, conclusiveness, completeness, conciseness, or such standpoints as the Committees may determine.

Papers must be the bona fide production of their authors. In the case of papers by Junior Members, they must not have been previously contributed to, nor published by, any other society in whole or in part. Papers by members of Student Branches, however, may have been presented before a regular meeting of a branch.

Manuscripts should be preferably typewritten in doublespacing, on sheets of uniform size, say, 8½ x 11 in., with illustrations neatly drawn and tabular matter clearly arranged.

Full information regarding these prizes and the rules of their award is published on pp. XXVI and XXVII of the 1917 Year Book, and the Rules of Award are given on pp. 508 and 509 of the same volume.

Membership in the Am. Soc. M. E.

C 9 A Member shall be an Engineer or Teacher of Applied Science of thirty-two years of age, or over, and shall have been in the active practice of his profession for at least ten years and in responsible charge of important work for five years, and shall be qualified to design as well as to direct engineering work. Fulfilling the duties of a professor of engineering who is in charge of a department in a college or school of accepted standing shall be taken as an equivalent to an equal number of years of active practice. Graduation from a school of engineering of recognized standing shall be considered as equivalent to two years of active practice.

C 10 An Associate shall be thirty years of age or over. He need not be an Engineer, but must have been so connected with some branch of Engineering or science, or the arts, or industries, that the Council will consider him qualified to coöperate with Engineers in the advancement of professional knowledge.

C 11 An Associate-Member shall be a professional engineer not less than twenty-seven years of age, who shall have been in the active practice of his profession for at least six years, and who shall have had responsible charge of work as principal or assistant for at least one year. Graduation from a school of engineering of recognized reputation shall be considered as equivalent to two years' active practice.

C 12 A Junior shall be twenty-one years of age or over. He must have had such engineering experience as will enable him to fill a subordinate position in engineering work, or he must be a graduate of an engineering school.

SOCIETY AFFAIRS

A Record of the Current Activities of the Society, Its Members, Council, Committees, Sections and Student Branches; and an Account of Professional Affairs of Interest to the Membership

THE SPRING MEETING AT CINCINNATI

THE largest audience at any Spring Meeting of the Society was present at the joint meeting with the Machine Tool Builders' Association on Tuesday afternoon, May 22. The meeting was addressed by Dean Herman Schneider, of the University of Cincinnati, on The Trend in Engineering Training, and by Dr. Otto P. Geier, social physician of the Cincinnati Milling Machine Company, on The Human Potential in Industry.

Dean Schneider outlined various educational plans for bringing the student in contact with practical work in the industries and with the workmen. He illustrated with lantern slides the work of his own students of the University of Cincinnati, under the well-known coöperative plan which he has so successfully carried out with Cincinnati firms for regular employment in the shops during the college course.

Dr. Geier's address was an inspiration in showing the important service which the social physician can render in maintaining the health of the workers and removing physical causes leading to lack of interest or loss of time; and by developing intimate relations in a way to be genuinely helpful to the employees.

The two addresses were delivered to indicate the attention which industrial Cincinnati is giving to the human side of industrial problems. The visitors were urged to remain longer in the city in order to study these methods at first hand.

The meeting concluded with some excellent and unusual moving pictures of the manufacture of 9.2 shells, arranged for and contributed by the publishers of *Machinery*.

Notes

Council Meeting. The Council directed the issuing of a questionnaire to the membership, to provide for the enlisting of members in the public service in the present emergency, and also for the future needs of the Society.

Business Meeting. Amendments to the Constitution proposed by the Constitution and By-Laws Committee were announced. It was stated by the President that the Council, as expressing the obvious desire of the whole membership, had voted to invest in Liberty Bonds part of the money necessarily needed in the running of the Society, even at some possible inconvenience.

General Session. President Hollis, Vice-President Benjamin and Manager Toltz presided alternately. At the close, Mr. Toltz spoke of his recent trip to Honolulu and his reception by the A.S.M.E. members there and the Hawaiian Engineering Association. He brought the greetings of the latter to the Society. Attendance about 220.

Registration. Indications are, at time of going to press, that the registration will exceed that at any previous Spring convention. The total number of members registered at end of the second day was 370, and the total of guests 490. Attendance at previous largest Spring Meetings: Chicago (1904), 350; Pittsburgh (1911), 305.

At the Machine Shop Session there were 200 in attendance throughout, many standing in the room.

An enthusiastic conference of delegates from local Sections was held, at which each man from each city recited briefly the experiences of his organization for the year and outlined plans of future work. Sections Committee Chairman Yarnall described plans of the Sections Committee to make the Sections the strongest factor in the Society work. Both President Hollis and Secretary Rice told the delegates frankly that their first aim should be service to their communities. The delegates accorded a rising vote of thanks of the Sections to the Cincinnati Local Committee for the splendid arrangements for the Spring Meeting.

The University of Cincinnati Student Branch held an enthusiastic meeting at the University on Tuesday evening. About 75 were present. Secretary Rice opened the meeting. President Hollis, Mr. William Kent, Mr. Carl G. Barth, and Mr. L. P. Alford gave good talks to the men. These were followed by an entertainment and smoker, arranged for and carried out by the students.

THE SECRETARY'S MONTHLY LETTER

THE coöperation of the Society with the Government, as was outlined in last month's Journal, is developing still more intimately. Calls from the departments directly and by firms responding to Government emergency orders are frequent.

As an outgrowth of the activity of members of our Society in their relation as citizens of Fairfield County, Connecticut, in the Fairfield County Resource Mobilization Committee, a meeting of The American Society of Mechanical Engineers from not only Bridgeport but all of the surrounding towns was held this month, attended by the members of the Sections Committee with the result, as elsewhere reported in this issue, that an Organization Committee has been appointed with representatives from each of the big centers in Connecticut, to draw up a plan whereby the whole State of Connecticut will be provided with section meetings. With this as a precedent, it is hoped to extend the Society organization through many other similarly thickly populated districts so that the benefits of membership will be still further extended.

As is stated in another place, and of such importance that it should be repeated here, the National Academy of Sciences has just elected four engineers, which, so far as I am informed, is the first time that an engineer as such has been elected to the highest body of men of science of any country.

Science are physicists and chemists, the reason always being here because of the sharp distinction drawn between pure and applied science. The two members of our Society who were elected are Prof. W. F. Durand and Dr. S. W. Stratton, the member of the Mining Engineers was Dr. Henry M. Howe, and of the Electrical Engineers, Mr. J. J. Carty. It has been indicated previously and particularly in the last number of THE JOURNAL that the engineering societies are closely coöperating through the Engineering Foundation with the National Research Council appointed by the President of the National Academy of Sciences. This coöperation is destined to be very close, and in fact the resources of the entire Society will sooner or later be called on by the Research Council.

The sole ambition of the Society is to render the greatest possible service to the Government, under all circumstances.

As an outcome of the extraordinary activity of the Government in munition manufacture, several pieces of standardization work, which are now especially urgent, will undoubtedly be started or revived, and the coöperation of the members of the Society is specially urged for the sake of the country. Obviously, inconvenience and perhaps some actual loss of stocks will follow the processes of standardization, but with the proper attitude on the part of all, these losses can be minimized and the greatest good secured.

The Secretary also wishes to ask the assistance and the coöperation of the membership in the Industrial Census supplementing that taken last year but undertaken now under the auspices of the states. The members are requested to kindly notify the Secretary of all such requests so that the machinery of the Society can always be availed of to the fullest extent.

CALVIN W. RICE,
Secretary.

Council Notes[1]

THE following members were present at the meeting of the Council on April 20: Ira N. Hollis, *President,* John H. Barr, C. E. Benjamin, R. H. Fernald, W. F. M. Goss, A. M. Greene, Jr., F. R. Hutton, W. B. Jackson, D. S. Jacobus, C. T. Main, C. T. Plunkett, John A. Stevens, and Calvin W. Rice, *Secretary.* Louis C. Marburg, member of the Sections Committee, and F. R. Low, chairman of the Publication Committee, were also present by invitation.

In view of the present national emergency, it was voted that authority be given to the President to nominate, subject to confirmation of the Council, such additional committees and representatives as may be requested from time to time by either the Council of National Defense or the National Research Council.

Council of National Defense. In response to an invitation from the Advisory Commission of the Council of National Defense, it was voted that the President and Secretary be nominated to represent this Society on the Commission's Committee on Science and Research, including Engineering and Education.

Engineering Committee of National Research Council. In response to the invitation of the National Research Council, W. F. Durand and Charles D. Young were nominated to represent this Society on the Engineering Committee of the Council. The Secretary announced that John R. Freeman had been elected a member-at-large on the National Research Council.

Advisory Committee on Gunmounts. The Council acknowledged and accepted as a command from the Secretary of War, the appointment of President Hollis and Past-President Jacobus to act on a special advisory committee on gunmounts.

Conserving Engineering Resources. Dr. Jacobus spoke of the desirability of placing on record an opinion that for the best interests of the country effort should be made to conserve the engineering talent as represented in the colleges of the country, both in graduate and undergraduate bodies, and to prevent if possible too hasty enlistment in the regular army and naval militia service. It was voted that Dr. Hollis Godfrey be invited to address a letter to the various colleges, informing them of the best use to which students and graduates can be put at this time, and advising that these men be conserved for the special fields in which their training would be especially useful and adaptable.

Engineer Officers' Reserve Corps. The name of the Joint Committee on Engineer Officers' Reserve Corps was changed to Committee on National Defense, the committee to coöperate with similar committees of the other societies. The committee has recently addressed instructions to the members of the Society who contemplate enlistment in the Army or Navy.

Military Engineering Committee. In response to the request of the chairman, and uniform with the action of the other three national engineering societies, the members of this Society now serving on the Military Engineering Committee of New York were authorized and appointed to represent the Society. These members are: Messrs. Gano Dunn, Alexander C. Humphreys, D. S. Jacobus, John W. Lieb, Ralph D. Mershon, Calvin W. Rice, W. L. Saunders, Bradley Stoughton, and W. H. Wiley.

National Academy of Sciences. The Secretary announced that Prof. W. F. Durand had been elected a member of the Academy.

U. S. Bureau of Mines. In response to a request from the Bureau of Mines for the appointment of a special Advisory Committee to the Bureau, and two sub-committees on Fuel and Mine Equipment, the Research Committee was appointed as the Special Advisory Committee.

Engineering Council. Amendments to the By-Laws of The United Engineering Society, creating The Engineering Council, "to consider means for more intimate relations between engineers for discussion of questions of general interest and for united action," were approved.

Constitution and By-Laws. Important changes in the Constitution and By-Laws of the Society were proposed by the Committee on Constitution and By-Laws and will be presented at the Council meeting to be held at Cincinnati on May 21, in connection with the Spring Meeting.

Membership Committee. The Secretary reported difficulty and embarrassment on the part of the Membership Committee to meet regularly, on account of the extraordinary pressure of personal business and national affairs, and it was voted that a statement be made in THE JOURNAL that on account of present conditions the matter of election to membership must necessarily proceed more slowly than usual.

A.S.M.E. Boiler Code. Interpretations in cases Nos. 136 to 145 were approved and ordered published in THE JOURNAL. They were included in the May issue.

Sections. The formation of a Section in Toronto, Canada, to include all members residing within a radius of sixty miles but not outside the Province of Ontario, and in the following cities in Ontario: Ashburnham, Collingwood, Cobourg, Oril-

[1] The May JOURNAL went to press before the April meeting.

ha, Palmerston, Port Dover, Peterborough, and Waterford, was approved.

Oscar Elsas, chairman, Cecil P. Poole, secretary, Earl F. Scott, Robert Gregg, and J. N. G. Nesbit were approved as the Executive Committee of the Atlanta Section, to continue in office until July 1, 1918.

P. N. Engel was appointed secretary of the Chicago Section, to succeed R. F. Thayer.

George I. Rockwood, chairman, R. G. Williams, secretary, V. P. Edwards, H. P. Fairfield, and F. W. Parks were appointed as the Executive Committee of the Worcester Section, to take office July 1, 1917.

Spring Meeting, 1918. It was voted to accept the invitation of the City of Worcester, Mass., to hold the Spring Meeting, 1918, in that city.

Graphics Committee. H. E. Crampton, representing the American Genetic Association, and Henry H. Norris, representing the Society for the Promotion of Engineering Education, were appointed as members of the Joint Committee on Standards for Graphic Presentation.

Calvin W. Rice,
Secretary.

Past-Presidents in Hawaii

We have now received an account of the visit of Past-Presidents Brashear, Swasey, and Freeman to Hawaii, in connection with their tour of the Orient. The party was entertained by the Hawaiian Engineering Association at a number of affairs. They were met by a committee from the association, consisting of Messrs. W. G. Hall, Mem.Am.Soc.M.E., Carl B. Andrews, R. R. Hind, Mem.Am.Soc.M.E., S. T. Carr, B. F. Howland, J. M. Young, Mem.Am.Soc.M.E., and E. Köpke, Mem.Am.Soc.M.E.

Their stay at the Island is best described in the following letter from Mr. Swasey, just received:

My Dear Mr. Rice:

Our excursion to the Hawaiian Islands was especially interesting, made doubly so by Messrs. B. F. Howland and E. Köpke, who were delegated by the Hawaiian Engineering Society to accompany us.

We first stopped at the Island of Maui, and there visited the Crater of Haleakala (House of the Sun), the largest extinct volcano in the world. The crater is about 7½ miles long; 2½ miles wide, and ½ mile deep. We went by automobile to the Half-way House, about 5,000 ft. in elevation, and Mr. Brashear remained there all night. The rest of us took ponies and went on to the summit. We were fortunate in having a beautiful view, and we remained over night, returning to the Half-way House about noon the next day, and then on down to the sea level.

We also visited one of the most up-to-date sugar refineries on the island, and were given every opportunity to see the most advanced methods and processes for extracting sugar from the cane.

That night we went by boat to Hilo, on the Island of Hawaii, where a special train was awaiting us for a trip along the coast, through interesting sugar plantations, a distance of about 35 miles. Returning to Hilo, we took autos and went to the volcano of Kilauea, about 30 miles distant, and about 4,000 ft. high, which is one of the most wonderful sights of the world. The crater is about 1,200 ft. in diameter, and the lake of fire is about 125 ft. from the top. When I was there about six years ago, it was about 450 ft. from the top. We remained at the Volcano House over night, and thus had a chance to see the crater by night. It is even more wonderful then than by day.

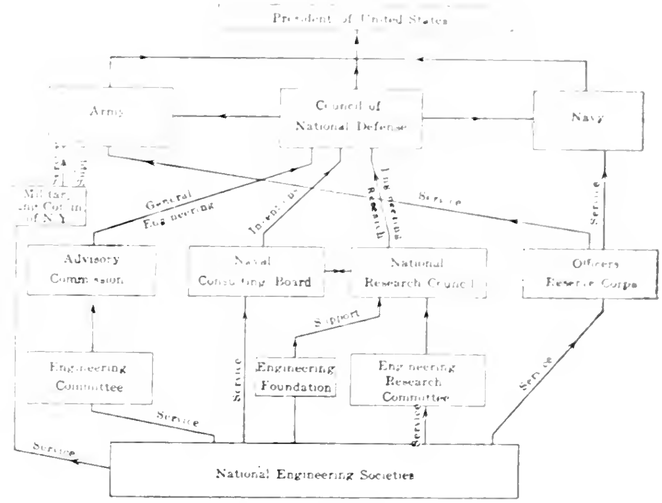
The next morning we returned to Hilo, and then took the boat for Honolulu, arriving there Saturday morning. The whole trip, extending from Monday afternoon until Saturday morning, was extremely interesting, and gave us an opportunity to see something of the wonderful productive possibilities of these rich islands. The ten days we spent in Honolulu and in visiting the various islands were among the most pleasant of our entire trip and I shall ever have happy memories of the good friends who did so much for us while we were there.

Very truly yours,
(Signed) Ambrose Swasey

To add to the distinction of having our three past-presidents at the islands, Mr. Max Toltz, member of the Council of the Society, was also at Honolulu, and he too was the guest of the local engineering association.

Engineers and the Government

Last month we published an account of the agencies through which the membership of the national engineering societies is in contact with the Government in the present emergency. We reproduce herewith a chart which visualizes the relationship of these agencies.



Connections Between the Government and the Engineers

The Military Engineering Committee of New York, shown on the left of the diagram as connecting the societies directly with the Army, is the outcome of the military engineering lectures organized in New York City some twelve months ago in the interest of Preparedness. The committee is organizing a regiment of engineers in the metropolis to be sent to France as soon as equipped.

The members of our Society on this committee are Messrs. Gano Dunn, Alex C. Humphreys, D. S. Jacobus, John W. Lieb, Ralph D. Mershon, Calvin W. Rice, W. L. Saunders, Bradley Stoughton, and W. H. Wiley.

There has also just been organized by President Hollis a Committee of our Society on Military Personnel. This committee will procure and classify information regarding the qualifications of the members, particularly with reference to their ability to serve the country.

Engineers Elected to Academy

The National Academy of Sciences has conferred a distinct honor upon the engineering profession by electing to its membership four engineers: Prof. W. F. Durand, Mem.Am.Soc.M.E., Dr. S. W. Stratton, Mem.Soc.M.E., Dr. Henry M. Howe and Mr. J. J. Carty. The Academy has also conferred upon Dr. Stratton the Public Welfare Medal.

The Academy is not so well known, perhaps, among engineers, but the significance of these elections may be judged from the facts that new members are chosen from the most distinguished men of the United States, and that the Academy is analogous to the Royal Society of London.

The Academy was incorporated in 1863 for the purpose of examining and investigating any subject of science or art and for making reports of special investigations at the call of the United States Government. It has about 150 members and 45 foreign associates, and a number of standing committees, including mathematics, physics and engineering, and weights, measures and coinage.

A new president of the academy has just been elected, Dr. Charles D. Walcott, secretary of the Smithsonian Institution, who succeeds Prof. William H. Welch. Dr. A. A. Michelson has been elected to the vice-presidency to fill the vacancy caused by this election.

The Academy is now in contact with the Government through the National Research Council which was recently appointed at the request of President Wilson. An account of the formation and work of the council was given in the last issue of THE JOURNAL.

Presentation of the John Fritz Medal

The John Fritz Medal, awarded to Dr. Henry Marion Howe, in January of this year, for "his investigations in metallurgy, especially in the metallography of iron and steel," was presented to him in the Auditorium of the Engineering Societies Building, New York, on the evening of Thursday, May 10. A full account of the ceremonies will appear in the July issue of THE JOURNAL.

Patriotic Dinner at Providence

The second annual dinner of the Providence Engineering Society, affiliated with the Am.Soc.M.E., held on the evening of May 2, was characterized as an expression of "rampant patriotism." At the head tables were representatives of Belgium, Canada, France and the United States. Each speaker received his full meed of praise, but it fell to the lot of Capt. M. de Jarny, a French military officer sent to this country after 18 months' service in the trenches to instruct the Harvard training camp, to receive round after round of applause. A few minutes later, Capt. Nathan Horowitz, representing the United States Army, received almost as enthusiastic a reception. Prof. Albert Van Hecke, of the University of Louvain, spoke for Belgium and showed motion pictures of efficiency methods adopted in the refugee camps in Holland, and which had been worked out by himself.

On the stage, behind the speakers' table, was a representation of a bivouac, with stacked rifles, shelter tents, packs and other military equipment. Also in evidence was a new projection machine, given to the society by John R. Freeman, Mem.Am.Soc.M.E.

Mayor Gainer was the first speaker, after R. W. Adams, the vice-president of the society, had presented Col. H. Anthony Dyer as toastmaster. The Mayor welcomed the distinguished guests of the evening.

Captain de Jarny followed, saying in part:

"The United States, the greatest engineering country in the world, is sure to play a great part in the war because it is an engineers' war. Here in Rhode Island, engineering has been developed to a greater extent than in any other part of the country, for it is here that are built those delicate machines, without which we would not have been able to continue the war.

"One of your most important duties is to supply all the Allies with materials, and I feel sure that your work will be well done."

Captain Horowitz declared that the word "engineer" is a synonym for efficiency, and that efficiency must guide every action taken by the citizens of this country, so that all our resources may be used to the best advantage.

President Hollis was also among the speakers and said on behalf of the United States:

"Many of the young men have asked me during the last few weeks how they could do their share. Our country must provide a man for every place, and we must have an agency of the Government to allot the men to the places where they can best serve. We serve best, in this funeral procession on the way to the burial of the divine right of kings, when we fit into the place where we can do the most good."

Professor Van Hecke closed the evening with a vivid portrayal of the part Belgium has played in the war.

Spring Meeting of Boston Section

THE Spring Meeting of the Boston Section of the American Society of Mechanical Engineers was held on Thursday afternoon and evening, May 17, 1917.

It was originally planned to make this a machine-tool meeting, but the crisis in the life of the country made it appear that a staid, theoretical discussion would be rather out of place at the present hour. The program was therefore devoted to one of the most vital subjects in the scheme of National Defense: namely, heavier-than-air flying machines.

In the afternoon the Section, on special train, visited the works of The Burgess Company at Marblehead, Mass., where the visitors were shown about the plant and given very frank and thorough explanations by the engineers of the company.

The Burgess Company was originally started by Mr. Burgess to manufacture, in this country, the Dunn self-stabilizing aeroplane, but is now making aeroplanes for The Curtiss Company, practically exclusively on orders from the Federal Government and units affiliated with it.

The visiting engineers were shown all over the place, and had a chance to inspect, both in their final shapes and in various stages of construction, hydroaeroplanes and land machines of various types. In the water, just ready to start for its altitude test previous to acceptance by the Federal Government, was a huge Dunn-type hydroaeroplane specially built for carrying out experiments with the John Hays Hammond method for the wireless direction of torpedoes. And right by, in the shed, suspended from the ceiling, was what is probably the smallest seaplane in the world, a tiny machine in which every other consideration except safety is sacrificed for speed, and which can develop 95 miles an hour without much trouble.

While the explanations were given by Mr. Russell, Engineer of the Burgess Company, and various questions of the members answered, a big Dunn machine appeared in the air and circled overhead at a speed estimated at about 70 miles an hour. The interesting feature of that particular flight was the fact that, as stated by Mr. Russell, the pilot in it had only three hours of preliminary training.

The evening program comprised the meeting of the Section at Wentworth Institute, Boston, Prof. A. L. Williston, Mem. Am.Soc.M.E., in the chair.

Maj. W. P. Wooten, of the Corps of Engineers, U. S. A., was scheduled to speak, but was prevented through illness, and instead Judge M. J. Murray gave an impassioned talk on national unpreparedness, the conditions which confronted the United States expeditionary force in Mexico, and which confront its military establishment now. In conclusion, he called upon the engineers to stick to their work, but at the same time try to acquire the information which would prove useful to them, if called to actual service.

This address was followed by a talk on Wings for the American Eagle, by W. B. Stout, Chief Engineer, Aircraft Division, Packard Motor Car Company, Detroit. Mr. Stout called attention to the great change which the automobile wrought in the state of mechanical education of the average public. Twenty years ago the average man hardly knew what a monkeywrench was used for, and let his wife oil the sewing machine. At present, there are actually in the country hundreds of thousands of men in various walks of life who can understandingly take care of the rather complicated mechanical and electrical equipment of an automobile. The automobile not only educated the public in the fundamentals of machinery, but also taught alertness to men who were formerly largely dreamers. The aeroplane is going to continue what the automobile began and, in fact, is already teaching its users entirely new conceptions of space and motion. Man is rapidly becoming a real three-dimensional being; and as the speaker expressed it, a new heaven is being opened through the aeroplane, just as a new earth was made by the automobile.

In the course of his address Mr. Stout gave some interesting statistical data on the present aircraft activities in Europe. He stated that aeroplanes are now made to climb steadily at the rate of 1000 ft. per min. and upward and there is in the field a small Italian machine which can climb at an angle of 45 deg. The development of aeroplane construction is so rapid that a new type of aeroplane is created on the average of about every eleven weeks, and it is by no means rare that when a batch of machines come from the factory, on orders placed only three or four months before, the planes are found to be antiquated to such an extent that they are simply burned up without being used at all. The production of machines has reached the impressive figure of 1000 machines a week, and the only real limitation to a still greater production is the problem of the engines.

ROLL OF HONOR

THE Committee on Engineer Officers' Reserve Corps, now the Committee on National Defense, has just issued to the membership two circulars giving instructions to those who contemplate offering their services in the Army and Navy. The Committee requests that those members who apply for appointments in the national service, report this fact to the Society, so that their names may be included in the Roll of Honor and so that the Committee may keep track of the men.

Last month we published the first list of those members of the Society who had enlisted in the national service, and we supplement that with the following names since received:

BARKER, GEORGE S., Coast Artillery, Officers' Reserve Corps.*
BELCHER, P. W., First Lieutenant, Engineer Officers' Reserve Corps.
CATTELL, WILLIAM A., Major, Engineer Officers' Reserve Corps.
CAMPBELL, E. D., Captain, Engineer Officers' Reserve Corps.
CONARD, FREDERICK U., Second Lieutenant, Engineer Officers' Reserve Corps.
CRONEMEYER, HENRY C., Captain, Engineer Officers' Reserve Corps.*
ENNIS, WILLIAM D., Major, Officers' Reserve Corps (Ordnance Dept.).
FARRINGTON, THOMAS H., Captain, Engineer Officers' Reserve Corps.*
FRANCIS, HARRIS S., Lieutenant, Engineer Officers' Reserve Corps.*
GLENN, EDWARD R., First Lieutenant, Engineer Officers' Reserve Corps.*
HARRIS, MURRAY W., Ordnance Dept., Officers' Reserve Corps.*
HECHLER, F. G., Mechanical Engineer, United States Naval Engineering Experiment Station, Annapolis, Md.
HILL, EDWARD L., Captain, Engineer Officers' Reserve Corps.*
HOBART, J. C., Jr., First Lieutenant, Engineer Officers' Reserve Corps.*
HOLCOMBE, AMASA M., Captain, Officers' Reserve Corps.
HULBURT, WYNNE D., Second Lieutenant, Engineer Officers' Reserve Corps.*
JONES, REID, Captain, Engineer Officers' Reserve Corps.*
LACY, ROBERT, Captain, Engineer Officers' Reserve Corps.*
LEISTNER, AUGUST, First Lieutenant, Engineer Officers' Reserve Corps.*
LONN, J. M., Reserve Officer, Engineer Officers' Reserve Corps.*
McNEAL, D. RAYMOND, Engineer Officers' Reserve Corps.*
MERKT, THEO. B. J., Ordnance Dept., Officers' Reserve Corps.*
MULLER, RAYMOND W., Mechanical Engineer, Engineer Officers' Reserve Corps.*
RATHJENS, GEORGE W., Captain, Engineer Officers' Reserve Corps.
RHYS, C. O., Captain, Engineer Officers' Reserve Corps.*
ROSS, HENRY B., First Lieutenant, Engineer Officers' Reserve Corps.*
STREETER, ROBERT L., Major, Officers' Reserve Corps.*
STUART, THOMAS E., Central Department, Engineer Officers' Reserve Corps.*
TAYLOR, CHARLES F., First Artillery, Officers' Reserve Corps.
THORNHILL, THEODORE W., First Lieutenant, Engineer Officers' Reserve Corps.*
TRIMMER, JAMES W., Ensign (Engineer), U.S.N.R.F., Class 2.
VAN VALKENBURGH, MERRITT, Ordnance Dept., Officers' Reserve Corps.*
WEINBERG, GEORGE S., Major, Engineer Officers' Reserve Corps.*
WIEBER, GEORGE A., Second Lieutenant, Officers' Reserve Corps.*
WILBER, DANA W., Captain, Engineer Officers' Reserve Corps.
YODER, THOMAS M., Captain, Officers' Reserve Corps.

Coöperation with Bureau of Mines

The Society's Standing Committee on Research has been appointed a Special Advisory Committee of the U. S. Bureau of Mines, and the following Sub-Committees have also been appointed to coöperate with the Bureau:

Sub-Committee on Mining Equipment:

FREDERICK K. COPELAND, *Chairman*, President, Sullivan Machinery Company, 122 S. Michigan Ave., Chicago, Ill.

FRANK H. ARMSTRONG, Mechanical Engineer, Penn Iron Mining Company, Republic Iron Company, Vulcan, Michigan.

DOUGLAS BUNTING, Chief Engineer, Lehigh & Wilkes-Barre Coal Co., Wilkes-Barre, Pa.

Sub-Committee on Fuels:

CHARLES RUSS RICHARDS, Professor of Mechanical Engineering, University of Illinois, Urbana, Illinois.

JOSEPH HARRINGTON, Advisory Combustion Engineer, 208 S. La Salle St., Chicago, Illinois.

CHARLES J. BACON, Engineering Department, E. I. du Pont de Nemours & Co., Wilmington, Delaware.

Our Members and National Service

The members of this Society, in common with those of the three other Founder Societies, received during the past month from the Joint Engineer Committee on National Defense, formerly the Joint Committee on Engineer Reserve Corps, two pamphlets instructing them how best to apply for service in the military and naval forces of the United States.

Reviewing the pamphlet describing the Army service, it appears that the general place for the members of our Society is as officers in the Ordnance Department of the Officers' Reserve Corps, as the following extracts show:

ORDNANCE DEPARTMENT

Officers of the Ordnance Department of the Army are mechanical engineers especially trained for the production of war munitions. The Department offers one of the best fields in which mechanical engineers can serve as reserve Ordnance officers in the Officers'

* Acceptance of commission pending at date of latest list from War Department.

[illegible] engineers, chemists and [illegible] expert assistance to the Depart- [illegible] may therefore be of [illegible]

[illegible] definite form, it is [illegible] divided into groups, [illegible] particular arsenal which [illegible] that group, to which [illegible] during the active period [illegible]

[illegible] is charged with the duty of procuring [illegible] and distributing the necessary ord- [illegible] the Army and the Organized M[illegible] establishes and maintains arsenals [illegible] and safekeeping.

[illegible] include cannon and artillery [illegible] as the great guns used in the sea- [illegible] with their carriages, as well as the lighter guns [illegible] artillery; apparatus and machines for the [illegible] of artillery; small arms, ammunition, and [illegible] equipments and harness for the artillery, and [illegible] for cavalry and for all mounted men except those of the Quartermaster Corps; tools, machinery, and materials for the ordnance service; and all property of whatever nature supplied to the military establishment by the Ordnance Department.

The duties of Ordnance officers are generally those connected with the direction, management, control and supervision of the work of manufacture, test and repair of ordnance and ordnance stores at manufacturing arsenals and depots, with the issuing and receiving of such supplies and with the inspection and test of such materials when purchased by contract.

Applicants for the Officers' Reserve Corps, Ordnance Section, desiring technical duty should have both a theoretical and practical knowledge of steam boilers, engines, shop tools, including the handling of such tools; electricity and electrical machines, particularly dynamos and motors; and experience in the manufacture of articles composed of steel, of wood, and of leather.

They should have had practical experience in the management of shops and the handling of employees. Their experience should also be such as to enable them to take up the work of inspection of all classes of ordnance stores if manufactured by private concerns under contract, to insure that such materials are of standard design and workmanship and in accordance with Ordnance Department drawings and specifications.

Full information regarding the Corps, may be obtained from the Adjutant General, United States Army, Washington, D. C., as the pamphlet states.

The booklet describing service in the Navy states that members of the engineering societies are probably best fitted to serve in the Naval Coast Defense Reserve, full particulars of which are given in a pamphlet entitled Circular Relating to Enrollment in the Naval Coast Defense Reserve, to be obtained by addressing the Commandant of any Naval District.

The U. S. Bureau of Mines, in coöperation with the American Institute of Mining Engineers and the American Chemical Society, has undertaken a census of mining engineers, metallurgists and chemists with a view of ascertaining the qualifications of each and the line of work in which each can be of the most service to the country in time of emergency. The classification will embrace 27 specific groups of industrial chemists, 16 groups of engineering specialists, and 15 groups in the metallurgical field. By such minute classification the bureau will be in a position to furnish on short notice the names of specialists for service under the classification, so that in case of necessity these technical men can be available to industrial plans where they would be of most assistance to the country. European experience has shown that nothing is more important in time of national emergency than a knowledge of the qualifications and experience of expert technical men.

Request for January Issues

The demands for copies of the January 1917 issue of THE JOURNAL, which contains a full account of the 37th Annual Meeting, have now exceeded the supply, and this issue is temporarily out of stock. Requests for copies are still being made, however, and members who do not desire to preserve permanently their copy of the January JOURNAL are requested to return it to the Secretary, who will remit postage and cost to them.

Commission on Gunmounts

The following is the personnel of the Commission to determine the style on gunmounts for the U. S. Army: Gen. Joseph E. Kuhn (of the Line), President of the War College; Col. Charles B. Wheeler from the Ordnance Department, formerly head of the Watertown Arsenal; two representatives of the Coast Artillery, Major John W. Gulick from Fortress Monroe and Capt. Walter R. Wilson; representative from the Navy, Capt. Charles P. Plunkett; the two civilian appointees from the Am.Soc.M.E., Dr. Ira N. Hollis and Dr. D. S. Jacobus.

In an editorial under date of April 12, 1917, the *Iron Age* discusses the utilization of slags from steel-making processes. From statistics adduced it appears that each year in the United States over 2,000,000 tons of basic slag is obtained from basic open-hearth steel furnaces, and in this slag is contained not less than 111,000 tons of oxide of manganese.

The loss is estimated by one producer to amount to $8 per car for each car dumped, or a total loss of $320,000 per year if all the country's basic slag is discarded; and when it is recalled that the railroads now charge for removing all slags this matter becomes still more serious. The value of acid slag is much less.

The utilization of slag in blast-furnace burdens appears to be promising, but the writer does not think much of the use of slag as a source of metallic manganese or substitute for ferromanganese.

Lawrence V. Benet, Mem.Am.Soc.M.E., vice-president of the Société Anonyme des anciens Etablissements Hotchkiss & Cie., Paris, France, is coming to this country as the representative of the American Chamber of Commerce in Paris, of which he is president. He is accompanying M. André Tardieu, the newly appointed French High Commissioner to the United States, who has gathered elaborate statistics of the requirements of France for presenting detail information to the American authorities. M. Benet is the Paris representative of our Special Committee on International Standard Pipe Threads.

Construction of a new building for the Engineers' Club, Dayton, Ohio, will be begun shortly and is expected to be finished by January 1. It will cost about $170,000, of which $130,000 is for the building alone. It will be two stories high, with basement, of Georgian design, of buff gray brick and with carved stone trimmings.

Oil engines working at high altitudes cannot develop the same power as at sea level owing to the smaller weight of oxygen contained in the cylinder.

The Use of Bessemer Steel Boiler Tubes as a Substitute for Tubes of Open-hearth Steel as Required by the A. S. M. E. Boiler Code

As a result of the unprecedented demand for steel and its present scarcity, efforts have been made to provide for the use of boiler tubes manufactured of bessemer steel in place of the open-hearth steel tubes as required by the A.S.M.E. Boiler Code. The National Tube Company, in a letter addressed to the trade early in March, requested that wherever possible bessemer steel tubes be used in place of those made of open-hearth steel in order to relieve the pressure of demand upon this latter material. It was pointed out in this letter that the present industrial situation has led to a demand for tubes of the open-hearth material which had grown to such an extent that the company was nearly two years behind in its orders, and the use of bessemer steel was suggested as a means of relief.

The impression was given that this was an attempt to replace the material required by the Boiler Code by an inferior material. The matter was brought before the Council of the Society at a meeting on March 16, with the result that a Committee was appointed to confer with the National Tube Company. This Committee consisted of the following members:

Ira N. Hollis, President, American Society of Mechanical Engineers.

Charles S. Blake, Hartford Steam Boiler Inspection & Insurance Co.

J. B. Ennis, American Locomotive Co.

E. R. Fish, Heine Safety Boiler Co.

F. R. Hutton, American Museum of Safety (Member of Council).

Julian Kennedy, Member of Council.

Frank E. Law, The Fidelity & Casualty Co.

J. W. Lieb, National Electric Light Assn.

Geo. A. Orrok, National Electric Light Assn.

W. M. McFarland, Babcock & Wilcox Co.

H. deB. Parsons, Consulting Engineer (Member of Council).

James Partington, American Locomotive Co.

H. V. Wille, Baldwin Locomotive Works.

Dr. Hollis appointed Mr. H. deB. Parsons Chairman of the Committee.

Meetings were held by this Council Committee in conference with officials of the National Tube Company in which the entire situation was thoroughly canvassed and efforts were made to outline a proper solution of the problem. The Council Committee pointed out the unquestionable advantages of open-hearth steel as compared with bessemer steel for use in boiler tubes, and urged upon the Company the necessity of exerting its greatest effort to cope with the situation. Inasmuch as the National Tube Company had been instrumental in assisting to develop the present boiler-tube specifications contained in the Code, and as these specifications had been found to work out satisfactorily, it was felt that to abandon the requirement of open-hearth steel would be a retrograde movement. The officials of the National Tube Company explained that this suggestion was merely an effort on their part to point out a means of relief for those cases where it could be taken advantage of without conflicting with rules or requirements based on the A.S.M.E. Code. This statement was supplemented by one to the effect that efforts were being made to rush to completion additional open-hearth-steel furnaces which would undoubtedly be in operation in the middle of the summer and which would then greatly increase the open-hearth-tube-producing capacity of their works. It was further stated that the tube-manufacturing capacity of the Company was far in excess of the capacity of their sources of material supply.

The result of the conferences was a thorough understanding between the National Tube Company and the Council Committee relative to the situation. Assurances were given that there was no intent to sell tubes of bessemer material with the claim that they conform to the specifications of the A.S.M.E. Boiler Code, and a circular letter was drafted by the National Tube Company to be sent out by its branch offices to counteract any erroneous impression that may have been given. The letter was submitted to the Council Committee and with slight modifications it was agreed to by the Committee and was finally approved by the Council in the following form:

National Tube Company
Pittsburgh, Pa.

April 16, 1917.

Circular Letter No. 857

To Manager of Sales.

Gentlemen:

As you are aware, about four years ago we decided to in future manufacture all of our boiler tubes from open hearth steel. This action was taken because our experience had taught us that for locomotive boilers and for water tube boilers the open hearth steel tube was better than the Bessemer steel tube. For fire tube boilers we have never had any experience that leads us to believe one is any better than the other, but in order that our output might be satisfactory for all purposes we decided to make all tubes from open hearth steel. Later on a code was prepared by The American Society of Mechanical Engineers covering this whole question both as to material and gage. We gave our hearty coöperation to this Society to bring about the change which they proposed, and we have been coöperating with them in the various states so that this code should be the universal code throughout the United States, it being our firm conviction that boilers with all their appurtenances made under the code of that Society are preferable to those made under any other code heretofore in use. A situation has now arisen due to the war in Europe that has made it impossible for us to secure enough open hearth steel for this purpose, and we are pressed as never before for delivery of tubes. Up to the present moment we have endeavored to supply ourselves with enough open hearth steel to fill our orders for locomotive tubes and for tubes for water tube boilers, and have succeeded fairly well. We have been obliged, however, to ask many of our customers, who insisted upon deliveries that we could not make if we depended upon open hearth steel, to accept tubes made from Bessemer steel so that we could give the greatest possible service in enlarging the power of the country. The information regarding our desire to supply Bessemer steel tubes where the customer would agree to it has not been conveyed generally in the same manner, and an impression has gotten abroad that we are endeavoring to avoid the code of the A.S.M.E. and is causing us some embarrassment as well as the members of that Society. I wish therefore that you would issue this letter verbatim in circular form to your customers, one and all, that each may understand the situation just as it is. If they do, we feel quite sure that, where they are not called upon to supply boilers in accordance with the A.S.M.E. Code, they would readily agree to accept Bessemer, and if they do it will enable us, until we can supply ourselves with a full amount of open hearth steel, to run our furnaces full and for the general good. Just when we will be able to go back fully to the use of open hearth in the manufacture of boiler tubes I am unable at this writing to say, but we are rushing the construction of some additional open hearth furnaces and if nothing unforeseen occurs we expect by July to be able to supply our requirements, and if so we shall do so because we believe it altogether the best practice.

Yours truly,

1st Vice-President.

WILLIAM LODGE

WILLIAM LODGE, President of the Lodge & Shipley Machine Tool Company, of Cincinnati, Ohio, passed away at his home on Monday, April 30. His death was sudden and came as a great surprise to his many friends, since less than a week before he was in attendance at the annual convention of the National Metal Trades Association in New York City, where as usual he was one of the leading spirits.

Mr. Lodge was born in Leeds, England, in 1848, the son of George Lodge, a skilled mechanic in the textile industry. He had the advantages of what we call a common school education. After serving his apprenticeship in the shops of Fairbairn & Company, Leeds, he came to Philadelphia, where he worked for Chambers Brothers from 1869 to 1872, making paper-folding machinery. He came to Cincinnati in 1872 and worked for Steptoe, McFarlan, Nottingham & Co. for eight years, first as a journeyman machinist and later as a foreman. Having saved $1,000, he formed a partnership with William Barker, under the title of Lodge & Barker, at Fifth street at the junction of the C. H. & D. tracks, and they started in business the first day of January, 1880. Associated with them for a short time was Mr. Bechle, another Steptoe workman. Their first task was to true up a few second-hand machines which they had bought, and since they had no one in their employ, they were obliged both to secure their own orders and to execute them. Part of this first business was making some opening dies for Powell and a small turret lathe for the Lunkenheimer Company. The latter immediately ordered three more, and during the following year eighteen lathes were made and sold. Beginning with $1,000, the business inventoried at the end of the first year $7,000; at the end of the second year $32,000; and at the end of ten years $400,000. Fifteen months after starting they employed 75 men. There is little doubt that this rapid success induced quite a number of the better and more ambitious mechanics in Cincinnati to take up similar work. Mr. Lodge was well known among the mechanics of the city and had been president of their union. If one of their number could build up a successful business, why could they not do the same? Some of the best known of the Cincinnati tool-building firms were established during the few years after Mr. Lodge's start.

Wm Lodge

In 1886 Mr. Barker sold his interest to Charles Davis. Lodge and Davis continued in partnership until 1892, when Mr. Lodge severed his connection with the firm and it later became the American Tool Works. They were employing at that time between 300 and 400 men. Mr. Lodge, in March, 1892, organized the Ohio Machine Tool Company, and in August, 1892, became associated with Murray Shipley, forming the present The Lodge & Shipley Machine Tool Company.

Mr. Lodge's first export order was received in 1889. Alfred Herbert, who had just started in Coventry, sent an inquiry in regard to drill presses to Cincinnati, which was forwarded to Mr. Lodge in London. Mr. Lodge went down to see him and asked whether the inquiry was for the purposes of information or for purchase. Mr. Herbert said that if Lodge had a better machine he would buy. Mr. Lodge asked to see his machine and after a little hesitation he was taken out into the shop. The first machine he saw was a planer. He said he could save thirty per cent on the work as it was being done, and would sell them a machine which would do it for £100. He was told that the planer they were looking at cost only £65, and replied that that was all it was worth. He spent several hours in the shop and left the plant not only with an order but with the check in payment thereof. This was the beginning of a large export business.

While the firm was Lodge & Davis, it built lathes, planers and drill presses. Mr. Lodge wanted to manufacture rather than build, and to specialize upon lathes. Mr. Davis, who was a business man, wanted a complete line of tools, as he saw the opportunity of selling other machines with the lathes. This led to the policy of concentrating upon the manufacture of engine lathes, and placing orders for other types of tools with mechanics just starting up, or with workmen from their own plant whom they helped to start in business. For instance, to Smith & Mills, who had been foremen with John Steptoe and had started making set screws and cap screws, they gave an order for 300 shapers. To R. K. LeBlond, who had served his apprenticeship with Brown & Sharpe Manufacturing Co., and had come to Cincinnati to make printers' machinery and supplies, Lodge & Davis gave a large order for slide-rests. To William Owen, one of their workmen, they gave an order for Fox monitors. Owen went into partnership with Philip Montanus and started the Springfield Machine Tool Company, and Lodge & Shipley bought their entire product for eight years. Through Mr. Lodge's influence, Frank Kempsmith came from Warner & Swasey as one of the partners in this firm. He afterwards moved to

Milwaukee and started the Kempsmith Manufacturing Company.

Mr. Lodge had, during his apprenticeship in the shops of Fairbairn & Co., where specialization of manufacture was carried out to a marked degree, completely absorbed the idea of the manufacture of machinery in large lots. He was particularly well known for the fact that he was one of the first, if not the first, to specialize in the manufacture of one type of machine tool only, instead of making a few of many kinds of machine tools.

Some of the firms whose principals have in one way or another been associated with Mr. Lodge are the Fosdick Machine Tool Company, Boye & Emmes Machine Tool Company, Dreses, Mueller and Company and the Cincinnati [illegible] Company.

Mr. Lodge was a member of The American Society of Mechanical Engineers for 27 years, was a member of the Engineers' Club of Cincinnati, the Machinery Club of New York, the Ohio Manufacturers' Association and various other organizations; and was especially active in the National Metal Trades Association, of which he was treasurer for [illegible] years. He was one of the organizers of the National Machine Tool Builders' Association and served as its president for [illegible] years.

CANDIDATES FOR MEMBERSHIP

TO BE VOTED ON AFTER JULY 10, 1917

THE American Society of Mechanical Engineers is an organization for mutual service of over 7800 engineers and associates coöperating with engineers. The membership of the Society comprises Honorary Members, Members, Associates, Associate-Members and Juniors, all elected by ballot of the Council. Application for membership is made on a regular form furnished by the Secretary which provides for a statement of the standing and professional experience of the applicant and requires references from voting members personally acquainted with the applicant. The requirements for admission to the various grades will be furnished upon request.

Below is the list of candidates who have filed applications for membership since the date of the last issue of The Journal. These are classified according to the grades for which their ages qualify them, and not with regard to professional qualifications, i.e., the ages of those under the first heading place them under either Member, Associate or Associate-Member, those in the next class under Associate-Member or Junior, and those in the third under Junior grade only. Applications for change of grading are also posted.

The Membership Committee, and in turn the Council, urge the members to scrutinize this list with care and advise the Secretary promptly of any objections to the candidates posted. All correspondence in this regard is strictly confidential. Unless objection is made to any of the candidates by July 10, 1917, and providing satisfactory replies have been received from the required number of references, they will be balloted upon by the Council. Those elected will be notified about August 15, 1917.

NOTE. The Council desires to [illegible] upon applicants for membership that under the present national conditions the procedure of election of members may be somewhat slower than under normal conditions. The first step in the consideration of an application is taken by the Membership Committee and this committee is composed of [illegible] fewer opportunities to meet together in these strenuous times.

NEW APPLICATIONS

FOR CONSIDERATION AS MEMBER, ASSOCIATE [illegible]

California

HANSON, FRED P., Shop Superintendent and Engineer
American Gold Dredging Co., [illegible]

KEY, JAMES F., President,
Key Adding Machine Co., Los Angeles

KILGORE, EDWIN R., Division Superintendent Pipe Line Department,
Standard Oil Co., Patterson

LAMPMAN, JAY B., Assistant General Sales Manager,
Worthington Pump & Machinery Corp., Los Angeles

ROLPH, GEORGE M., General Manager,
California & Hawaiian Sugar Refining [illegible], San Francisco

Colorado

SALISBURY, ROYAL D., Consulting Engineer, Denver

Connecticut

ANDERSON, ROBERT E., Production [illegible],
Winchester Repeating Arms Co., New Haven

BLAKESLEE, RUSSELL C., Mechanical Superintendent,
Chase Metal Works, Waterbury

DART, HARRY E., Superintendent Engineering Department,
The Hartford Steam Boiler Inspection & Insurance Co., Hartford

HENDERSON, GEORGE A., [illegible] Machine Shop,
Winchester Repeating Arms [illegible], New Haven

KANN, H. E. ARTHUR, [illegible],
Winchester Repeating Arms [illegible], New Haven

Georgia

KLEIN, EDWARD W., Heating Engineer,
Bishop Babcock Becker C[illegible], Atlanta

Illinois

McELROY, JOSEPH W., [illegible] Engineer,
Westinghouse Elec. & Mfg. Co., Chicago

NOLTE, CHARLES B., Mechanical Engineer,
Robert W. Hunt & Co., Chicago

SAVERY, THOMAS H., JR., Consulting Engineer, Chicago

SHIELDS, HARRY C., Western Sales Engineer,
[illegible] Engineering Co., Chicago

WEBER, FRANK E., Industrial Engineer, Chicago

Indiana

GRIMES, [illegible] L., Engineer and Superintendent,
Johnson & Miller [illegible], Terre Haute

Kentucky

HOUSTON, HERMAN M., Secretary and Treasurer,
The Houston Stanwood & Gamble Co., [illegible]

Louisiana

MOODY, HOWARD N., [illegible] Engineer, New Orleans

Massachusetts

CHAPMAN, ALBERT P., Superintendent Power and Repairs,
Ludlow Mfg. Associates, Ludlow

HEALD, JAMES N., Treasurer and General Manager,
The Heald Machine Co., Worcester

MARTIN, GEORGE R., Assistant General Manager,
American Steam Gauge & Valve Mfg. Co., Boston

Michigan

HEWITT, RICHARD D., Secretary-Manager,
General Fire Extinguisher Co., Detroit

MEDHURST, ARTHUR W., Assistant General Factory Manager and Mechanical Engineer,
Anderson Electric Car Co., Detroit

SQUIRES, [illegible], Consulting Engineer,
Signal Motor Truck Co., Detroit

Minnesota

EMERSON, George H., General Manager,
Great Northern Railway Co., St. Paul

Missouri

BATEMAN, Paul, Assistant Chief Estimator,
American Car & Fdy. Co., St. Louis

LILJEGREN, Gunnar O., Manager Sprinkler Department,
Urbauer Atwood Heating Co., St. Louis

New Hampshire

FLATHER, Ernest J., President and Treasurer,
E. J. Flather Mfg. Co., Nashua

TILTON, Henry B., Superintendent and Works Manager,
Morley Button Mfg. Co., Portsmouth

New Jersey

ACKERMAN, Albert A., Jr., Chief Draftsman,
The Singer Manufacturing Co., Elizabethport

BROWN, Albert F., Engineering Assistant, Mechanical Dept.,
Public Service Elec. Co., Newark

BURDICK, Herbert, Designing Engineer, Chief Draftsman,
DeCamp & Sloan, Inc., Newark

HOWARD, Arthur E., Manager Rate Service Dept.,
T. A. Edison Affiliated Interests, Orange

MUSSO, Alfred, Factory Consulting Engineer,
Edison Battery Co., Orange

PATTERSON, Edgar H., Assistant to Chief Engineer,
New York Shipbuilding Corp., Camden

New York

CHAMBERLAIN, William T., Chief Draftsman,
Standard Aniline Products, Inc., Wappingers Falls

HALL, Charles R., Manager Mechanical Sales Dept.,
Diamond Rubber Co., New York

LAENCHER, Frederick W., Chief Engineer,
W. C. Ritchie & Co., Brooklyn

LOCKWOOD, Marquis H., Mechanical Expert and Patent
Attorney, New York

MANNING, James H., Superintendent Motive Power,
The Delaware & Hudson Co., Watervliet

MULCARE, James J., Assistant Engineer in Charge Drafting
Dept., General Electric Co., Schenectady

QUIRK, Clinton H., Engineer,
Howard & Morse, New York

ROBINSON, Thomas R., Engineer,
W. S. Barstow & Co., Inc., New York

ROWLAND, George R., Supervising Engineer, Lubricating Div.,
The Texas Co., New York

STAFFORD, Hal R., Mechanical Engineer,
Economy Devices Corp., New York

STRATTON, David V., Production Manager,
Pyrene Manufacturing Co., New York

North Carolina

STATES, Louis A., Consulting Engineer, Gastonia

Ohio

CORDON, Byron B., Scale Inspector,
Pennsylvania Lines West, Columbus

SHIPLEY, Murray, Vice-President and Secretary,
The Ledge & Shipley Mch. Tool Co., Cincinnati

SNYDER, Herbert W., Assistant to Vice-President,
Lima Locomotive Works, Inc., Lima

Pennsylvania

BOYD, Frank F., Consulting Engineer,
Ballinger & Perrot, Philadelphia

CHURCH, Arthur L., Assistant to President,
The Baldwin Locomotive Works, Philadelphia

HAARBYE, Storm B., Assistant Engineer,
American Sheet & Tin Plate Co., Pittsburgh

JAMES, Richard L., Constructor,
The United Gas Improvement Co., Philadelphia

KENYON, John T., Consulting Rifle Expert,
Remington Arms Co., Delaware, Eddystone

LAWRENCE, John S., Manufacturing Superintendent, Erie Works,
General Electric Co., Erie

LINNING, Frank, Works Manager,
Tacony Steel Co., Tacony

MAHONEY, Joseph N., Engineer with
Westinghouse Elec. & Manufacturing Co., Pittsburgh

RASCHE, Charles M., Superintendent Toolroom,
Remington Arms Co. of Del., Eddystone

SELKIRK, William M., Chief Engineer,
Pittsburgh Steel Products Co., Monessen

STETSON, John B., Jr., President,
Defiance Manufacturing Co., Philadelphia

Utah

LEDDELL, William A., Engineer,
United States Smelting, Refining & Mining Co., Salt Lake City

Virginia

MAST, Frank H., President & Treasurer,
Atlantic Iron Works, Inc., Norfolk

Vermont

LOVEJOY, Fred P., President,
Lovejoy Tool Co., Inc., Springfield

Wisconsin

CORWIN, Lloyd A., Efficiency Engineer,
Four Wheel Drive Auto Co., Clintonville

Canada

MACDOUGALL, George D., Chief Engineer,
Dominion Iron & Steel Co., Sydney, N. S.

MELDRUM, Malcolm R., General Manager,
The Herbert Morris Crane & Hoist Co., Ltd., Toronto

PAIGE, James F., General Manager,
Port Arthur Shipbuilding Co., Ltd., Port Arthur, Ont.

Hawaii

RAMSAY, William A., Manager,
Catton, Neill & Co., Ltd., Honolulu

FOR CONSIDERATION AS ASSSOCIATE MEMBER OR JUNIOR

California

GUHA, Kamini K., Student, University of California, Berkeley

KASPAR, Joseph J., Structural Engineer,
Llewellyn Iron Works, Torrance

Connecticut

BANKS, Frederick R., Engineer of Equipment (Commercial
Division) Remington Arms,
U. M. C. Co., Bridgeport

Illinois

NECROLOGY

ORVILLE G. BENNET

Orville G. Bennet was born in New York City on August [illegible] 18[illegible]. He received his early education in the Horace Mann School and was graduated from Cornell University in 1904.

His first position was with Westinghouse, Church, Kerr & Co. He left that firm to become associated with the Ingersoll-Rand Drill Company, where he remained till 1906, when he accepted a position with the American Trading Company, representing that company in Japan until 1909, chiefly in the sale and installation of mining machinery. Not wishing to become permanently identified with the Orient, he resigned in 1910 to accept a position with the Akonite Company, New York City. In 1911 he took over the management of the export business of the General Motors Company, later becoming president and general manager of the company. He resigned this position in 1916, and at the time of his death was organizing a company for the distribution of the output of the Nash Motors Company in the state of Texas.

He became a junior member of the Society in 1907. He died February 28, 1917.

EDWIN J. HADDOCK

Edwin J. Haddock was born in Mount Vernon, N. Y., June 13, 1868. He was educated in the schools of New York City. He obtained his early experience in the shops and drafting rooms in the vicinity of New York, completing this training with seven years spent under the immediate direction of Thomas A. Edison.

He held successively the positions of chief draftsman of the Robins Conveying Belt Company, New York City; chief engineer of the Jeffrey Manufacturing Company, Columbus, O., and chief draftsman of the Tennessee Coal, Iron and Railway Company, Birmingham, Ala. Later, he engaged in private practise in Milwaukee, Wis., building numerous stone-crushing plants in that region. At the time of his death he was chief engineer of the Edgewater Steel Company, Pittsburgh.

He became a member of the Society in 1906. He died April 11, 1917.

CLINTON A. HAMILTON

Clinton A. Hamilton was born on October 5, 1873, at East Orange, N. J. He was a graduate of the high school of East Orange. He served a three-years' apprenticeship in the E. P. Allis Company's shops at Milwaukee, and then went to Pittsburgh to take a position with the National Tube Company. When he severed his connection with this firm he entered into consulting engineering in New York City, under the firm name of McClave, Hamilton & Remmer. Later he became general sales manager for the International Steam Pump Company, with headquarters at Pittsburgh. In 1906 he accepted the position of vice-president and general manager of the Wisconsin Engine Company, Corliss, Wis., and remained with this company for about six years, resigning to accept the position of vice president and general manager of the Lavine Steering Gear Company, Racine, Wis. In 1913 he became president and general manager of the Racine Manufacturing Company, and retained this position until 1916, when he formed a partnership with Mr. James Cram and took over the sales agency of the Allen Motor Car Company. He was connected with this company at the time of his death.

He became a member of the Society in 1908. He died on March 12, 1917.

JOHN SEDGWICK HYDE

John Sedgwick Hyde was born in Bath, Me., March 25, 1867. He was a graduate of the Massachusetts Institute of Technology, class of 1888. He was connected with the Bath Iron Works, Ltd., in the successive capacities of apprentice, draftsman, paymaster, assistant superintending engineer, superintendent, vice-president and general manager and since 1905 as president of that company. He was a director of the Maine Central Railroad.

Mr. Hyde was a member of the New York Engineers' Club, Society of Naval Architects and Marine Engineers, American Society of Naval Engineers, and the Institution of Naval Architects of Great Britain. He became an Associate of the Society in 1892. He died at St. Augustine, Fla., March 17, 1917.

BRUCE C. McALPINE

Bruce C. McAlpine was born on June 2, 1872, at Pierceton, Ind. He received his early education in the high schools of Peoria, Ill., and Charlotte, Mich. From the latter he entered the Michigan Agricultural College, and was graduated from the mechanical-engineering course in 1905.

He entered the employment of George D. Walcott & Son, builders of machine tools at Jackson, Mich., as draftsman, and later became successively chief draftsman and general manager. Owing to changes in the ownership of the Walcott firm, he moved to Detroit, where he was engaged in the design of special tool equipment. In May 1913 he became chief draftsman and mechanical engineer for the Frost Gear & Forge Co., of Jackson, Mich., which position he held at the time of his death.

He became a member of the Society in 1914. He died on December 27, 1916.

WILLIAM F. MATTES

William F. Mattes was born on September 29, 1849, in Scranton, Pa. When seventeen years of age he was made superintendent of a small mining railroad near Mount Hope, N. J., and he continued in the iron-mining industry in New Jersey, and later in Virginia, until 1882, when he was made chief engineer of the Lackawanna Iron & Steel Works, of Scranton. In 1888 he became general manager of the West Superior Iron and Steel Works, West Superior, Wis. He was director of the First National Bank, president of the Manufacturers, Shippers' and Jobbers' Association, and park commissioner, of that city.

In 1893 failing health compelled him to move to Colorado, where he was interested in mining enterprises for several years. Later he returned to Scranton and was made chief engineer of the Lackawanna & Wyoming Valley Railroad Co. while

the Laurel line was in the process of construction. When his brother, Charles C. Mattes, died, he succeeded him as general manager of the Lackawanna Iron & Coal Co.

He was a member of the American Institute of Mining Engineers, The Franklin Institute, and the New York chapter of the Sons of the Revolution. He became a life member of the Society in 1882. He died on February 3, 1917.

EDWARD J. MARTIN

Edward J. Martin was born at West Roxbury, Mass., September 7, 1882. He was educated in the public schools of Boston. He then served an apprenticeship as machinist. He was a graduate of the mechanical engineering course of the International Correspondence Schools, and also of the Emerson Institute of Efficiency. At the time of his death he was secretary and manager of the Connecticut Electric Manufacturing Company. He became an associate-member of the Society in 1915. He died on April 7, 1917.

LEWIS R. POMEROY

Lewis R. Pomeroy, well known as a consulting mechanical engineer, especially expert in matters relating to the construction, maintenance and efficiency of locomotives and the necessary shop equipment, died suddenly at his home in Orange, N. J., May 7.

Mr. Pomeroy was born at Port Byron, N. Y., February, 1857, and was graduated from the Irving Institute, Tarrytown, N. Y. He early entered the railroad field, where his work attracted considerable attention. From 1886 to 1890 he was a special representative of the Carnegie Steel Company, introducing basic boiler steel for locomotives and special forgings for railways. For nine years he was engaged in similar work with the Cambria Steel Company and the Latrobe Steel Company jointly. He then became connected with the Schenectady Locomotive Works as assistant to the general manager, a position he held until 1902.

During the following six years he was a special representative for the General Electric Company in the railway field, this work covering the electrification of steam roads and railway shops and general application of electricity to all railway purposes. Subsequently, for two years, he was assistant to the president of the Safety Car Heating and Lighting Company, leaving to become chief engineer of the railway and industrial division of J. G. White and Company. Late in 1911, he resigned to open an office in New York City as a consulting engineer. In 1914 he became associated with the U. S. Light and Heat Company as manager of the New York office. For the past year or so he had again been engaged in consulting work along lines in which he was qualified by his wide experience.

Mr. Pomeroy was possessed of an enormous fund of information, and was ever ready to give unprejudiced help of a most dependable character. He was serious-minded, yet always cheerful; prompt in action yet painstaking and thorough; delightful in companionship, yet loyal to his convictions.

He joined the Society in 1890 and was Chairman of its Membership Committee at the time of his death. He was also a member of the American Institute of Electrical Engineers, the American Master Mechanics Association, the Railroad Club of New York, the Engineers' Club of New York, and the New York Railroad Club.

WILLIAM C. WILLIAMSON

William C. Williamson spent his early youth in Philadelphia, attending high school there. After leaving school he began his engineering experience by associating himself with a jeweler and watchmaker in repairing watches. This work was not especially to his liking and so he apprenticed himself to the old firm of Reaney, Neafie & Co., at that time one of the foremost engineering firms of the entire Atlantic seaboard.

In 1861 he entered the United States Navy as 3rd assistant-engineer, serving throughout the war. He resigned June 10, 1866, to engage in the engineering business with his two brothers, founding the firm of Williamson Brothers. His engineering talents soon showed in the Williamson type of clutch and frictional-geared cargo hoists. In the early eighties he introduced in a ship building at the yard of the William Cramp and Sons Ship and Engine Building Company, for the Metropolitan Steamship Company of New York, a steam engine to supersede the old type of hand steering wheel for the control of ships. It was an immediate success and entitles him to be classed among the foremost naval engineers of his day.

He was prominent also in financial affairs, being one of the oldest directors of the Kensington National Bank, and director and vice-president of the Industrial Trust, Title and Savings Company of Philadelphia.

He was a member of the Naval Order of the United States, Post No. 2, G. A. R., and the Engineers' Club of Philadelphia. He was a member of the Society of long standing, having been elected to membership in 1882. He died December 2, 1916.

The present inability of farmers to raise more grain is due to the lack of sufficient farm power and the scarcity of farm labor. For farm power farmers are dependent upon either animal power (horses and mules) or tractors. But the animal power will necessarily decrease, owing to the demand of the army for horses and mules. Hence the necessity for the intelligent use of farm tractors on a large scale.

Statistics collected by the Bureau of Farm Management of the Department of Agriculture show that there are now available in the United States approximately 35,000 tractors.

The limiting factors in the production of tractors are today the shortage of materials, machine tools and labor. The Government has been asked by the Tractor Standards Division of the S.A.E. to devise means whereby the tractor manufacturers can be furnished with the materials, machine tools and labor in suitable quantities.

Tentative plans for an organization to be known as the National Committee of Industrial Safety, to act as an auxiliary to the advisory commission of the Council of National Defense, were drawn up at a meeting under the auspices of the American Museum of Safety in New York, Tuesday, April 24. The committee is to have 15 members, selected because of activities in fire protection, structural safety, dust and fume control, etc. Among those already named are: Colonel T. L. Bryant, Arthur H. Young, Lew R. Parmer, C. L. Close, Dan H. Manning, M. A. Dow, Robert B. Kohn, J. L. Mauran, Owen Brainard, Elmer Jensen, and D. Everett Waid. Headquarters will be in the Octagon Building, Washington. (*Daily Iron Trade and Metal Market Report*, vol. 7, no. 82, April 26, 1917, p. 4)

AMONG THE SECTIONS

THE Entertainment Committee of the New York Section made very complete arrangements for the Annual Social Evening which was held in the large dining hall of the Machinery Club, New York City. The speakers of the evening were Edwin J. Prindle, Toastmaster; President Ira N. Hollis, Commander E. P. Jessop, and John J. Swan. All of the speeches related to the part of the engineer in the enormous task confronting the country in the war. These are busy times and a large percentage of the New York membership were evidently unable to attend; nevertheless those present were well rewarded as the occasion was a most enjoyable one. The Entertainment and Acquaintanceship Committees of the New York Section have been doing excellent work in providing opportunity for more of the "human element," and the committees are to be congratulated upon their latest success.

THE FIRST SECTION IN CANADA

The first Section of the Society outside of the domain of the United States was established recently at Toronto, Canada. The Council at its April meeting approved the petition of the members of the Society in the Province of Ontario for permission to hold meetings.

The Executive Committee of the Ontario Section, as it will be known, is: G. V. Ahara, Prof. R. W. Angus, C. R. Burt, L. H. Fletemeyer and C. B. Hamilton.

A CONNECTICUT STATE SECTION

A meeting was held at Bridgeport on May 2, at which were present members from most of the prominent cities of the State of Connecticut. The object was to consider the advisability of forming a State Section, with branches at several centers. The existing New Haven Section was represented by Messrs. Henry B. Sargent, Chairman, Joseph W. Roe, and J. A. Norcross. It was agreed to formulate a plan whereby a Connecticut State Section will be organized, with headquarters probably at New Haven, where at least two meetings will be held annually, as at present, and in addition it is planned to hold each year at least one meeting at each of the following centers: Bridgeport, Hartford, Meriden and Waterbury. A committee was appointed to arrange the necessary details for putting the idea into effect, consisting of Messrs. Henry B. Sargent, Chairman, C. K. Decherd, H. E. Harris, S. F. Jeter and E. S. Sanderson.

A quorum of the Committee on Sections was present at the meeting, D. Robert Yarnall, Chairman, L. C. Marburg and Walter Rautenstrauch. Secretary Rice acted as chairman of the evening, and an address was made by Judge Edward K. Nicholson on ways in which engineers can coöperate in the mobilization of the resources, industrial and agricultural, of the United States.

The meeting approved a motion to petition the Council to take a referendum vote of the members of the Society to determine whether we should support national prohibition during the period of the War as a means toward greater industrial effectiveness and a saving in spoiled material.

BALTIMORE

April 12. At the meeting of the Section held at the Engineers' Club the following officers were elected for the ensuing year: Chairman, W. W. Varney; vice-chairman, A. B. Robertson; secretary, A. G. Christie; and treasurer, C. C. Thomas. William Chatard was elected a member of the Executive Committee.

Alten T. Miller, Vice-President of the Bartlett Hayward Co., of Baltimore, gave a most interesting address on Munitions and Preparedness, and the discussion of the subject which followed was of much interest and proved most instructive to all present.

A. KENNEDY,
Temporary Branch Secretary.

BUFFALO

April 18. A History of Aviation was the subject of the paper delivered before the Engineering Society of Buffalo by Charles M. Manly, Mem.Am.Soc.M.E. Mr. Manley, who has been actively engaged in aeronautics for many years, was associated with Professor Langley when the latter developed his ideas of the physics of the air and the art of flying. His paper treated particularly of the early development of aviation and included the present military problems being met in flying.

The following resolution was adopted at this meeting:

"Resolved, that the Engineering Society of Buffalo express its approval of the principle of universal and obligatory military training and service, and that we urge the Senators and Representatives in Congress of the State of New York, and particularly the Representatives of the Buffalo districts, to support in every way possible this principle, especially as it is embodied in the Administration measures looking to the raising of an army on this basis."

May 2. At the annual meeting John Younger, Mem.Am.Soc.M.E., resigned from the office of president, which he has held for three years, during which time the society has become known as one of the most energetic and useful engineering bodies. The election resulted in the choice of the following officers for the coming year: President, F. A. Lidbury, Mem.Am.Soc.M.E.; first vice-president, D. W. Sowers, Mem.Am.Soc.M.E.: secretary, F. B. Hubbard, Mem.Am.Soc.M.E.; treasurer, W. M. Dollar, Mem.Am.Soc.M.E.; directors, H. B. Alverson, Mem.Am.Soc.M.E., and F. E. Cardullo, Mem.Am.Soc.M.E.

LOUIS J. FOLEY,
Assistant to Secretary.

DETROIT

April 20. A number of the members and several ladies attended the dinner on this date, which was followed by an address by John W. Lieb, Mem.Am.Soc.M.E., on Leonardo da Vinci—Artist, Philosopher and Engineer. Mr. Lieb's address was most interesting, as it was based upon his researches during a residence of ten years in Italy, in the early days of electric railroading.

J. W. PARKER,
Section Secretary.

MERIDEN

May 3. An illustrated lecture on the Steam Turbine was given by J. Breslav, Mem.Am.Soc.M.E., before the Meriden members of the Society. This lecture proved of much interest and general discussion by those present followed.

R. S. BROTHERHOOD,
Secretary.

NEW YORK

May 8. Mr. Siegfried Rosenzweig, Mem.Am.Soc.M.E., addressed the meeting on The Development of the Poppet Valve Steam Engine with Special Reference to its Present Status in the United States.

Under the heading of thermal considerations, the author enumerated the advantages of high steam pressures and high superheats, and gave reasons why under such working conditions the poppet-valve engine is the most suitable type. He showed how

and why the application of high steam pressures and superheats and the development of the poppet-valve engine eliminate the multiple-cylinder arrangement, leading to compound engines and finally to single-cylinder engines, particularly of the uniflow type. The advantages and disadvantages of each type were defined and explained. Comparative steam consumptions of Corliss, poppet-valve and uniflow poppet-valve engines were given, and also the economies of small and medium-size turbines and uniflow engines were compared.

This part of the paper was followed by a consideration of structural features, in which the stationary engine, the locomobile, the marine engine, and the locomotive were described in a general way, and in a number of designs the development of these important types explained. The paper concluded with an explanation of a number of the different and most prominent types of valve gears and detail constructions, the latter with special reference to the best forms of cylinder designs. Both American and European types were shown.

The lecture was fully illustrated by lantern slides and drew forth considerable discussion.

A. D. Blake,
Section Secretary.

PHILADELPHIA

April 24. D. Robert Yarnall, Mem.Am.Soc.M.E., the speaker at this meeting, presented a paper on Recent Developments in V-Notch Weir Measurement.

The paper was fully illustrated with lantern slides and the speaker traced the early history of the V-notch weir, showing the various steps in its evolution up to the present time. Particular emphasis was put on the fact that the V-notch weir, irrespective of the particular make of the instrument, furnishes the most successful method of measuring liquids.

The results of the tests at the University of Pennsylvania, in which a Lea instrument was used, were given. Here the accuracy curve for various rates of flow was practically a straight line. The water used in the test was weighed by very accurate scales and the percentage of error during the entire test was about 0.6 per cent., while the guaranteed accuracy of most instruments of this type is about 1.5 per cent. A discussion followed in which J. W. LeDoux, Mem.Am.Soc.M.E.; T. C. McBride, Mem.Am.Soc.M.E., and L. F. Moody, Mem.Am.Soc.M.E., participated.

May 22. The closing meeting of the season was held on this date, and in order to continue the helpful spirit of coöperation now prevailing in Philadelphia, Mr. Willard Beahan, First Assistant Engineer, Lake Shore and Michigan Southern Railway, addressed this Section on Engineering of Men.

All the Members of the Engineers' Club of Philadelphia and all the engineering organizations affiliated with the club were invited to hear Mr. Beahan, and the response was general.

In order to further promote harmony and to tie the various organizations together more closely, a dinner was given to the chairmen of the several affiliated societies, the president of the Engineers' Club, and the president and secretary of The Franklin Institute.

W. R. Jones,
Secretary.

PROVIDENCE

May 2. The second annual banquet of the Providence Engineering Society, held in Elks Hall, surged with patriotic enthusiasm as the representatives of four of the allied countries addressed the audience.

Mayor Gainer, the first speaker of the evening, welcomed the distinguished guests and declared that the United States was in the war to stick until victory was assured.

Capt. M. de Jarny, a French military officer sent here after many months' service in the trenches to instruct the Harvard Training Camp, acted as the representative of Ambassador Jusserand. He said that the war is an engineers' war and that the United States, the greatest engineering country in the world, is sure to play a great part in it for that reason.

Capt. Nathan Horowitz, U.S.A., declared that the word "engineer" was a synonym for efficiency, and that efficiency must guide every action taken by the citizens here so that all the resources may be used to the best advantage. His brief talk closed with a reassurance that the coast defences of the country were sufficient as our harbors are amply protected by nets. He also said that we were not awake to the reality of war and that the sight of a submarine or Zeppelin might arouse us more fully to a realization of our duty.

M. S. Davidson, of Toronto, prefaced his talk with "Comrades-in-arms," which was greeted with applause. He said that the Allies had been confident of winning with or without the United States, but that he thought the war should be considerably shortened by the entrance of this country into the combat. The speaker said that the greatest good derived from the war was the new conception of life which all of the fighting countries are gaining.

Dr. Ira N. Hollis, Pres.Am.Soc.M.E., spoke on behalf of the United States. Dr. Hollis said: "Many young men have asked me in the last few weeks how they could do their share. Our country must provide a man for every place and we must have an agency of the Government to allot the men to the places where they can best serve. We serve best in this funeral procession on the way to the burial of the divine right of kings, when we fit into the place where we can do the most good."

Prof. Albert Van Hecke, of the University of Louvain, was Belgium's representative. He told of the sufferings that Belgium has undergone since the outbreak of the war and something of the atrocities, and followed with motion pictures of scenes in the refugee camps in Holland. These pictures gave views in the different workshops, homes, schools and playgrounds, and showed how the work has been systematized by Professor Van Hecke.

Albert Thornley,
Corresponding Secretary.

ST. LOUIS

April 11. H. R. Setz, Mem.Am.Soc.M.E., read a most interesting paper on Some Unusual Applications of the Diesel Engine, before the joint meeting of the Section and the Engineers' Club.

The paper dealt with the application of the Diesel engine to traction problems on railroads. The greatly varying relations between train speeds on level and rising or falling tracks, engine hp., point of cut-off and tractive effort were first explained by means of a typical dynamometer test chart from a steam locomotive.

Gasolene engines have for some time been used for traction service and, as far as the technical solution of the problem is concerned, have been an entire success. Mr. Setz explained why Diesel engines, owing to their greater flexibility, lend themselves even more readily to this class of work.

He then gave particulars of three methods by which the Diesel engine can be made use of for traction purposes, as follows:

Direct drive, in principle similar to the present practice with steam locomotives. Since at the slower speeds the Diesel engine would be unable to produce the necessary tractive effort, provisions must be made to increase artificially the mean effective pressure in the engine cylinder beyond that resulting from the regular cycle of operation. This is accomplished, while running, by the admission of extra charges of fuel oil together with high-pressure air, while for starting, the range cut-off of the starting valve must be extended to about 70 per cent of the piston stroke.

Mechanical drive, obtained by speed-change gears similar to present practice in automobile construction. For the purpose of smooth operation it is important that the engine hp. as well as the momentary tractive effort resulting from a change of speed be the same both before and after shifting the gear. Particular attention is to be paid to a suitable form of clutch. As modifications of the mechanical drive should be mentioned the various methods of hydraulic and compressed-air transmissions, which are primarily to increase the torque in starting and at slow speeds.

Electric drive, consisting of a regular Diesel-electric generating unit located independently on the car or locomotive without regard to the driving axles, which latter are driven by a suitable number of motors through gears. Here the torque may be varied either by varying the voltage or the speed of the engine.

Mr. Setz explained by means of diagrams and lantern slides the theoretical considerations underlying the different forms of Diesel engine propulsion.

A lively and extended discussion followed, showing that the subject was both interesting and timely.

L. A. Day,
Section Secretary.

STUDENT BRANCHES

Members of Student Branches are requested to notify the Secretary of any changes in dates as promptly as possible, in order to facilitate delivery of The Journal.

The Society has received from the Student Branches accounts of the measures taken by the student bodies regarding preparedness for national defense. That each university and college is "doing its bit" in this respect is shown by the summarized reports below.

Armour Institute of Technology. Entire student body meeting once a week for drill; military training compulsory. One hundred undergraduates to enlist in Navy. Plans in formation for instruction to be given in internal-combustion engineering for men training for service in United States Coast Defense Patrol.

Bucknell University. Student branch offered services to War Department, with request as to how to be of greatest service.

University of California. Cadet corps numbers 1263; 35 immediately available for commissions and 300 within the year. One of the universities designated by the War Department as training school for aviators; school to start shortly.

Case School of Applied Science. All students taking military drill each day. Work to be increased toward end of term. Application now in for Government to establish senior unit of the Officers' Reserve Corps in this institution. Two instructors received commissions in Officers' Reserve Corps.

University of Cincinnati. Military problems being introduced in all courses in civil, chemical, electrical, and mechanical engineering.

University of Colorado. Engineers corps of 50 men formed. Company of cavalry organized; to be increased to full squadron shortly.

Colorado State Agricultural College. Nearly half student body applying for membership in Officers' Reserve Corps; some have received commissions. Military instruction given daily to undergraduates.

Columbia University. Aerial Coast Patrol Unit No. 4 in formation. Six-week courses in military and naval subjects started, to include trench warfare, map reading, radio telegraphy, mining, trench signal service, infantry drill, military law, practical navigation, electric steering, turret control, gyroscopic compass, submarine signals, etc. Ambulance unit plans in formation. Signal corps in training. Agricultural volunteer system inaugurated, with credit given to students volunteering. Military census being taken.

Cornell University. Cadet corps numbers 2000; training in charge of regular United States officers; equipment up-to-date and complete; corps comprised of regiment of infantry, engineering division, machine gun division, signal corps, ambulance division, and military band; officers of corps are students holding commissions. Six hundred students enlisted in Government service; majority in mosquito fleet at Newport. Cornell ambulance unit for service in France enrolled and equipped and now in service; second unit to leave in a few weeks. Plans for new field battalion of signal corps in formation. Complete military census of undergraduate body taken. One of the universities designated by the War Department as training school for aviators; school to start shortly.

Georgia School of Technology. School offered to Government as military training center for officers. Aviation school in formation. Government expected to take advantage of offer shortly.

University of Illinois. Usual military training being pushed to the limit. Student aviation corps in formation, with many applications for membership. One of the universities designated by War Department as training school for aviators; school to start shortly.

Johns Hopkins University. Reserve Officers' Training Corps organized at beginning of collegiate year; battalion of 250 men drill under officer from War Department. Five men have commissions in the Reserve Corps and thirty have enlisted in the naval reserve and state militia. Credit for balance of year given to all enlisting.

University of Kansas. Courses in military science and engineering organized under direction of Dean of Engineering. Many undergraduates applying for admission to Officers' Reserve Corps and to the Quartermaster's Department. Credit for the balance of school year being given students enlisting or taking industrial positions in the service of the country.

Leland Stanford Junior University. Credit being given students entering intensive military training or active service. About 800 students now in training. Large number of advanced engineering students excused to take up industrial work in connection with federal contracts. Officers' Reserve Corps has many applications for admission. A few students taking up aviation. Two complete ambulance corps now in France.

Lehigh University. Class in military training held four times a week. Chemists have list of men classified for industrial positions.

University of Maine. Two years' military training required of all students; courses rearranged to permit of entire student body taking military training two hours daily. Courses in map making and reading, problems of intrenchment, use of high explosives, and signal corps work established and well attended. Many students enlisting in Coast Patrol. Cadet battalion of 532 men.

Massachusetts Institute of Technology. Trains all constructors for Navy. All seniors graduated in advance and now in service. Military department, existing for fifty years, now being enlarged. Engineering courses being reorganized on war basis to train men for technical departments of the army, engineering division, coast artillery, signal corps, and ordnance. Laboratories placed at disposal of Government. One of the universities designated by War Department as training school for aviators; school to start shortly. Industrial survey of alumni, started last year, now being completed.

University of Michigan. Seven companies of engineers organized; drilling twice a week. Special courses being given in military engineering, camp sanitation, transportation of supplies and munitions, high explosives, etc. Many students leaving to join various military and naval units.

University of Missouri. Special company of fifty cadets now in intensive training; eight immediately available for commissions, and thirty more within the year.

University of Minnesota. Military corps numbers 1250; 50 immediately available for commissions; 300 to attend officers' training camp this summer. Resolutions passed by students pledging themselves ready and willing for active service.

University of Nebraska. Cadet corps numbers 800 men; 46 immediately available for commissions and 100 within the year.

New York University. Red Cross ambulance company of 100 men formed; drill three hours a week under regular army officer. Four companies of Reserve Officers' Training Corps formed, seventy men to a company, receiving three hours' drill a week. Courses in ordnance and gunnery, electrical and steam engineering, signaling, and navigation on board battle ship *New Jersey* discontinued. Course in signaling to be given in university.

Ohio State University. About one thousand students leaving either for Officers' Reserve Corps, industrial positions, or agricultural pursuits; full credit being given these students. Sophomore regiment of cadets have open-order drill on Saturdays, besides regular drill periods. One of the universities designated by War Department as training school for aviators; school to start shortly.

University of Oklahoma. Compulsory military drill established throughout university. Engineering school forming signal corps for two upper classes. Sixty-four students to enter officers' training camp at Fort Logan H. Root, Arkansas. Intercollegiate Intelligence Bureau making complete investigation of alumni and undergraduates as to fitness for Government service.

Oregon Agricultural College. About fifty per cent of the seniors and twenty per cent of the junior engineering students qualified for Reserve Officers' Training camp at San Francisco. Full university credit being given these students. Many undergraduates leaving to take up work on farms.

Pennsylvania State College. Cadet corps numbers 1500; 300 men available for commissions and 300 more within the year. Courses being given in aeronautics, navigation, ordnance, and quartermaster work. Special instruction in ambulance and first-aid medical field service.

University of Pittsburgh. Survey of all students and alumni prepared and forwarded to National Intelligence Bureau. University wireless plant now at the service of the Government. Base hospital formed in school of medicine. Lectures given on camp sanitation. Regiment of six companies has 700 students enrolled; daily drill. Agricultural bureau of the university enlisting students for farm work. Full credit being given to those enlisting and to those taking up agricultural or industrial work.

Polytechnic Institute of Brooklyn. Training corps of 160 established; drills three hours a week at 13th Regiment armory. About twenty students in Naval Reserve and about 12 per cent. of the student body in active service.

Purdue University. Cadet corps numbers 1000; 300 to attend officers' training camp and will be available for commissions; 300 more within the year.

Rensselaer Polytechnic Institute. Course in military engineering established. Military instruction to be instituted immediately. Over one hundred undergraduates leaving for Officers' Reserve Corps, Naval Engineering Corps, regular army, or state militia.

Stevens Institute of Technology. All students being drilled five times a week. Commencement advanced to permit of students entering camps.

Syracuse University. Eight hundred students drilling twice a week; 150 graduate students to enter Officers' Reserve Corps. Ambulance corps being formed. Credit being given students enlisting or entering agricultural or industrial work.

Virginia Polytechnic Institute. Course of lectures by Red Cross representative attended by student body. Four hours of military drill daily. About one hundred students certified for admission to Fort Myer officers' training camp. Cadet corps a unit of Reserve Officers' Training Corps.

Washington University. Plans are now being made to form Reserve Officers' Training Corps, modeled after Yale's, to be under authority of War Department. About one hundred men already in national service and about one hundred more to be enrolled in reserve officers' training camps. Many students to go as ambulance drivers to France.

University of Washington. Cadet corps numbers 800; 100 available for commissions within the year; 85 to attend officers' training camp at San Francisco. Complete census of undergraduates and alumni taken.

University of Wisconsin. Courses offered in intensive military training with full credit allowed. Cadet corps numbers 1200; 140 available immediately for commissions and 600 within the year.

Worcester Polytechnic Institute. Military training of students under experienced drill officer. Number of seniors to take forthcoming examinations for commissions in regular army; such students excused from all regular institute work. Work of engineer officers outlined in address by Captain Williford, of Coast Artillery.

Yale University. About 1500 men engaged in military work; 300 immediately available for commissions and 600 within the year. Regular army officers in command of the men. Aerial coast patrol unit formed and in training. Naval training unit enrolled. Hospital unit organized and ready for service abroad. Signal corps unit in active training. Many students already in active service abroad. Laboratories offered to Government. Intercollegiate Intelligence Bureau work being forwarded.

Preparedness in its different phases is not confined to any group of universities or colleges, but throughout the country there is a general movement among college men to make themselves ready for the call.

Brown University. Military unit of 250 in training; 150 men organized for agricultural work. University equipped several ambulances for use in France. Many undergraduates to go to Plattsburg.

Colgate University. Military drill being instituted for all students under Plattsburg men. Full credit being given to all students enlisting or taking up agricultural or industrial work. Laboratories and other facilities of the university offered to Government. Special military courses being given.

Dartmouth College. Five hundred withdrawn to enter Naval Reserve, Reserve Officers' Training Corps, and Aviation Corps. Two complete ambulance units equipped and on the way to France. One thousand drilling daily. Military census being taken. Vacant land being intensively cultivated.

Delaware College. Ambulance corps organized and equipped. Military census of undergraduates and alumni taken. Many students leaving to enlist in active service.

Fordham University. Military training compulsory. Over 1000 students drilling daily, about 100 applying for admission to Plattsburg. Ambulance Corps No. 6 in formation.

George Washington University. First Company, Coast Artillery, District of Columbia Guard, formed in 1915, in active District service. Many students to enter Fort Myer Officers' Reserve camp. Military census taken.

Harvard University. Officers' Training Corps numbers 1200 men, under regular army command. Five French army officers assisting in training. Ambulance unit now in service in France.

University of Indiana. Training corps numbers 312, 70 per cent. of this number to be available within the year for commissions.

Massachusetts Agricultural College. Cadet corps numbers 126, 47 are available for commissions and have enrolled in the Government officers' training camps.

Michigan Agricultural College. Cadet corps numbers 875; 150 men are immediately available for commissions; 250 within the year.

New Hampshire College. Cadet corps numbers 380; 12 immediately available for commissions and 75 more within the year.

New Mexico School of Agriculture and Mechanic Arts. Intercollegiate Intelligence Bureau taking census of alumni and students. Agricultural school in full charge of agricultural resources of the state for greater crop returns. Practically all of engineering students applying for admission to Officers' Reserve Corps.

College of the City of New York. Complete equipment of chemistry building and services of faculty offered to Government. Resolutions adopted expressing students' willingness for national service. Ambulance unit plans in formation.

North Carolina College of Agriculture and Mechanic Arts. Cadet corps numbers 400; 60 available for commissions, 60 more within the year.

Norwich University. Cadet corps numbers 200. Ten seniors designated for regular army commissions and four as second lieutenants in the Marine Corps.

University of Notre Dame. Cadet battalion in training; 90 immediately available for commissions and at least one-fourth of the whole battalion within the year.

Pennsylvania College. Cadet corps numbers 314; 35 immediately available for commissions and 120 within the year. Many students to attend officers' training camps this summer.

University of Pennsylvania. Twenty-two hundred students drilling daily under regular United States officers. University Base Hospital No. 20 ready to sail for France. Over two hundred students enrolled in army of commissary for work on farms. Military census just completed.

Princeton University. Military drill established. Aviation school started, with more than two hundred applying for admission. About two hundred to enter officers' reserve training camps. Four ambulance units of twenty-five men each to sail for France the end of May for field service with the American Ambulance Corps. Full credit allowed those enlisting.

Rhode Island State College. Cadet corps numbers 252; 15 immediately available for commissions and 50 more within the year.

Rose Polytechnic Institute. Military training started. Plans being worked out in connection with National Defense Council and National Research Council. Laboratories well equipped for preparedness work.

Rutgers College. Reserve Officers' Training Corps numbers 300; 37 immediately available for commissions. Students being released for farm work. Plans in formation for students not in direct military service to enter munitions making.

Trinity College. Unit of Officers' Reserve Corps established. Half of undergraduate body drilling ten hours a week. Courses established in military science. Twenty-five men enrolled in Connecticut National Guard and others in ambulance and machine-gun divisions.

Tufts College. Military census taken of students and graduates. About fifty enrolled in Naval and Coast Defense Reserves. Division of ambulance field service now being organized. Twenty students accepted for Officers' Reserve Corps. Credit being given to those enlisting or taking up agricultural or industrial work.

Tulane University of Louisiana. All facilities of laboratories offered to Government. Questionnaire sent to 3300 alumni to determine number willing to enlist. Many graduates of Medical Department enlisted in service. Large number of engineering alumni in officers' training camps.

Union College. Two hundred and twenty-five students drilling four hours a week; non-commissioned officers' class for seventy-five. Courses of lectures, with field work, given on military engineering, code and flag signaling, and military topography. Military census taken.

University of Vermont. Student cadet corps of 250 men, 80 available for commissions within the year. University sent a complete infantry company and medical detachment to Mexican border last summer.

Williams College. Training corps consisting of 120 men, 200 available for Federal service within the year, 20 seniors to go to Plattsburg.

ARMOUR INSTITUTE OF TECHNOLOGY

April [illegible]. Robert Randolph was the speaker at the joint meeting of all the engineering societies, speaking on the Potential Resources of the Drainage Canal in Time of War. After the lecture which was illustrated with lantern slides, Mr. Randolph answered many questions concerning military matters and his explanations were most enlightening.

May 7. A business meeting was held at which the following officers were elected: W. H. Bretting, president; K. A. Taylor, vice-president; V. A. Kerr, secretary; N. L. Marvin, treasurer. The newly elected officers gave short talks following their appointment.

Abe J. Plocinsky,
Branch Secretary.

BUCKNELL UNIVERSITY

May 7. C. C. Kepple gave an interesting and instructive talk on the Field and Future of the Low-Pressure Steam Turbine. The most important point in the discussion was the showing of the increased efficiency of a plant due to the installation of a low-pressure turbine. Prof. F. E. Burpee, Mem.Am.Soc.M.E., gave a short discussion on the same subject.

C. M. Kriner,
Branch Secretary.

UNIVERSITY OF COLORADO

April 26. Organization was the subject of an address before the Branch by Prof. John A. Hunter, Mem.Am.Soc.M.E. Later the annual election of officers took place, resulting as follows: President, H. T. Sears; vice-president, R. B. Burlingame; secretary, H. O. Croft. The election was followed by a big get-together

H. O. Croft,
Branch Secretary.

UNIVERSITY OF ILLINOIS

April 19. In competition for prizes offered the Junior and Sophomore classes by Pi Tau Sigma, Mr. Shonkwiler delivered a short talk on Ice Plants and Refrigeration, and was followed by Mr. Morse, who spoke on Speed-boats and Hydroplanes. Both talks were interesting and well illustrated with lantern slides.

H. C. Dieserud,
Branch Secretary.

University of Cincinnati Student Branch Am.Soc.M.E.

KANSAS STATE AGRICULTURAL COLLEGE

May 14. Engineers' week was celebrated by the students starting with open house and a band concert, moving pictures showing many manufacturing processes and engineering works.

At the regular Branch meeting Joseph Harrington, Mem.Am.Soc.M.E., gave an interesting talk on boiler settings and furnace combustion.

A parade was held with many interesting and attractive floats, one of which was a small gas tractor, built complete in the college shops and consisting of a 1½-hp. gas engine mounted on specially built trucks, which gave a small but powerful tractor. There were many novel features among the floats, such as one which carried the power plant which furnished power and light for the other floats, another with a small mill in operation, one showing an electrical "wash day" as compared with the old-style kitchen, and many others of equal interest. The closing event of the week was the annual engineers' ball.

William N. Caton,
Branch Secretary.

MASSACHUSETTS INSTITUTE OF TECHNOLOGY

May 3. The close of a very successful year was celebrated by the Annual Banquet, at which the principal speakers were Ira N. Hollis, Pres., Am.Soc.M.E., Rowland W. Boyden, and Prof. E. F. Miller, Mem.Am.Soc.M.E.

Professor Miller sounded a warning to the men going out from the Institute into the Government's service in the capacity of munition inspectors, as they are open to many temptations in the way of graft.

Mr. Boyden said that it was now time for us to consider facts sanely and with calm judgment, as we receive proofs every day of the stupendousness of the task confronting us. Those in high authority in the Army and Navy must now have broad vision and administrative and executive powers in order to make an impression on the enemy, and we can congratulate ourselves on the number of men we have who possess these powers. The so-called "captains of industry" are just the men of this type who will produce efficiency, and Mr. Boyden cited several examples of both young and older men who are proving their patriotic spirit and devotion to their work.

Dr. Hollis advised the men to read history to see what the

end of the war is destined to be. He considered the definition of civilization as given by Louis Pasteur the best—"That civilization in which the individual is permitted to develop himself to the maximum capacity for the benefit of mankind." As the blood was to many of us the symbol of the washing away of the sins of the world, now bloodshed may again be worthy to fulfill the command, "Love thy neighbor as thyself." The development of the engineer, Dr. Hollis said, has gone hand in hand with democracy, and there is a tendency of science to weld the nations together. The mechanical engineer has a peculiar right to claim that his share in this war is preëminent, and each individual should prepare himself for whatever he is best fitted.

Announcement was made of the result of the election of officers for the coming year, as follows: Chairman, A. Saunders, vice-chairman, A. L. Hamilton, treasurer, H. W. Fitch, secretary, S. H. Caldwell.

S. H. CALDWELL,
Branch Secretary.

OHIO STATE UNIVERSITY

April 25. Mr. Fikret, instructor in the mechanical-engineering department, gave a well-illustrated lecture on the construction and equipment of the Essex Power Station of the Public Service Electric Company of New Jersey, with which company he was formerly connected.

F. E. SYMSER,
Branch Secretary.

OREGON STATE AGRICULTURAL COLLEGE

April 19. A general business meeting was held and officers for next year nominated.

May 10. After the regular routine of business the following officers were elected for next year: President, A. O. Leech; vice-president, F. P. Myers; secretary, H. W. Fish; treasurer, H. B. Morris.

ARCHER O. LEECH,
Branch Secretary.

OKLAHOMA UNIVERSITY

May 8. E. W. Pembleton addressed a joint meeting of the electrical and mechanical branches on Gasolene Extraction from Gas, and was followed by Prof. L. W. W. Morrow, who spoke on illumination.

The latter paper was illustrated by lantern slides and discussed the mechanical operation of the eye, the limited number of light waves which can be seen, and the causes and results of eye strain. The methods of avoiding them by proper illumination were also explained.

TOM L. SOREY,
Branch Secretary.

POLYTECHNIC INSTITUTE OF BROOKLYN

May 5. Samuel P. Blakeman, Mem.Am.Soc.M.E., gave a most interesting talk on S.K.F. Ball Bearings.

Mr. Blakeman described in detail the manufacture and various uses of the ball bearings and illustrated his points with many interesting lantern slides.

The following officers were elected for the coming year: President, Frederick H. Bromm; vice-president, Charles L. Schweizer; treasurer, Joseph L. Kopf; secretary, Nathan N. Wolpert.

GEORGE CHERR,
Corresponding Secretary.

SYRACUSE UNIVERSITY

May 7. After a few general remarks addressed by the President to the new members of the Branch concerning its principles and aims, short talks were given by Messrs. M. P. Whitney, M. P. Ferguson, Smith, and Lanigan. W. I. Rodgers, Jr., followed with a report of the Joint Student Branch Conference in New York.

The officers for next year were elected as follows: President, Maurice P. Whitney; vice-president, Walter I. Rodgers, Jr.; secretary, T. Dean Howland; treasurer, Malcolm P. Ferguson.

T. DEAN HOWLAND,
Branch Secretary.

VIRGINIA POLYTECHNIC INSTITUTE

May 1. City Management was the subject of a most interesting and informing paper presented by R. S. Royer, City Manager of Fredericksburg, Va. This is a new field of work for engineers and the paper was received with much interest by the members of the branch.

G. F. MINOR,
Branch Secretary.

UNIVERSITY OF WISCONSIN

May 3. Prof. W. J. Mead of the Geology Department gave an interesting illustrated lecture on Landslides at this meeting.

JOHN M. WOOD
Branch Secretary.

EMPLOYMENT BULLETIN

THE SECRETARY considers it a special obligation and pleasant duty to make the office of the Society the medium for assisting members to secure positions, by putting them in touch with special opportunities for which their training and experience qualify them, and for helping anyone desiring engineering services. The Society acts only as a clearing house in these matters.

POSITIONS AVAILABLE

In forwarding applications, stamps should be enclosed for transmittal to advertisers; applications from non-members should be accompanied by a letter of reference or introduction from a member, such reference letter to be filed with the Society. Copy for notices must be in hand by the 15th of the month.

INSTRUCTORS for school of mechanical trades in Iowa. Salaries $1,000 to $1,200. Promotion dependent to large extent upon commercial work which can be turned out during year. Men wanted now are as follows:

(*a*) Energetic young man with some business ability to take charge of automobile department doing large repair business; must know subject thoroughly and be able to build up department educationally and commercially. Competent to teach automobile lines, including electric-cranking, lighting and ignition course, to organize material and work in such way that maximum number of students can be handled with minimum teaching force and expense.

(*b*) Man to handle foundry and machine shop and possibly forge. 676.

TECHNICAL ENGINEER, with experience in steam engineering, to act as assistant operating engineer in large industrial plant located near Chicago. State age, experience and salary expected. 938.

YOUNG TECHNICAL GRADUATE with one or two years' experience in steam engineering, for testing work; location New Jersey. State age, experience and salary expected. 939.

MASTER MECHANIC for steel mill; experienced in this line of work and able to handle 60 to 75 men. Age 28 to 40, and a hustler. Salary about $2400. Location Pennsylvania. 1000.

DRAFTSMEN AND DESIGNERS. Experienced men with knowledge of valves and fittings; good future with large concern. State experience in full, salary expected and references. 1002.

ESTIMATOR, general jobbing and manufacturing shop; man ex-

... standard work. State ... salary desired and when available. Location New Jersey. 1006.

GENERAL CORRESPONDENT to be located in New York office of concern doing business with South American countries. Must speak Spanish. Prefer South American or one who has resided in South America and is familiar with conditions and language from personal experience. Salary depends on man. 1007.

FARM TRACTOR MANUFACTURER, well established, wishes to get in touch with large manufacturing property whose foundries and machine shops are capable of manufacturing at least 10,000 tractors per year including internal combustion motors of 30 hp. 1016.

SUPERINTENDENT AND FOREMAN of power plant. Capable of taking complete charge of large smelter plant consisting of steam turbines, large blowing engines and rotary blowers, Diesel engines, waste heat and oil fired boilers, pumping plant, high and low tension electrical equipment, etc. Must be familiar with combustion and operating problems, and have organizing and executive ability. Salary about $2500. Location Arizona. 1025.

DRAFTSMEN on miscellaneous mine and smelter equipment. Practical men with ten to fifteen years' mechanical and structural experience in shops, industrial plants and contract work, to act as squad leaders. Salary $190 per month, transportation refunded; 44 working hours per week; living expenses about $35 a month. Duration of employment not less than 5 months. Single men preferred. Location Copper Cliff, Ont., Canada. 1028.

GENERAL SUPERINTENDENT for plant with over 1200 employees near New York. Highly developed technique involving wide field. Applicant must have keen sense of justice and obvious ability to be successful executive in democratic organization. Thorough appreciation of importance of making deductions from facts alone; technical training. Men chosen for the position will be given opportunity to learn technique and establish himself in the confidence and esteem of the personnel. He will probably not be given full responsibility within a year. Plant is part of very large organization and affords ample opportunity for advancement. 1030.

ADVERTISING MAN. Boston advertising agency. Must be technically trained with advertising experience, preferably as advertising manager, and capable of taking full charge of accounts in engineering field. 1032.

DRAFTSMAN to make measurements and drawings of machine tools. Work will require considerable time. Good promise for the future. Young man of technical education and some practical experience, especially in machine tool work. Location Buffalo, N. Y. 1033.

PRODUCTION MANAGER. Age 35 to 45; married man preferred. Clean-cut, aggressive, of generous build preferred, executive ability. Technical graduate preferred, not absolutely required. Must have had actual shop experience in all departments, such as machine shop, drawing-room, tool designing, die making, etc. Thorough knowledge of design and operation of tools for press work absolutely necessary and familiarity with modern efficiency methods, including time studies, costs, planning, etc. Experience in electrical work desirable. Location vicinity New York City. Salary $3000 to $4000 or more according to qualifications. 1034.

FACTORY MANAGER, experienced in rubber industry, familiar with compounding and the different compounds. Salary $3000 to $4000. Location New Jersey. 1036.

MEN experienced in mill-room and press-room work of rubber industry. Day mill-room foreman. 1037. Night mill-room foreman. 1038. Foreman for press department. 1039.

MECHANICAL ENGINEER of some experience wanted for manufacturers of vegetable oils—linseed, castor, cocoanut, etc., crushing plants producing the raw material and refineries; young man out of college for five or six years, and engaged in manuacturing plant work. Knowledge of chemistry desirable, preferably both organic and inorganic. Absolutely trustworthy. Salary about $1800. Location New York State. 1040.

MASTER MECHANIC in long established manufacturing concern located near New York to take entire charge of construction, maintenance and repair departments, consisting of approximately 350 men. Must have experience and ability in organization, direction and efficiency methods. Excellent opportunity. 1041.

STEAM BOILER DESIGNER, experienced in water tube work. Location Erie, Pa. 1042.

REPRESENTATIVE AND SALES ENGINEER, especially in sugar house, and mill supplies; man from 25 to 35 years of age for manufacturers agents, machinery and supplies. Would be required to spend about three months in Cuba. Knowledge of Spanish essential. 1043.

MECHANICAL ENGINEER for about six months' position having several years' experience in the efficient use of steam in industrial plants, to systematize, distribute, run tests and economize on steam used for power, cooking and evaporation in various departments of large chemical plant. Hours 7—5.30. Salary $175. Location Brooklyn, N. Y. 1044.

SEVERAL INSTRUCTORS in mechanical engineering are needed by one of the large state universities in middle West, men having specialized training and experience in machine design, gas power engineering, and general laboratory work. Give complete statement of training, experience, minimum salary expected, and recent photograph. 1045.

INSTRUCTOR IN DRAWING, in large university in middle West. Technical graduate, preferably with drafting room experience. 1046.

YOUNG ORGANIZING ENGINEERS, for intensive management work, general manager's office, in one of the large units of the rubber industry. Opportunity decidedly promising. State initial salary expected, age, experience, qualifications, etc. 1047.

OFFICE EXECUTIVE for steel mill near Pittsburgh, competent to run office and direct men. Salary $125 monthly. Apply by letter. 1048.

MACHINE DESIGNER for automatic machinery for large rubber concern in northern Ohio. Prefer man with experience on machine tools. Pleasant surroundings, permanent position, opportunity for advancement. State age, education, experience, present and expected salary. 1049.

RESIDENT ENGINEER to superintend installation of foundations, buildings, gas machinery and piping. State experience and salary. 1054.

COMPANY manufacturing well-known food products desires mechanical engineer to study and improve methods of manufacture. Should have practical factory experience and be able to handle men. Good opportunity for energetic man. Location Long Island City. 1058.

TECHNICAL GRADUATE approximately 30 to 38 years of age with experience of sufficient breadth to be posted on problems of manufacture in more than one line. Man steadied by experience, yet ambitious to push ahead and interested in the various problems of manufacture and construction. Location Massachusetts. 1059.

ASSISTANT in mechanical laboratory of technical school in Greater New York. Recent mechanical engineering graduate with one or more years of practical work since graduation. Single man about 25 years of age preferred. Position offers exceptional opportunity for advancement. State age, education, experience, present employment and references. Enclose photograph with application. Salary $1200. 1060.

DESIGNER and lay-out man. Technical graduate with at least four or five years' experience in designing preferably on tools and fixtures, labor-saving and semi-automatic machinery. Location Michigan. 1061.

YOUNG MECHANICAL ENGINEER in cement plant, capable of designing machinery layouts, following up same in field and working into position of assistant superintendent. Give age, references and salary expected. Location Kansas. 1062.

SUPERINTENDENT for shipyard. Man experienced in the construction of wooden boats and barges. Eastern location. 1064.

FOREMAN in tool room of large factory making steel stampings. Salary to start $2000 to $2500. Location central New York. 1070.

YOUNG ENGINEERS desiring positions in which they might gain experience and advancement according to merit, in drafting room, in development of new and useful ideas and the improvement of old ones pertaining to oil well drilling tools. Salary $125 per month to start. Advancement according to capacity. Location Texas. 1071.

DRAFTSMAN familiar with piping layout of steam power plants, also assistant to chief draftsman capable of designing industrial buildings. Location Connecticut. 1074.

ELECTRICAL TESTER wanted immediately by Chicago blower manufacturer; will work as draftsman 20 per cent of time. Permanent with opportunity for promotion to salesman, designer or foreman. Salary $15.00 for first twenty weeks. Experience unnecessary. Describe education and physical condition. 1075.

GENERAL SUPERINTENDENT of shop employing about 500 men. Age between 35 and 42; technical education in mechanical engineering. Some knowledge of electrical and power plant engineering. Experience in machine shop work, ranging from small fine interchangeable work, tool and jig design and manufacture, intricate machinery, to finish machining work weighing 30 tons calling for the use of 100" lathes and kindred machines. Well educated, of good presence, self-confident, self-reliant, and energetic. New York State. Apply by letter. 1076.

MEN AVAILABLE

Only members of the Society are listed in the published notices in this section. Copy for notices should be in hand by the 15th of the month, and the form of the notice should be such that the initial words indicate the classification. Notices are not repeated in consecutive issues.

TECHNICAL GRADUATE, E.E. and M.E., some power plant experience; for last six years engaged as instructor in mechanical engineering in two leading technical schools. Desires position which offers opportunity for advancement in power plant or research work. Will be free after June 15th. F-199.

INDUSTRIAL ENGINEER AND DRAFTSMAN. Single, age 29. Five years experience on modern industrial accounting, planning and scheduling production, stores, determining standard tasks, standardizing equipment; designing draftsman industrial plants, special machinery and transmission work. At present employed. Good reason for desiring change. Interview New York City. F-200.

SHOP EXECUTIVE. Practical superintendent and technical graduate. Desires to locate in New York State or New England. Salary $3,000. F-201.

ASSISTANT TO EXECUTIVE. Graduate mechanical engineer, with eight years experience and some business training, can plan and follow up productive operations, wishes to engage with a growing manufacturing concern. F-202.

CONSTRUCTION ENGINEER. Stevens graduate, age 28, wishes connection with industrial company in construction or maintenance work. Has had seven years experience with large construction company for which he is now acting as purchasing engineer. Familiar with costs, specifications, and commercial as well as technical and practical features of building construction. F-203.

HEATING AND VENTILATING ENGINEER. Technical graduate. Seven years experience in design, installation and writing specifications for heating and ventilating and power plant equipment for group of buildings, industrial and public. Age 29, married. Minimum salary $2,000 a year. At present employed. Location immaterial. F-204.

MECHANICAL ENGINEER. Age 25. Technical graduate; power plant consulting, teaching, and some shop experience. Desires position with manufacturing concern where there is opportunity for advancement. At present employed. F-205.

TECHNICAL GRADUATE. Three years practical experience in boiler, gas and power plant work. Available latter part of June. F-206.

WORKS MANAGER. Graduate M.I.T., age 39. Thoroughly experienced in the manufacture and design of electrical devices and fittings, special and automatic machinery, armored cable, flexible metallic tubing and conduits, electro-galvanizing, sherardizing, etc. Specialized in the manufacture of interchangeable parts, applied for fifty patents, and had experience in patent litigation. Thoroughly conversant with modern shop organization, efficiency methods, production and handling men. At liberty June 1st. F-207.

MECHANICAL ENGINEER. Fifteen years experience in combustion and maintenance engineering. Would like to connect with large concern who wishes to improve conditions. F-208.

PRODUCTION ENGINEER OR SUPERINTENDENT. Successful executive. Technical graduate: 20 years experience in positions from foreman to manager. Experienced in revising plant management and in the introduction of modern systems. F-209.

MECHANICAL AND ELECTRICAL ENGINEER. Experienced in railway management. Twenty-four years practical experience. Can give good service in office management and administrative service, and assistance in organizing, engineering, maintenance or construction work. Knowledge and experience with materials of construction. F-210.

MECHANICAL ENGINEER. Age 47. Thorough and wide experience of 25 years in design and manufacture of general machinery, steam shovels, tank work, boilers, etc., including departments of correspondence, estimating, drawing room and shop construction. Desires agency or representation in City of Cleveland for outside representative and responsible firm. F-211.

ASSISTANT SUPERINTENDENT OR ENGINEERING EXECUTIVE. American, age 34. Eight years general engineering experience covering complete design, construction and maintenance of public utility properties. Energetic and ambitious. Has reached limit of advancement with present employers. Desires to connect with industrial concern within 300 miles of Chicago. Available upon three weeks notice. F-212.

SUMMER POSITION wanted by Junior Member with practical and teaching experience in drafting room, shop and laboratories. F-213.

EXECUTIVE OR SALES ENGINEER. Technical graduate. Past 15 years responsible charge of engineering work, construction, operation and management, together with several years experience as sales engineer. Desires position more or less executive. Salary to be commensurate with position. F-214.

MECHANICAL ENGINEER. Age 27. Columbia graduate. Five years experience in design, construction, and inspection with prominent concerns. Desires position in executive capacity, or as assistant with good chance of advancement. Employed at present, but will consider any fair offer. F-215.

WORKS MANAGER OR CHIEF ENGINEER. Graduate Stevens Inst. of Tech. Especially experienced along mechanical and operating lines; charge of design and tests of cars for city railway company, and operation of large steel mill for number of years. Assistant superintendent and chief engineer with well known firm of power transmission machinists and engineers. Experienced in production work in several types of industries for firm of consulting engineers. Salary $3,000-$4,000 depending upon character of employment. F-216.

ASSISTANT TO SUPERINTENDENT OR WORKS MANAGER. Technical graduate, 27. Four years experience as graduate student apprentice, time study man, rate setter and foreman of methods, with large manufacturing company. Available July 1st. Salary $1,800-$2,000. F-217.

MAINTENANCE-MECHANICAL ENGINEER. Graduate M.E. Columbia University. Design, inspection, shop maintenance and power house experience. Employed at present. Salary $30. F-218.

YOUNG ENGINEER. Age 26. Five years general machine shop experience, tool designing, and production work, graduating in mechanical engineering this June. Desires to locate with reputable concern in Southeast in production, efficiency work, or metallurgy. F-219.

ENGINEER, with experience in testing, operating, erecting, and repairing power house and boiler house equipment. Also experienced in various shop work. Technical graduate in steam and electrical engineering. At present employed but desires position with concern where there is chance of advancement. Location preferred in Western states. F-220.

MECHANICAL ENGINEER. Experienced in steam power plants, water works, compressing engines, rope drives, screw and pan conveyors, elevators and crushing machinery, and general mill machinery. Desires position with industrial manufacturing plant, in capacity of superintendent or master mechanic. Competent organizer and capable of handling men. Salary to be commensurate to position offered. F-221.

SALES ENGINEER. Practical machinist, technical graduate, experienced in drafting room, plant operation and selling. Age 31, married. Now holding position requiring salesmanship and good engineering ability. Desires change and would be available in 30 days to one looking for aggressive, capable man of integrity to push a line with merit, preferably on salary and commission basis. Willing to entertain straight salary or straight commission. F-222.

EXECUTIVE, ASSISTANT TO EXECUTIVE OR GENERAL MANAGER. Over 15 years experience in positions covering chief executive, office and works manager, consulting, construction, and efficiency engineering. Recent work has been in connection with manufacture of munitions. At present employed. F-223.

STUDENT MEMBER. Bucknell University. Graduate '17 in mechanical engineering course. Two years shopwork experience. F-224.

MECHANICAL ENGINEER. American, age 31, married. University graduate. Six years experience designing medium and light machinery. At present employed. Best references. Desires permanent and responsible position as designer or in any capacity in which experience will be available. F-225.

[illegible] ENGINEER OR PROFESSOR [illegible] M.E. [illegible] teaching [illegible] [illegible] engine laboratory [illegible] during [illegible] practical experience [illegible] operating and [illegible] plan work and [illegible] At present employed. F-226.

[illegible] PLANT ENGINEER. Technical education [illegible] practical experience. Desires position as [illegible] construction and maintenance of factory buildings and [illegible] with growing manufacturing concern where opportunity for [illegible] Experience as designer of modern factory build[illegible] engineer on erection. At present employed with [illegible] Salary expected not less than $2000 [illegible]

WORKS MANAGER OR ASSISTANT TO EXECUTIVE. Mechanical [illegible] technical graduate. Fourteen years varied experi[illegible] construction and installation work, including ordnance design [illegible] apparatus, hydraulic machinery and structural steel. [illegible] fundamentals of steam and electrical engineering [illegible] practical with executive ability, not afraid of work or [illegible] Location preferably East or South. F-228.

STUDENT MEMBER graduating in June from the mechanical engineering course of well known university, desires position in any mechanical engineering line in New York, New Jersey or Connecticut. F-229.

PRODUCTION SUPERINTENDENT. Twenty years experience in manufacture of interchangeable parts and designing of tools and fixtures for rapid production. Experience in engine and automobile parts manufacturing. At present located with large factory in Middle West. F-230.

RAILWAY ENGINEER. Age 37. Technical education. Seventeen years experience as railway machinist, draftsman, chief draftsman and mechanical engineer. Desires position with railway company, supply house or industrial plant, with greater responsibility and opportunity. At present employed. Location immaterial. Salary $2,400. F-231.

FUEL TESTING ENGINEER. Desires position as combustion engineer for large user of coal. At present employed. Technical graduate, age 34. Seven and a half years experience in scientific testing of coal in industrial plants, for large coal company in Middle West. F-232.

SALES ENGINEER. Desires position as sales manager for coal-operating company. Graduate, experienced in scientific testing and selling of coal. At present employed. F-233.

WORKS MANAGER OR SUPERINTENDENT. American, age 45. Practical and technical. Thoroughly familiar with all branches of the manufacturing business from drawing board to sales, on steam, gasoline and oil engines—standard, marine and tractor—mining machinery, electric motors and generators A.C. and D.C. Vacuum machinery and since the war on 18 Pr. shrapnel 18 Pr. H.E. 6-in. and 8-in. Howitzer. Specialized on efficiency methods, piece, premium and bonus systems, using unskilled labor as specialty men on accurate interchangeable parts, building and power plant construction. At present employed. Best of references. F-234.

DRAFTSMAN, MECHANICAL. Age 24. Experienced in the design and erection of steam power plants, wishes permanent position with power company, with chance of advancement. Not less than $115 per month to start. At present employed. F-235.

MECHANICAL ENGINEER. Sixteen years varied experience in testing, design, foundry, chemistry, metallurgy, special devices. Special aptitude for investigation work. Desires permanent connection with reputable concern leading to technical executive position. F-236.

RESEARCH OR EXECUTIVE POSITION. Technical graduate. Eight years industrial plant experience, largely in chemical and steel industries. Demonstrated ability in work requiring originality, inventive ability and thorough understanding of technical principles. Effected important improvements factory and power plant designs and operations. Capable in handling of men and development of subordinates. Position should offer not less than $3,300 and opportunity. F-237.

EXPERT ENGINEER-SALESMAN. Graduate of leading technical school. Age 35. Desires connection as salesman or sales manager with [illegible] manufacturing pumping machinery, air compressors, or internal combustion engines. Fourteen years sales experience in this line. Thorough, capable and aggressive and can secure results. Best of references from past and present employers as to integrity, honesty and ability. Minimum salary considered $2,500 per annum. New York City or vicinity; available on reasonable notice. F-238.

SUPERINTENDENT. Age 36. Practical tool maker with 18 years experience in light and medium interchangeable manufacture and has held all positions up to and including superintendent. Desires change. F-239.

MANAGER, MECHANICAL AND MARINE ENGINEER; designer; college graduate, age 36, married, American citizen, speaks English, French, Italian, Spanish, some knowledge of German. Three years practical experience as marine engineer. Six years district manager of electric illuminating and manufacturing company. Six years experience in mechanical design of electrical machines with two leading American manufacturing concerns; expert calculating engineer. At present employed; five years in present position; open for engagement in U. S. or abroad. New York City preferred. F-240.

CEMENT MANUFACTURING DESIGNING ENGINEER. Cornell graduate with 20 years' experience designing, constructing and operating cement manufacturing plants both wet and dry processes; broad engineering and executive experience, wishes to make permanent connection where results count. F-241.

INDUSTRIAL ENGINEER, CHEMICAL PLANT EXPERIENCE. Nine years' experience in design, construction, operation and maintenance of industrial plant machinery and power plants. Wide experience in purchasing materials, handling all classes of labor and chemical plant design and maintenance. F-242.

WORKS MANAGER. Mechanical engineering graduate, 37 years of age, having had several years' successful experience as factory manager, desires to make change. Prefers New England location with growing concern in which an interest may be secured. F-243.

EXECUTIVE POSITION wanted by American, technical graduate. Twelve years' experience in steel plant and general engineering work. At present employed. Will arrange for New York interview. F-244.

The question may naturally be asked by the busy manufacturer: "Of what special economic value is all this careful adherence to system and detail in the training of boys for factory work, and what are the results obtained for the outlay of money required to maintain the training department and school, with the necessary corps of foremen, assistant foremen, instructors for the class rooms, clerk, stenographer, etc.?" The answer is this: Every manufacturer knows there are times when it is practically impossible to secure enough good journeymen to fill the departments of his factory with competent, skilled help. He is often compelled to take into his shops unskilled labor and break them in on one or two operations in order to turn out the required amount of product. Furthermore, there is a demand at all times in the larger establishments of the country for skilled labor, and this is where the economic value of training boys and young men is plainly demonstrable.

Out of a force of 400 to 500 apprentices, approximately 120 will graduate each year from the four-year course and hold certificates as journeymen. From 60 to 80 per cent. of this number will remain in the factory for a longer period than one year, and it is safe to assume that a reasonable percentage will remain for an indefinite period.

What is the result? There is a constant influx into the factory of young men possessing not only a knowledge of one of the several trades necessary, but trained in the various shop practices and routine of the factory in which they have been schooled. If these young men remain for a term of years, the employer gains the advantage of their services during the most active period of life, when the energies of mind and body are at their best. Furthermore, the chances of their continuing loyal and faithful to their employer's interest during their term of employment are, on the average, much greater than would be the case with newly engaged employees coming from other and distant localities and having little or no interest either in the city or the factory in which they are employed.—*American Machinist.*

ENGINEERING SURVEY

A Review of Engineering Progress and Attainment in Mechanical Engineering and Related Fields, Including a Digest of Current Technical Periodicals and a Selected List of Engineering Articles

Notes from the Engineering Colleges

Equipment of Laboratories—Investigations in Progress—Changes in Curricula

As a result of inquiries by The Journal, data have been secured from many of the schools and colleges which give courses of instruction in engineering, upon certain features of the professional work which they are undertaking. In particular, information was sought upon (1) characteristics of the laboratory equipment and the kinds of investigations in which the different institutions specialize; (2) tests or researches which have recently been under way or which are in prospect; (3) important changes in curriculum.

The replies have been summarized and the first installment of the information received is given below. In this connection, attention is called to the summary of what is being done by student bodies of the various colleges in military preparedness and service to the country, as recorded in the Student Sections' Department of this number of The Journal.

Johns Hopkins University

RESEARCH WORK

Separation of Tar from Coal Gas: It is hoped to develop a type of separator which will be simpler than those now in use and show an improvement over present methods of recovering the very valuable residues from the gas-manufacturing processes.

Cooling Water for Power-Plant Purposes: A new type of spray head or spray nozzle has been developed for finely dividing large quantities of warm water (Fig. 1). This can satisfactorily handle about 250 g.p.m. as compared with 40 or 50 g.p.m. in the case of other types. The capacity of the new nozzle and the fineness of division of the water are controllable from the side of the spray pond, and the nozzle can be flushed or freed from sediment or solid matter by operating the adjusting means. Probably the most effective known means for cooling water in large quantities is found in the forced-draft cooling tower, which is particularly effective because the cooling effect is controlled according to requirements. The newly developed spray head provides for complete control in a manner comparable to that of the forced-draft tower. The expense of installation and operation of a pond is very much smaller than that of a forced-draft tower. The investigation of the whole question of cooling water is still in progress.

Pumping Water with the Discharge from a Gas-Engine Cylinder: A device has been developed by means of which water can be elevated by attaching a spring-loaded relief valve to the cylinder of an internal-combustion engine and connecting it with the combustion chamber. Immediately after each explosion this valve discharges a certain portion of the hot gases through a nozzle similar to that of an ejector, and by the expansion of these hot gases through the nozzle, water is drawn from a suitable supply reservoir and is discharged through a pipe leading away from the relief valve. By this means large quantities of water have been elevated to a height of about 75 ft. Enough of the hot gas of explosion is left in the cylinder at each working stroke to cause the engine to continue to operate, in addition to pumping water. Upon closing the relief valve, the engine can carry the full load for which it is designed. This pump may have application in various regions where irrigation and reclaiming works are under way.

Concentration of Metal-Bearing Ores by Flotation: It is supposed that flotation is caused by the fact that certain oils will wet metal, while they will not wet or adhere to non-metal-bearing rock dust. Ordinarily compressed air is blown into the mixture of ore and water and oil. It has been found necessary in many cases to heat the air or the water, and further, to supply some carbon dioxide with the air. The discharge from a gas-engine cylinder is not only hot, but it contains something like 10 per cent of carbon dioxide, and the gas-engine discharge makes an excellent agitating medium, because of the high velocity with which it is discharged from the cylinder. These facts have led to the development of an agitator for use in the flotation process. The means are similar to those above described for pumping water. In both cases it is not the ordinary exhaust from the engine which is used, but high-pressure gases which would otherwise remain in the cylinder during the working stroke of the engine. Tests made show that a very satisfactory concentration is obtainable, and tentative arrangements have been made for trying the method at a mine.

Fig. 1 New Type of Spray Nozzle

Cleaning of Used Lubricating Oils: A new type of agitator for liquids has been developed, suitable for producing very minute subdivisions of liquids containing finely divided solids. It has been applied to clean used lubricating oils, particularly those of automobiles, trucks and the like. By the use of the agitator the finely divided carbon or other solid matter can be very easily and cheaply separated and the oil rendered suitable again for its original purpose.

Smoke-Stack Design: The smoke stack of the university power plant was designed with a view to investigating impor-

ant problems, and means were provided for taking accurate and extensive measurements of pressures, velocities, temperatures, etc., during the operation of the plant. Various problems are being investigated.

Measurement of the Air Required for Combustion in Furnaces: Means have been provided for measuring all of the air supplied to the Taylor stokers under two of the boilers in the power station. The determination of the size of blowers and the engines for operating them depends directly upon a knowledge of the amount of air required. This matter affects not only the operation of boiler furnaces, but also furnaces used in connection with the iron and steel industry in metallurgical processes. Some tests have already been concluded.

Losses in an Ammonia Refrigeration System: A very complete ammonia compression system for artificial refrigeration is available in the mechanical laboratory, and an investigation is under way for the determination of the losses of energy and the locations at which they take place. Means have been provided for accurately measuring the quantity of brine circulated in the refrigerating pipes; and this means of measurement is being utilized for another investigation, namely, the determination of the coefficient of discharge of a hydraulic weir when brine of varying temperatures and densities is passing the weir.

Cracking of Petroleum Vapors: The 125-hp. Diesel engine in the laboratory has been used for compressing petroleum vapors to a high pressure in a very brief period of time, with the object of producing separation of the vapors into such products as gasoline, etc. An investigation of this problem has been carried on, and it is expected that the results will be published at an early date.

Recovery of By-Products from the Distillation of Carbon in the Manufacture of Coke and Gas: In response to the demand among the industries for specific information for the production of artificial dyes, drugs, explosives, etc., a laboratory is being equipped for work in this important field. A fund of about $6,000 has been subscribed by the principal gas and coke companies of this country, and the equipment is now in process of erection. The instruction and operation of the plant will be conducted jointly by the Department of Mechanical Engineering and the Department of Chemistry.

Lehigh University

Equipment: Engineering testing laboratory, also physical, electrical, chemical, metallurgical and mining laboratories. The engineering laboratory has a boiler equipment of two water-tube boilers rated at about 100 hp. each. In the heat and light plant there are three 250 hp. Stirling boilers. The engine room of the laboratory contains a vertical triple-expansion engine of 75 hp., a 60 hp. compound two stage Ingersoll air compressor, a complete set of Westinghouse air-brake apparatus, two large condensers, a large belt dynamometer, a Cochrane feed-water heater of 250 hp. capacity. The engine room of the power house contains units of 50 and 100 kw. rating. Simple horizontal Ball engines are direct connected to General Electric alternating current generators.

The laboratory for testing materials contains a general testing section for iron and steel, a cement and concrete section, and a hydraulic section. An electric traveling crane of 10 ton capacity commands the entire central portion of the building in which the testing of large specimens is carried on. The general testing section is equipped with an 800,000 lb. Riehle vertical screw testing machine; an Olsen universal testing machine of 300,000-lb. capacity; smaller machines for ordinary tension, compression, transverse and torsion tests.

The mining laboratory consists of a gyratory crusher, rolls, screens, jigs, Huntington mill, classifiers, concentrators, gravity stamps, amalgamating plates, grinding pan, and cyanide plant, with the necessary apparatus. The laboratory for testing samples contains a small jaw crusher, a small gyratory crusher, rolls, sample grinder, a magnetic separator, and a small air compressor. A special department is equipped for flotation methods.

Experimental Work: Determination of the coefficient of expansion of silica brick; physical tests on properties of concrete columns.

Columbia University

Equipment: Only about 10 per cent of the research work in the mechanical-engineering department is done at the university, so that the laboratory equipment is used mainly for teaching.

Experimental Work: Tests for obtaining data alone are only casually undertaken and then only under special circumstances. The regular laboratory work for students is conducted on lines which are distinctly research in character. Ninety per cent of the research work is done in the field and consists not so much in research but in what is called development work—taking an invention, putting it into practical form to see whether it will work and modifying it until it does work. This work is all done for interested parties.

Development Work: The skill and experience of the research staff is reserved for development work in which there is a distinct commercial or scientific end clearly in sight before the start. People who do the work are the instructing staff and the employees of the firms interested in results. The work is paid for by the firms. Students are rarely used and when they are used, they are only permitted to make readings or make calculations on results. All kinds of researches are undertaken except on material of construction and on pure mechanism. The former are taken care of in the civil engineering and metallurgical and mechanical engineering departments of the university. The latter are also taken care of elsewhere. Some design work in pure mechanism in developing new machines is undertaken, however, this design going hand in hand with the shop work. The nature of the subject-matter of the researches undertaken is almost entirely thermal or chemical. The work is concentrated on processes of a thermal or chemical nature and equipment for properly carrying them out. The work ranges from small isolated problems to problems of large plant installations. Following is an outline of the organization as proposed:

Industrial Development Laboratories: These are to be created for the purpose of promoting the welfare of American manufacturing institutions through

a Furnishing equipment and the services of the best scientific thought in creating, perfecting and introducing improved methods of economic production of commodities and industrial services

b Training engineers in the science of industrial development to the establishment of more economic operating conditions in manufacture.

This service might be rendered through the following means:

a Transposition of new and important principles into industrial and operating units and their perfection into com-

mercial possibilities; for example, the discoveries made by the chemist in his laboratoray might be worked out on a manufacturing scale and plans and specifications may be made available to the manufacturer in developing new lines of industry or in perfecting old ones

b Analysis and development of old processes and their modification and improvement to meet modern economic requirements

c Improvement of physical equipment of plants and methods of business management thereof

d Plant appraisals and reports for financial, legal and ownership interests

e Public service; for example, through these laboratories may be had the best information on the engineering problems arising in municipal and state governments; municipal

Chemical Industries: Electrochemical laboratory, furnace laboratory, distillation laboratory, wet-reaction laboratory, destructive distillation laboratory

Mining Industries: Mining laboratory

Metallurgical Industries: Metallurgical-processes laboratory, ferrous and non-ferrous; metallurgical analysis laboratory

Electrical Industries: Electrical-development laboratories

Manufacturing and Transportation Industries: Aeronautical laboratory, marine laboratory, transportation building, machine-design building, hydraulic laboratories, refrigeration and compressed-air building, steam-engineering building, steam-boiler and furnace building, gas-power building, heat-transfer laboratory, mechanical-standard building and development shops

Administration: Administration building, power, heating and lighting plant.

engineers and engineering commissioners will be able to avail themselves of the best assistance in the erection and maintenance of public works, municipal light and gas properties, drainage, sewers, garbage disposal, street cleaning, paving and many other engineering activities of a municipality.

f Laboratory research on problems of allied interests; as, for example, ascertaining the cause of the failure of rails, the failure of concrete structures, the corrosion of steel structures, the rational conservation of natural resources, such as more economic methods of mining, more economic power generation, more economic methods of distributing commodities and such problems

g Service to the national government in connection with the Army and Navy equipment, etc.

The plant proposed for this purpose includes the following buildings:

The approximate cost is given at roughly two million dollars, to which must be added a like sum for the purchase of the necessary land. A proposed layout is given in Fig. 2.

Publications: Most of the material of the researches is not published because it is obtained for private parties. However, sometimes some of the results are in the form of principles of general interest which could properly be published, and the department promises in future to ask permission of its clients to publish material through the Society.

Curriculum: Theses are no longer required, and the time thus gained is devoted to direct work. This year is the last of the four-year courses of the old style. There is still one class left to be graduated this year. Next year is the beginning of the complete operation of the three-year engineering courses prece'ed by three years in college. This will put engineering in Columbia on the same basis as law and medicine. So far Columbia is the only institution in America which has established the three-year courses in engineering.

Massachusetts Institute of Technology

Equipment: The new mechanical laboratories cover an area of about 70,000 sq. ft. Before planning the laboratories a study was made of the equipments of other engineering schools both in this country and abroad. Leading steam, hydraulic, and refrigerating engineers were asked to criticise the preliminary plans and assistance of great value was obtained through this means. The equipment of the laboratories was selected with the following objects in view: first, to give a student practice in such experimental work as an engineer in the pursuit of his profession is called upon to perform; and second, to provide ample facilities for original investigation and research in engineering subjects. The laboratory is divided into six branches, material testing, steam and compressed air, hydraulics, power measurement, refrigeration and gas engine, and an expert in the particular line of experimental work is in charge of each branch.

Experimental Work: Design and construction of a machine for testing the crimp in tire fabric; tests of the relative wear of knit goods and design of machine for this purpose; economic investigation of central station conditions in several towns to determine whether or not the respective loads can be more economically operated from a common source; study of the effect of pressure on the temperautre at which spontaneous combustion of liquid fuel (gasoline, kerosene and some heavy oil) takes place; investigation of the heating of an automobile tire; study of the relative strength of rolled and cut screw threads in soft steel bolts; study of the theoretical possibilities of the different refrigerants and of various domestic refrigerating machines on the market, to determine those most desirable for domestic use; investigations of the effects of high-pressure steam on power plant operation; investigation of the strength of rivets due to duration of heating; determination of the respective lengths of copper, iron and brass pipes to give best economy in water heaters; investigation of the physical properties and performance of the Baush Universal joints; investigation concerning the effect of rest, after over-straining, on the elastic limit of steel; design of a hygrometer; investigation of the strength of phosphor bronze under varying thermal conditions; investigation of the strength of steel in the blue heat region; effect of reabsorbed moisture on fir and pine timber; study of wood preservatives; investigation of the effect of different sizes and aggregates in bituminous pavements; investigation of skew and plain arches of the same general dimensions; investigation of oyster shell concrete; effect on concrete of the time of mixing; study of the effect of various waterproofing compounds on concrete; effect of steam on concrete; strength of various types of rope; study of substances to prevent cement from setting; strength of magnesium alloys; strength of composite cables; strength of glue.

Leland Stanford Junior University

Equipment: The laboratory includes a good selection of apparatus for experimental work in fuel analysis, power plant work, automobile testing, friction and lubrication, refrigeration, hydraulics, hydraulic machinery, and aerodynamics. The laboratory for aeronautics has been developed along original lines in many respects. While it comprises the usual tunnel for testing models in an air-current, the main purpose at present is to carry out tests of various propellers. In this connection several novel instruments, permitting to carry out measurements of very high precision, have been developed. An interesting feature of some of these instruments is the application of the telephone receiver for location of the exact points in space or time which it is desired to determine for the purpose of measurement. The use of the telephone receiver in such connection, by no means usual in mechanical measurements, permits a considerable simplification of the measurement itself without sacrificing of the precision and to a certain extent eliminates the personal equation of the experimenter.

Experimental Work: Tests on oil heaters and coolers; investigation relating to thickness of oil film in journal; investigation on flow of oil in pipes in cooperation with the U. S. Bureau of Mines; investigation of air propellers for National Advisory Committee for Aeronautics; research on strength and durability of gear teeth under grant from Engineering Foundation.

Curriculum: The courses of instruction have been recast to fit in with the four-quarter system which the University has adopted, to become effective in the next academic year.

Case School of Applied Science

Experimental Work: During the past year the mechanical engineering department has made a special study of the fuel problem in Cleveland, and has been devoting its energy to the saving of coal in several of the small and moderate-sized independent power stations in and around Cleveland. The fuel problem has been a very acute one in Cleveland during the past year, as indeed it has been all over the country. Since the department is very well equipped to handle such problems, it can do the most good in devoting its energy in this direction.

Curriculum: Additions have been made as follows: a special course on the manufacture of high explosives and shrapnel, shells and time fuses; a course in field surveying adapted to military needs; modifications of the courses in physics and electrical engineering, directing the attention of the students to the application of electricity in warfare.

University of Washington (Seattle)

Equipment: Usual apparatus for student experiments on steam and gas engines, air compressors, and structure of materials; provision for research work on a 27-hp. gas producer, involving the use of mill refuse and bark; on a 2-ton refrigerating compressor plant; on lubricating oils; and on fuels. A dynamic balance for measuring wind pressures is being installed in the wind tunnel and it is expected to carry on an extensive series of tests on aerodynamical engineering problems.

The growth of ship building in this vicinity has been so great that the department expects to add a number of naval architecture subjects for the coming school year, and a new man to carry on some of this work and to handle the aerodynamic laboratory will be appointed during the coming summer.

Curriculum: Changes are proposed involving reduction in hours for mathematics, so as to have calculus for a year only, unifying the engineering courses for the first year at least, and the addition of a course involving engineering problems for the freshmen. This course is to be so arranged as to attempt a training in method and concentration, as well as to give insight into the nature of the work to be found in each of the engineering departments.

News of Other Societies

National Association of Cotton Manufacturers' Convention

THE convention met at the Copley Plaza Hotel in Boston, April 25 and 26, and was one of the most notable in the history of the organization as regarded attendance and interest of the program. It was also more diversified than usual, as it included in its numbers many representatives of other textile associations, from the South, West, and Canada.

The most important feature of the convention involved the report of the Committee on Enlarging the Scope of the Association. The general idea of broadening the activities of the association met the hearty approval of practically the whole membership. An essential feature of this broadening is the creation of a new class of membership—to be known as Sustaining Members, who shall contribute to the funds of the association on a payroll basis, no annual assessment being less than $50, nor more than $500. These sustaining members will enjoy the full privileges of active members and will also be entitled to such direct service as the National Council may be able to render.

The program differed materially in general character from those usual in former years. No printed papers were distributed, and, with the exception of the session on Wednesday afternoon, the topics under consideration were arranged in groups under the direction of different chairmen, who opened the discussion of subjects on which various members had come prepared to speak. This plan proved of greater interest and led to wider participation in the debate.

A number of technical papers were presented. John A. Stevens, Mem.Am.Soc.M.E., discussed the evolution of the steam turbine in the textile industry. He pointed out how from surprisingly small beginnings in 1883 the steam turbine has grown to such proportions that it has invaded practically every field formerly occupied by the steam engine, which is due to its many advantages as compared with the reciprocating engine, which advantages he carefully enumerated. It is an undisputed fact that the turbine in sizes over 1000 kw. has superseded the steam engine, and even in sizes 200 to 1000 kw. the advantage is still in favor of the turbine, particularly in sizes of over 500 kw. He covered the subjects of low-pressure turbines, mixed-pressure and bleeder types, and the use of reducing gear, and gave illustrated descriptions of representative mill installations. It is expected that a more complete abstract of the technical features of the paper will be given in an early issue of THE JOURNAL.

Representatives of the Federal and Canadian Bureaus of Forestry and of the Southern Pine Growers' Association gave several papers on mill roofs and decay of timbers.

Arthur N. Sheldon, Mem.Am.Soc.M.E., discussed the conductivity of mill roofs and methods for preventing condensation. He brought out that a certain thickness of roof is necessary for a given humidity, the thickness increasing as the humidity increases. The paper is based on experiments with concrete and plank roofs with various kinds of insulation. In the course of the paper the speaker pointed out that if the temperature of the underside of the roof coincides with the dewpoint for the particular humidity and temperature in use, there will be condensation. If the temperature of the underside of the roof is above the dewpoint, there will be no condensation on the underside of the roof, but condensation will take place somewhere in the interior of the plank, depending upon the heat gradient between the inside and outside temperatures of the roof plank. Hence, while it is easy to design a roof which would have no condensation on the underside, it is practically impossible (unless at considerable expense) to design a plank roof with no condensation on the upper surfaces, or somewhere in the interior of the plank. The speaker proceeded to give a comparison of a concrete roof properly insulated and a wood roof of proper thickness and insulation to prevent condensation. A diagram was shown indicating that a thickness of the roof plank of a little over 3 in. would be required, while a 4-in. concrete roof plus 1 in. of cork board would give approximately the same insulation. The prevention of condensation on the underside of the roof planks does not, however, eliminate the possibilities for decay, because there is always condensation between the roof covering and the roof boards during cold weather. It would therefore seem absolutely necessary to treat the wood timber to prevent decay.

Methods for identifying fungus growths were discussed by H. N. Lee, of the Forest Products Laboratory, McGill University, Montreal. The speaker outlined a course of investigation from which he hopes to be able to determine just what fungus is doing the damage to any wood, even if the fungus has not produced any characteristic fruiting body by which it would be immediately identified. He even hopes to be able to tell it from the effect on the wood itself when the fine threads of the fungus do not show. When this is done, any one having trouble from wood decay will have only to send to the laboratory a sample of the wood and the laboratory should be able to tell what fungus is at work; then as soon as this matter is worked out, it can be determined what change of humidity conditions is necessary to stop the development of the fungus, and with it the rotting of the wood.

At the banquet on Wednesday evening, April 25, Henry E. Crampton delivered an address on the Council of National Defense and the Cotton Industry. The speaker stated that there is a comprehensive plan being followed by the advisory commission of the Council, and a great deal more is being done than gets into the newspapers.

The papers of the Thursday session, April 26, were devoted to commercial matters and questions of health insurance, factory safety and sanitation.

A very complete and careful account of the proceedings of the convention will be found in the *Textile World Journal* for April 28, 1917, from which the facts of the present account were mainly taken.

National Electric Light Association Convention

INSTEAD of meeting at Atlantic City, as originally arranged, the National Electric Light Association changed its plans because of the war and held this year's convention in the Engineering Societies Building, New York, May 9 and 10. As characterized by the *Electrical World* of May 12, from which the main facts of the following account are taken, it was essentially a war convention. From the opening words of the president, Herbert A. Wagner, to the final adjournment, half a day earlier than anticipated, the serious responsibility resting upon the industry to make the best use of its facilities for the country was the dominant note of the business transacted.

The proceedings of this convention in their outward manifestations were vastly different from the usual sober and humdrum course of meetings of engineering bodies. Follow-

ing the appointment of the committee on the President's address a bugle was sounded, a squad of khaki-clad men marched in and the flag was raised, while the convention joined in the patriotic strains of "America."

The question uppermost in the minds of those in attendance, as to "How can we best serve?" was answered in the Public Policy Committee Report by saying that both as companies and as an industry the members of the N.E.L.A. can most effectively serve the nation by a continued maintenance of reliable service on the part of the public-service utilities, by conserving the health and safety of the public, and also by furnishing information and assistance to the Government through its organizations and technically trained men.

John W. Lieb, Mem.Am.Soc.M.E., who was elected war president of the association, spoke informally and presented interesting information on experiences in England, where the arguments of the companies supplying electricity secured temporary exemptions from call to the colors for their most important men, which gave them time to rebuild their organizations. He also called attention to the great difficulty of making the proper adjustments for the care of dependents of employees who go to the front without at the same time bankrupting the companies, and stated that it is still a moot question as to what may be exactly the best policy to be pursued.

The same problem was discussed by J. E. Aldred, who has large business interests in Montreal, Canada. While the original intention was to pay the men who went to the front the difference between their regular wage and what the Government gave them in the service, the plan was abandoned afterwards, to some extent, in favor of what is known as the Patriotic Fund. This, however, was not because the burden imposed on the companies by the former plan was excessive. In fact, the proposition not only stimulated enlistment, but also helped maintain the efficiency of the force left at home, so that in the case of the Montreal Light, Heat & Power Co. 30 per cent more business was done than in any previous year of its history. The change to what is known as the Patriotic Fund resulted from pressure from the agricultural sections.

L. A. Ferguson, Commonwealth Edison Co., Chicago, described a plan adopted by that company, but tentative to the extent that it is definite only until August 1. This is based on the theory that the company shall not pay anything to the man himself who goes to the front, but that it shall provide for the dependents he leaves at home.

Of the papers presented in the technical sections, the one of greatest interest to mechanical engineers is the report of the Prime Mover Committee, of which J. M. Graves, Mem. Am.Soc.M.E., is chairman. The report discusses turbines, condensers, station auxiliaries, stokers, refractory materials, coal handling and storage, weathering and spontaneous combustion of coal, etc. Feasibility and practicability of higher steam pressures, condenser cleaning, economical steam velocities and pressure drops, station instruments, analysis of power requirements of station auxiliaries, and treatment of boiler feedwater are also discussed, and comments made regarding Diesel engines, progress of waterpower development, operation and maintenance of hydroelectric stations, ice-handling methods and waterwheel testing.

The report states that there has been a great increase in the number of orders for large prime movers, the development of large condensers, boilers, stokers, and auxiliaries keeping pace with the development of the turbine. The largest turbine so far developed is rated at 70,000 kw., and the largest condenser on order has 100,000 sq. ft. of tube surface.

The tendency in regard to circulating pumps is in the direction of more water per pound of steam. With steam-turbine drive the general trend is toward high turbine speeds. Development work during the past year has been along the lines of adapting the underfeed stoker to high-ash Middle Western coal and to lignite, both of which are now being handled with entire satisfaction.

Owing to the increased rating of boilers the firebrick surfaces have been proportionately increased and higher temperatures have produced greater expansion and contraction in them, so there are more frequent failures both in arch and side walls. Various methods have been tried to strengthen the flat walls, but with little success. Buttresses built inside of the combustion chamber were burned off in a very short time. Sheet-iron linings were also tried, but were melted down as soon as the firebrick inside had been burned away or partly destroyed by slag.

Several pages of the report are devoted to an extensive discussion by J. A. Walls on the question of protection against different forms of ice, including frazil and anchor ice. It is pointed out that if the first formation of frazil ice is not quickly observed, the ice will accumulate so fast as to make a shutdown inevitable. One means of detecting the onset of frazil or ground ice is to immerse a chain in the flowing water of the forebay and examine it every half hour or oftener. Frazil or anchor ice cannot form until the temperature of the water drops to freezing; hence a graphic thermometer will, in many cases, serve as a warning against any danger which may threaten from this cause.

National Fire Protection Association

AT the annual meeting of the National Fire Protection Association, held at Washington, D. C., May 8-10, the main subject for discussion was the new and unusual fire hazards and danger to life and property created by the state of war, and which demand the utmost vigilance on the part of the state, municipalities, and private individuals. Definite recommendations were made which included the following: The adoption by municipalities of the standard building code of the Board of Fire Underwriters, and by the state, of minimum building requirements for its public institutions; the enactment in each state of a fire marshal law; inspection of buildings by city fire marshals; levying the cost of extinguishing preventable fires upon citizens disregarding fire-prevention orders; more extended use of the automatic sprinkler; study of the technical survey of cities made by the Board of Fire Underwriters in regard to fire risks and efficiency of fire fighting apparatus, and the education of the children and the public generally in careful habits regarding the use of fire.

Among the reports discussed were the following of particular interest to mechanical engineers:

Uses of Wood in Building Construction. Containing a new standard for mill construction, with data on the decay of wood and its prevention; and the strength of timber and how to calculate it.

Roof Openings (skylights) and Cornices.

Standards for Pipe and Pipe Fittings. Containing specifications and tabulated dimensions of sprinkler pipe fittings, including long-turn fittings.

Explosives and Combustibles. Dealing mainly with fuel oil, acetylene gas for welding and lighting, and gasoline, with sug-

gestions regarding the safety of acetylene apparatus and the safe use of motion-picture film.

Safety to Life. Dealing, first, with the number of occupants permissible in a building, basing the number on the stair capacity with a view to safe exit in case of fire; and second, classification of the occupants of buildings by inflammability of materials manufactured, stored or used. The first part of the report is comprised mainly of a tabulated form showing the capacity per unit of stair width, and the second part of an elaborate list indicating the materials manufactured or handled and the risk involved according to whether the property would be considered as of "low inflammability," "moderate inflammability," or "high inflammability."

Ammunition Manufacture and Safeguarding of Industrial Plants. This timely paper treats mainly of the situation existing in the manufacture of artillery ammunition and of small-arms ammunition.

A brief description is given of the types of shells and cartridges used and of the processes of manufacture. Suggestions are made for safety in manufacture, and the important feature of guarding ammunition plants which are subject to attack by agents of an enemy is considered, with definite recommendations calling for such provisions as the following: adequate fencing in of property; armed guards; adequate lighting of yard and fences; wiring fences with charged electric wire connected with tell-tale device which will give a signal in case of a short-circuit; bars or screens at windows; patrol organization, etc. The report goes into these matters very fully and in detail.

Fire-Resistance Construction. The important feature of this report is the discussion of what has been designated as "full," "partial" and "temporary" protection in order to indicate the fire-resistance qualities of various materials and types of construction.

Conferences have been held by representatives of various associations, including The American Society of Mechanical Engineers. The representatives of the Society were Ira H. Woolson, Chairman of the committee which prepared this report, and W. C. Mowry, appointed by John R. Freeman, Chairman of the Sub-Committee on Fire Protection of The American Society of Mechanical Engineers.

At these conferences it was decided that the terms "full," "partial" and "temporary" should be superseded by terms indicating time, such as 4-hr. protection, 2-hr. protection, 1-hr. protection, etc. A time-temperature curve, shown in the accompanying diagram, was adopted to indicate standards of fire resistance. A scientifically-determined time-temperature curve is regarded of so great importance that it has been proposed to make the subject one for discussion at the next annual meeting of The American Society of Mechanical Engineers.

Protection of Openings in Walls and Partitions. In this report a feature of importance relates to the control of automatically-closing fire doors in buildings. A definite recommendation is made for the use of apparatus the operation of which depends on the rate of temperature rise, to replace fixed-temperature devices such as now used. By such improved apparatus the door will be closed in case of rapid rise of temperature before a fire will have an opportunity to sweep through the doorway and endanger the contents of the adjoining room, as so often happens with the fixed temperature device, which does not operate until a certain predetermined temperature has been reached. The mechanism of the device which has been recommended is of considerable interest. When a rise of temperature occurs equal to 15 deg. or more within one minute, the air in an inclosed chamber expands a diaphragm plunger and sets into operation a series of releasing levers. Under ordinary conditions the air in the chamber is maintained at atmospheric pressure through the medium of a vent, which is calibrated to permit rise in temperature of

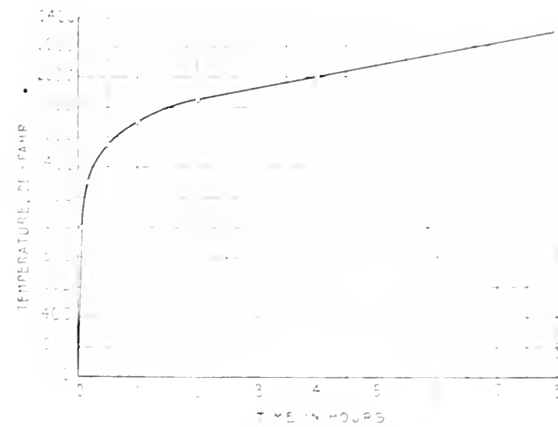

Fig. 3 Tentative Standard Time-Temperature Curve for Fire Tests of Building Construction

(1000 deg. at 5 min.; 1550 deg. at 30 min., etc.)

less than 15 deg. per minute without producing pressure enough to operate the diaphragm.

The secretary of the National Fire Protection Association is Franklin H. Wentworth, 87 Milk St., Boston.

American Chemical Society

The 54th meeting of the American Chemical Society was held in Kansas City, Mo., April 10 to 14.

Like all meetings at this critical period in the life of the nation, that of the chemists was held under the red star of war. The following resolution was unanimously passed by the assembled members: "Resolved, that we reaffirm the tender to the President of the United States of the services of the members of our Society in all the fields in which we are qualified to act. The progress of the war thus far principally teaches us that modern warfare makes extraordinary demands upon science, food supply and finance. For the protection and success of our men under arms we recommend the use, in their respective fields, of all trained chemists, physicists and medical men, including advanced students of these subjects, to this end, in collaboration with the United States Bureau of Mines, we are preparing a census of chemists. With no desire to avoid field service for men of training in the professions named, we urge that those of special ability be held to the work they can best perform. Thus we may avoid unnecessary loss from lack of control of the tools and requirements of war."

In the afternoon a public session on petroleum and natural gas was held, at which several papers were presented. Of particular interest to mechanical engineers are those of H. C. Allen and E. E. Lyder, on Variations in the Compositions of Gas of the Mid-Continent Field, and E. P. Fisher, on Some Experiences in the Use of Oxy-Acetylene Welding in Long Distance Natural Gas Transportation.

The temperature of a boiler tube is within 10 to 20 deg. cent. the same as that of the boiler water, and the temperature of the tube is affected very little by the temperature of the hot gases, but follows the temperature of the boiler water.

A Reference to the Spring Meeting of 1916

At the meeting of the House of Representatives on May 7 last, a quotation was taken from the New York *Times* of May 8. Representative John Q. Tilson of Connecticut, a Republican member of the Military Affairs Committee, discussed the manufacture of United States rifles, and disclosed the fact that only a very limited quantity of such rifles can be manufactured for the United States Government within a reasonable time because of the difficulty of procuring gages.

"Do you think that is good information to make public?" asked Representative Robbins of Pennsylvania.

"Everybody knows it except ourselves," replied Tilson. "All our enemies know it."

It is interesting to recall in this connection that the facts stated by Representative Tilson on May 7 were convincingly brought forward more than a year ago by members of The American Society of Mechanical Engineers at the Spring Meeting of 1916, New Orleans, in the discussion of Mr. Spencer Miller's paper on Organizing for Industrial Preparedness.

Among others, F. O. Hoagland stated that while the Government has at times placed small contracts for rifle-ammunition manufacture, no private manufacturer has ever made the 0.30 Springfield rifle, nor has he any special tools, fixtures, or gages necessary for making them. Quick service is not to be expected unless several of these concerns are placed in condition to meet the demand. Mr. Hoagland estimated that it would take about twelve months to prepare the special equipment of fixtures, tools and gages necessary for the production of, say, 100 military rifles per working day, and about half that time to prepare for 100,000 cartridges per day even when a factory has at the start a fair organization for similar work. The Government arsenals could be of great assistance in preparing the special equipment of fixtures, tools and gages, but a few leaders and workmen in each plant who are thoroughly familiar with the requirements are absolutely necessary in order to get quick and sure response.

In a joint discussion of the same paper, Frank O. Wells and Charles E. Smart pointed out the need for our machine shops to be equipped to manufacture munitions of war at short notice. While for over two years all the machine shops in the United States had been working for the Allies, yet new designs for jigs and fixtures were still upon the drawing boards and new gages and tools were being made in hundreds of shops all over the country. As a conservative estimate, they said, it would require 50 engineers, designers and draftsmen at least 50 weeks to prepare the drawings for the 17 sizes of shells now used by the United States Army, together with drawings for gages, fixtures and tools. To produce the latter would require probably 800 men well trained and in well-organized factories at least five years, calculating 300 working days per year. And this does not cover the question of aeroplanes, rifles, battleships, or a large number of other important parts of equipment which also must be provided for.

The manufacture of rifles formed the subject of a communication by Fred E. Rogers luminously covering the very points which Representative Robbins doubted the wisdom of making public at the present time. "The manufacture of rifles," wrote Mr. Rogers, "is a complete process, requiring special skill and experience, and with the exception of our Government arsenals, there was at the outbreak of the present war perhaps not one plant in the United States properly equipped and manned for manufacturing military arms. There are about 800 principal machine operations involved in making the parts of the simplest military arm, including the wood stock and hand guard. Many of these operations require special machinery, and practically all the parts must be in jigs or fixtures while machining. When we consider the fact that to provide equipment for an army of 1,000,000 from 2,000,000 to 3,000,000 rifles are required, the size of the task of equipping an army of 1,000,000 with shoulder guns alone becomes apparent. *What the condition of this country would be in a sudden emergency we can only guess. Judging from the experience of some of our ill-advised manufacturers who undertook to make shells, it would be of great confusion and enormous waste.*"

K. A. Juthe, in discussing the experience of American manufacturers in the production of rifles for foreign governments, stated that the gage problem was one of the greatest magnitude, as it was found that it would take at least 300 first-class gage makers to furnish the first working set, inspector's set, and the master set necessary for guns in quantities. And when 1000 complete rifles per day is figured on, it means that the working sets would be increased from one to ten, and the inspectors' sets from one to five, keeping the master set simply for reference. It was shown conclusively that among the total of practically 2500 to 3000 first-class gage makers in the country there was no adequate means of tackling several different propositions at the same time.

In regard to tool making, it was found that the jigs, fixtures and small tools required would take a small army of tool makers. It would take at least 1000 tool makers one year to furnish tools of this kind for the output of 1,000 rifles per day. Therefore, should our Government require, say, 500,000 or 1,000,000 rifles per year, our tool plants would be taxed to the utmost.

It appears, therefore, that what Representative Tilson stated in Congress did not disclose any military secrets, but as J. H. Brophy said at the meeting, "I am under the impression that it will take years of pounding away at the facts to enlighten the people on this great undertaking of Industrial Preparedness."

The way the situation has worked out, as announced by the General Munitions Board on May 15, is that the British Enfield rifle, chambered for regulation U. S. Army cartridges, will be used for our troops; and field guns of tried foreign types, but of American manufacture, will be introduced into the service. Manufacturing facilities for the Springfield rifle are not adequate to supply the number of rifles required for the force which the United States will raise and to replace the wastage of such a force. Fortunately the existing small-arms factories which have been turning out quantities of rifles for the British army are equipped to manufacture the Enfield rifle in more than sufficient number.

Engineering Committee of National Research Council

The first meeting of the Engineering Committee of the National Research Council was held on May 3 in the rooms of the National Advisory Committee for Aeronautics, Munsey Building, Washington, D. C., with Gano Dunn, Mem. Am.Soc.M.E., as Chairman. There were in attendance the following members of The American Society of Mechanical Engineers: Gano Dunn (Chairman), John A. Brashear, Wm. F. Durand, John R. Freeman, Hollis Godfrey, George E. Hale, F. H. Newell, S. W. Stratton, Ambrose Swasey, and Charles D. Young.

Mr. Dunn explained the necessity for coöperating with the engineering societies and for fixing the relations between the Engineering Committee of the National Research Council and the Committee on Science and Research of the Advisory Commission of the Council of National Defense, of which Dr. Hollis Godfrey is chairman. The scope of the work of the Engineering Committee as explained by the chairman is to be engineering incidental to research work and not original engineering work unconnected with research, although it was pointed out at the same time that the line of demarcation between these two fields is not very clear.

Dr. F. H. Newell then spoke of the work of the Institute for Government Research. This institute is financed privately and the work is conducted solely for the purpose of helping the Government to simplify its procedure and hence to economize, and its work has the active sympathy of the Council of National Defense and the National Research Council.

Dr. George E. Hale spoke generally of the relations of the National Research Council to other organizations engaged in national defense, in working out certain problems of great importance, the first of which was protection against torpedo attacks.

As regards the matter of the organization of the Engineering Committee the meeting adopted the suggestion of John R. Freeman, to the effect that a single head of the Engineering Committee resident in Washington should be appointed and confer with the other members of the committee and with the members of the National Research Council in Washington. Wm. F. Durand was appointed Washington head of the Engineering Committee—to be known as Vice-Chairman of the committee, with Mr. Dunn remaining as Chairman.

The matter of dealing with inventions next came up for discussion, i.e., whether inventions should be referred to the Naval Consulting Board or the Engineering Committee should undertake to pass upon them. After considerable discussion the matter was left to be determined by the Engineering Committee, but the consensus of opinion was that when it is a question of passing on an invention without relation to any other aspects of the matter, it should be referred to the Naval Consulting Board. In other cases the Engineering Committee should consider the matter.

It was generally agreed that as much publicity as possible should be given to the needs of the Government in the solution of its engineering problems by the engineering societies, with the understanding, however, that there are certain matters which cannot properly be made public.

At the conclusion of the meeting Dr. Godfrey spoke at length with regard to the relations of his Committee on Science and Research of the Council of National Defense to the National Research Council; but explicitly disclaimed any intention of doing research work or of passing upon research work in his committee, and stated that all research work, whether engineering or scientific, would be referred directly to the National Research Council.

New Equipment on the Lehigh Valley

THE general tendency in American railroad equipment to use heavier and bigger tractive units is well exemplified by the recent steps taken by the Lehigh Valley. This railroad succeeded in materially reducing its train-miles in freight service on several divisions by the use of powerful Pacific type and 2-10-2-type locomotives built by the Baldwin Locomotive Works.

By the use of the Pacific-type locomotives between Manchester, N. Y., and Coxton, Pa., a distance of 175 miles, two fast freight trains which were previously hauled by heavy 10-wheel locomotives having a tractive effort of 31,000 lb. have been consolidated. This achievement is all the more significant as the stretch is by no means an easy one. From Coxton to Summit, N. Y., about 120 miles, there is a steady upgrade with many curves, the gradient running as high as 0.4 per cent.

On the Wyoming Division, between Pittston and Athens, Pa., the Pacific-type locomotives are also used for heavy express passenger traffic. These locomotives are among the most powerful of their type, with a tractive effort of 48,700 lb., or more than twice as much as the tractive effort of the 10-wheel locomotives which they replace. While in many respects they resemble the latest design of the Lehigh Valley Mikado locomotives they differ from the greater part of the motive-power equipment on the Lehigh Valley in that they are designed for burning bituminous coal.

The 2-10-2-type locomotives are used in slow freight service between Manchester, N. Y., and Sayre, Pa., a distance of 88 miles, with 0.4 per cent grades. Each of these locomotives will haul 4000 tons and make the 88-mile run in 6½ hours, thus replacing two heavy consolidation locomotives. They burn a mixture of fine anthracite and soft coal.

The boilers for both of these types have a conical ring in the middle course by which the diameter is increased from 83¾ in. to 94⅞ in. The seam of the smokebox ring is welded along the top center line of the boiler. All the seams in the firebox, including those in the combustion chamber, are welded. The side and crown sheets are in one piece, being ⅜ in. thick; the door sheet is likewise ⅜ in. thick.

In both types of these locomotives the reciprocating parts are of special steel to reduce their weight. The piston heads are made of rolled steel of light section, 1 in. thick at the piston-rod hub and 11/16 in. thick at the outside of the web. Hunt-Spiller bull rings are held in place on the piston head by a retaining ring which is welded to the piston head. The packing rings are also of Hunt-Spiller metal. All extended piston rods are of Mikrome steel.

The crankpins, connecting rods, stop straps and extended piston rods are made of Mikrome steel. The piston rods are held in the piston head by a single nut provided with a nut lock made from a disk 5/16 in. thick in the body and ⅛ in. thick at the circumference. After the nut has been drawn up tight this disk is cut and bent over on to the faces of the nut. These nut locks are made of dead-soft steel and are used only once.

For the foregoing information credit is here given to *The Railway Mechanical Engineer*, May 19, 1917, pp. 231-234 (vol. 91, no. 5).

National Advisory Committee for Aeronautics

FROM a letter from the Committee dated April 27, 1917, is taken the following information supplementary to the article describing its constitution and activities in the May issue of THE JOURNAL (p. 454). This covers all information to date, of which some was not available at the time when the May issue went to press.

To facilitate the work of the Committee the following sub-committees have been established:

Aerial Mail Service. Brigadier General George O. Squier, U. S. A., Chairman.

Aero Torpedoes. Lieut. J. H. Towers, U. S. N., Chairman.

Aircraft Communications, Dr. Michael I. Pupin, Chairman.

Airplane Mapping Committee, Brigadier General George O. Squier, U. S. A., Chairman.

Bibliography of Aeronautics, Prof. Charles F. Marvin, Chairman.

Design, Construction and Navigation of Aircraft, Brigadier General George O. Squier, U. S. A., Chairman.

Governmental Relations, Dr. Charles D. Walcott, Chairman.

Nomenclature for Aeronautics, Dr. Joseph S. Ames, Chairman.

Patents, Dr. Charles D. Walcott, Chairman.

Physics of the Air, Prof. Charles F. Marvin, Chairman.

Power Plants, Dr. S. W. Stratton, Mem. Am.Soc.M.E., Chairman.

Relation of the Atmosphere to Aeronautics, Prof. Charles F. Marvin, Chairman.

Standardization and Investigation of Materials, Dr. S. W. Stratton, Mem. Am.Soc.M.E., Chairman.

Foreign Representatives, Dr. Charles D. Walcott, Chairman.

The Second Annual Report of the Committee has just been issued and copies may be had on application to the Committee. This publication contains reports on the following subjects:

General Specifications Covering Requirements of Aeronautic Instruments

Nomenclature for Aeronautics

Mufflers for Aeronautic Engines

Gasoline Carburetor Design

Experimental Researches on the Resistance of Air.

The Committee has also investigated the facilities available in various colleges, technical and engineering institutions, and among manufacturers and aeronautical societies, for carrying on special investigations.

At the present time the Committee is proceeding with the establishment of a field experimental station, near Hampton, Va., for the scientific study of aeronautical problems.

The Committee expects to have a testing laboratory, wind tunnel, and machine shop, and specifications for the necessary buildings are being prepared. The operations of the Committee will be in conjunction with the Army and Navy.

An investigation of air propellers, under the direction of the Chairman, Dr. Wm. F. Durand, Mem.Am.Soc.M.E., is being conducted at the Leland Stanford Jr. University, and a special wind tunnel has been installed there in connection with this work. It is expected that the results of this investigation will appear in the Third Annual Report of the Committee.

Work now being carried on at the Bureau of Standards comprises the testing of aeronautical materials, spark-plug investigations, and the study of carburetor design.

The patent situation in the aeronautical industry, which appeared to threaten its development, is in a fair way of being cleared up satisfactorily to all concerned, as a result of the interest taken in this matter by the Committeee.

The Committee will directly attack the more important problems of aeronautics as soon as its field experimental station is established.

If an examination of the ordinary hacksaw machine is made, it will be found that often the slides of the saw frame are narrow and do not have any convenient and durable method of maintaining alignment. The device for maintaining saw tension often is weak and cannot be locked to prevent loosening while the saw is in operation. These two features are important because unless the machine is well designed saw breakage will be excessive.

This Month's Abstracts

THE relation of horsepower to weight in an automobile and conditions affecting the output of same is discussed in an abstract of an article by A. Ludlow Clayden. Among other things, the writer points out the tempting ease with which fake power curves can be obtained, and touches in an interesting manner upon multi-valve engine design.

The relation between the chemical constitution and grain structure of bearing bronzes on one hand and their mechanical properties on the other is discussed in an article abstracted from the *Iron Age*. The writers claim that by scientific and skillful foundry methods a bronze containing lead may be produced without an impairment of its mechanical strength.

The tendency towards elimination of wastes is well illustrated in two articles on practically the same subject: one by Prof. J. W. Cobb, on The Utilization of Low-Grade Fuels, taken from an English publication; and the other on Coke Braize and Its Utilization, by W. A. Hamor, from *Coal Age*. These two articles show that economic burning of fuels, which until quite recently have been entirely wasted, may be considered an accomplished fact.

Wm. J. Leenhouts, from data secured in the Laboratory of the University of North Dakota, attempts to establish the basis for a scientific specification of gasoline. He rejects the gravity test, but considers volatility as the basic property of gasoline. At the same time he makes clear that with modern carburetors, products having a wide range of boiling points may often be economically burned. It is therefore suggested that if any specification be adopted by the Government, it should cover only the application of the name "gasoline" to a particular fuel, but should not restrict the sale of other fuels if marketed as "motor fuels" simply.

The application of regenerative principle to the design of gas furnaces is discussed in an article by W. C. Buell, Jr. Among other things, a graphic comparison of temperatures in the various parts of recuperative and non-recuperative types of gas-oven furnaces is given.

From the *Electrical World* is abstracted the description of the Montague City Station of the Turner's Falls Power and Electric Company, a large plant with a proposed output of 36,000 kw. Special attention is called to the enumeration of measuring and recording instruments used and the description of precautions taken against the spread of transformer fires.

In the section Measurements are given advance abstracts of three papers to be published by the Bureau of Standards, furnished to THE JOURNAL by courtesy of the Director of the Bureau.

The McClellon water-tube firebox is described and illustrated in the section Railroad Engineering, where will also be found an abstract of an investigation carried out at the University of Illinois on the resistance of passenger cars.

The deterioration of Curtis-Rateau turbine blading forms the subject of a paper presented by A. Fenwick to the South African Institution of Engineers and abstracted in the section Steam Engineering. An interesting part of this investigation is that referring to the use of aluminum bronze, which was found to be very satisfactory in the low-temperature stages, but entirely unsuited for the high-temperature stages. Attention is also called to the improved inlet nozzle, in which the cutting out of a portion of the vane eliminated troublesome breakage.

From a discussion of a paper on the Burning of Blast Furnace Gas Under Boilers, before the Engineers' Society of Western Pennsylvania, are abstracted data on the aspirating characteristics of various burners.

REVIEW OF ENGINEERING PERIODICALS

SUBJECTS OF THIS MONTH'S ABSTRACTS

Automobiles

Horsepower Facts and Fallacies, A. Ludlow Clayden

Discussion of the relation of horsepower to weight in an automobile, horsepower curves and conditions affecting output.

There is a limit to the power which can be used in an automobile, this being the amount of driving effort that can be exerted without causing the wheels to slip, which again is a function of the weight on the driving wheels. Actually, however, as the writer shows, the horsepower developed is rather below one-half of what the respective cars could transmit, providing the usually assumed coefficient of friction between the tire and road is correct.

The writer disagrees with the statement made that the steam engine is nearer the ideal for automobile use than the gas engine. While in the steam engine the power output is more constant than in the gas engine, what is particularly desirable in a car is constant tractive effort, and this is no more easily obtainable with steam than with gasoline.

As regards this latter, Fig. 1 shows curves of tractive effort per 1000 lb. of car weight plotted against speed for some cars of different types, fours, sixes, eights and twelves, of good makes. It is immediately noticeable that the best performance of any gives an effort under 16 lb. at the best speed compared with 25 lb., which is theoretically possible. The six or seven designers have apparently aimed at the best torque at low speed, leaving the high speed to take care of itself. The great difference in the shape of the curves is also very striking, especially as the curves from which these illustrations were made, had been submitted to the writer confidentially, and are, therefore, rather more accurate than the general run of "publicity" curves. None the less, there is some suspicion that the curves are not entirely reliable throughout their length.

In this connection the writer calls attention to the possibility of faking up power curves. An imaginary example of such a curve is shown in Fig. 2. The lower curve is probably obtained from the stock engine in normal condition, and then the upper curve obtained by tuning it up. Now, the normal condition curve is fairly accurate, and so is the tuned-up curve *above a certain speed.* But the upper curve cannot possibly coincide with the lower curve over the slow-speed range as shown in the illustration, and the departure from the truth is caused by drawing a good-looking straight line downward from the last observation (this is still more clearly brought out in the following paragraph).

Among other things the article discusses in an interesting manner the question of multi-valve engines. Fig. 3 gives a comparison of two curves made from the same engine with carburetors of similar design but different sizes. The better high-speed curve fairly coincides with the lower one at 800 r.p.m., and here the better curve really ends. With the larger carburetor, steady pulling at 700 r.p.m., with full throttle, was possible, but was not reliable. With a smaller instrument full-throttle operation down to 400 r.p.m. was certain, but at the

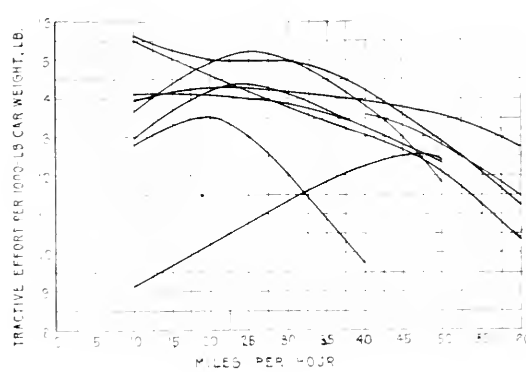

Fig. 1 Diagrams of Tractive Effort in Pounds per 1000 lb. of Car Weight Plotted Against Road Speeds from 10 to 60 m.p.h.

expense of loss of power at from 1500 r.p.m. up. Here one can see how easy it is to make a misleading curve. From having investigated the range from 800 to 2000 r.p.m. on the large carburetor, we should have a beautiful straight-line power curve, which looks just as though it would continue down to about 100 r.p.m.; but it does not.

The most interesting thing about these tests is, however, that even the largest carburetor used was far smaller than the "breathing capacity" of the engine. Hence, even with the largest carburetor, it would probably be found that, while the maximum power might be raised 20 per cent by using the full breathing capacity of the engine, it would not be possible to use full throttle below 1000 r.p.m., corresponding to about 25 m.p.h. with normal gearing. This brings the writer to the conclusion that increasing the valve size or lift, or using more than two valves per cylinder, would not help the power curve *throughout* the range of normal operation.

What the author thinks, however, is that the problem could

be [illegible] by [illegible] the power the same and [illegible] the weight of the car 10 per cent. This cannot be done at present, but the knowledge gained in light-engine build[illegible] from aviation work holds out a great promise

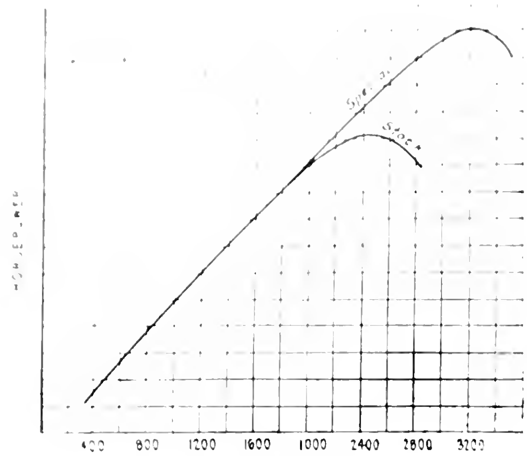

Fig. 2 An Imaginary Example of Fake Power-Curve Drawing

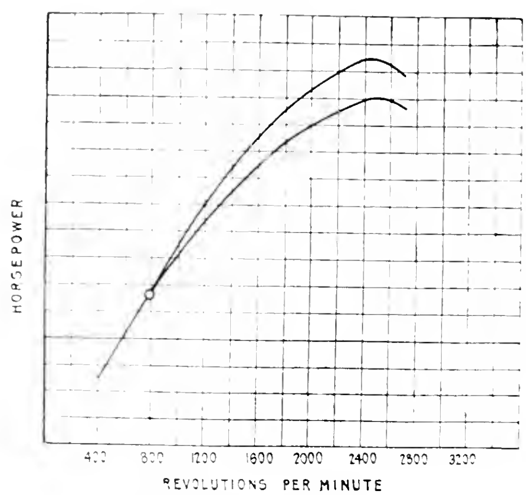

Fig. 3 Actual Curves Made from the Same Engine, but with Different-Sized Carburetors of the Same Make

for the future. (*The Automobile*, vol. 36, no. 17, April 26, 1917, pp. 820-824, 8 figs., *d*)

Statements that operation on kerosene as compared with gasoline gives a greater mileage per gallon if carburetion and compression are properly cared for, seem to be borne out by a recent A. A. A. test of a new system for using kerosene in which a distance of 25.5 miles per gallon was run on kerosene as against 23.0 m.p.g. of gasoline with a Ford car and stock carburetor.

This test was under sanction of the American Automobile Association and under the supervision of E. A. Hillman, representative of the A. A. A. contest board for this territory, Chicago. With the same setting of the carburetor at which the economy test was made, an acceleration from 10 to 15 m.p.h. was made in 15.6 sec. With that adjustment the car idled down to 10 m.p.h., but with a richer adjustment its running was good at 4 m.p.h. The car had been in service since last fall.

Engineering Materials

Bearing Bronzes and the Microscope, C. H. Bierbaum, Mem.Am.Soc.M.E., and Verne Skillman

Discussion of the relation between the chemical constitution and grain structure of bearing bronzes on one hand, and their mechanical strength in various respects on the other hand, and also discussion of the influence of lead on the properties of bearing bronzes.

In this case three bronzes were investigated. Two of these were found to be almost identical in chemical composition, but under tension test one was more than 50 per cent stronger than the other. This was explained when photomicrographs of these bronzes were taken. These photomicrographs are reproduced in Fig. 4, and show that apparently the lower tensile strength of bronze *A* was due to improper metallurgy and defective foundry practice in its production.

TABLE 1 CHEMICAL ANALYSIS AND MECHANICAL PROPERTIES OF THREE BEARING BRONZES

a Chemical Analysis

	Bronze *A* Per Cent	Bronze *B* Per Cent	Bronze *C* Per Cent
Copper	86.75	86.0	86.0
Tin	10.79	11.0	9.5
Lead	....	0.5	2.5
Zinc	2.40	2.5	2.0

b Mechanical Properties

	Bronze *A*	Bronze *B*	Bronze *C*
Elongation, per cent	1.5	8.0	6.0
Yield Point, lb per sq. in.	16,000	17,500	17,000
Tensile Strength, lb. per sq. in.	20,500	32,500	25,000

This would indicate the importance of making a microscopical examination in addition to chemical, physical and mechanical tests of metal alloys.

Another rather unexpected condition was found in two of these bronzes (*B* and *C*) whose principal difference in composition was that bronze *C* contained 2.5 per cent lead, while *B* contained none. The bearing value of lead in bronzes is well known, and it is also supposed that it weakens the metal. It has, therefore, always been a matter of compromise in the making of leaded bronzes as to how much strength should be sacrificed for a gain in bearing qualities. But if the strength of a bronze can be increased by scientific and skilful foundry methods, the bearing value of that bronze can be greatly increased by the presence of lead. This is claimed to have been done in the production of bronze *C*, where the presence of lead, while enhancing its bearing value, does not prevent it from having a higher strength than bronze *A* which contains no lead (cp. analysis in Table 1).

The two tables reproduced as *a* and *b*, Table 1, are of interest in that they give a basis for a comparison between the chemical composition and mechanical properties of the three bronzes above referred to. (*Iron Age*, vol. 90, no. 16, April 19, 1917, pp. 946 and 947, *d*)

Firing and Fuels

THE UTILIZATION OF LOW-GRADE FUELS. PROF. J. W. Cobb

Discussion of various methods of using very small fuel or dust. The difficulty of burning such fuel under a boiler is that a bed of it acts like a large sandlute, which acts, in its turn, as a gas sieve. The resistance of the numerous but minute channels through the fuel is so very high that, although the structure is quite porous, no reasonable pressure will drive any considerable quantity of air through it; while excessively raising the pressure results in the lute "blowing" in weak places.

In this connection, the writer describes the Bettington boiler, in which a blast of air carries the coal from a separator, through a fine sieve, to the bottom of a vertical water-tube boiler, and the mixed blast burns as a huge jet through a water-cooled nozzle vertically into the combustion chamber. The time which a particle, in passing through a boiler of this kind, can spend in the combustion chamber is remarkably small and therefore the combustion itself is usually somewhat incomplete.

Attempts have also been made to gasify coal in an air-dust stream, which only carries oxygen enough for the purpose of gasification, leaving the completion of combustion to be effected by a secondary air supply either in a furnace or in an internal-combustion engine. In other words, the dust system has been attempted with a measure of success for the manufacture of producer gas; e.g., by Marconnet. In this producer a fine fuel is fed into a hopper, from which it falls on a revolving plate driven by a friction wheel. From this plate a small scraper feeds a fine rain of coal by way of a sloping plate to a fan which carries the air thus charged with particles of coal to the producer. The speed of the fan determines that of the revolving plate and therefore the supply of coal varies automatically with that of the air. The air-dust stream enters tangentially at the bottom of the producer, while the gas leaves at the top.

Considerable quantities of dust coke have been effectively disposed of in Mond gas producers in England. Further experiments have also come to the attention of the writer in which very fine fuel was gasified with some measure of success by mixing with an equal proportion of breeze from a puddling furnace.

From this the writer passes to a brief consideration of the use of low-grade fuel in the form of briquets, and finally to a method of treating coal proposed by Bergius and consisting essentially in heating coal to fairly high temperatures (300 to 400 deg. cent.) in an atmosphere of hydrogen maintained under very high pressure. (*The Iron and Coal Trades Review*, vol. 94, no. 2,565, April 13, 1917, p. 419, [illegible])

COKE BRAIZE AND ITS UTILIZATION. W. A. Ha[illegible]

In by-product coke-oven practice it is customary to call braize, or breeze, that portion of coke which passes through a screen having $\frac{1}{2}$-in. square openings. The calorific power of dry braize approximates 12,500 B.t.u. per lb., so that it is actually a fairly high-grade fuel. It is, however, difficult to burn by ordinary means, and the use of forced draft is essential to its proper utilization.

Recently, however, combustion appliances have been developed for its utilization and several types of equipment originally designed for the combustion of anthracite culm have been found readily adaptable to the burning of coke braize.

In this connection, the writer describes in detail the Coxe traveling grate, which is now being successfully operated with coke braize in several plants (Fig. 5).

In this grate the fuel-supporting surface is made up of keys called grate tops, which are small castings approximately $\frac{3}{4}$ in. wide, 9 in. long, and 2 in. deep. The top surface is curved and the front end of each key matches the rear end of the next key.

The stoker shafts are of cold-rolled steel and each shaft carries keyed to it two cast-iron sprockets located just inside of the side frames. Cast-iron flanges project inward from the side frames. To these flanges are bolted sheet-steel plates, forming a floor between the side frames about 10 in. from the bottom thereof, with vertical air baffles at each end of the stoker. On top of the floor are built two air boxes, or [illegible] boxes, extending across the stoker between the side frames and communicating, on one end through rectangular openings, with one side frame with the air connections from the [illegible]-draft air duct.

It is recommended that the air for combustion be supplied at a static pressure of 2 to $2\frac{1}{2}$ in. of water. The fuel is fed to a hopper extending across the front end of the stoker above the grate from which it is deposited on the grate, the thickness of the fuel on the grate being regulated by the adjustable coal gate. There are three or four air compartments each extending crosswise in the furnace, and in each of

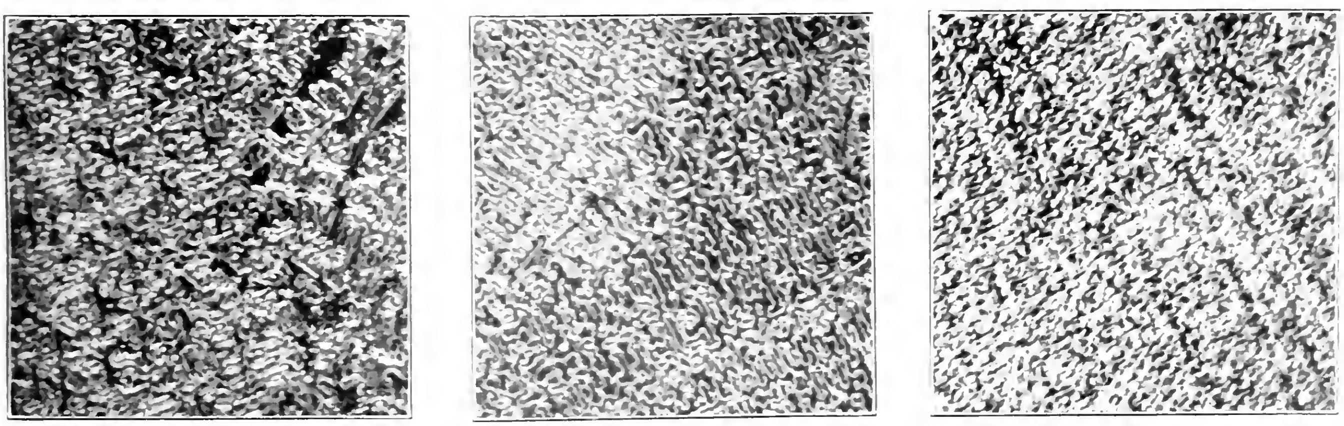

FIG. 4 PHOTOMICROGRAPHS OF BRONZES *A*, *B*, AND *C* (REDUCED ABOUT ONE-THIRD FROM THE ORIGINAL MAGNIFICATION OF 50 DIAMETERS) ETCHED WITH FERRIC CHLORIDE

that the air pressure may be independently regulated. It is thus possible to vary the rate of combustion over each air compartment as desired.

The three compartments may for convenience be called the ignition, combustion, and burning-out compartments; the function of these compartments being to enable the operation to vary the pressure under the grate in accordance with the thickness of fuel immediately above that section.

Under regular operating conditions in connection with a 500-hp. boiler, one of these stokers is stated to develop from 150 to 200 per cent of boiler rating with efficiencies ranging from 65 to 70 per cent.

The Parsons distributor has also been successfully used for burning coke braize. It consists of a steam-driven injector blower, which intermittently draws gas from the boiler furnace and projects it at high velocity against a small portion of the fuel which is simultaneously delivered into the path of the gas by a reciprocating pusher. A test (by C. J. Bacon, Mem.Am.Soc.M.E.) showed the efficiency and capacity of the

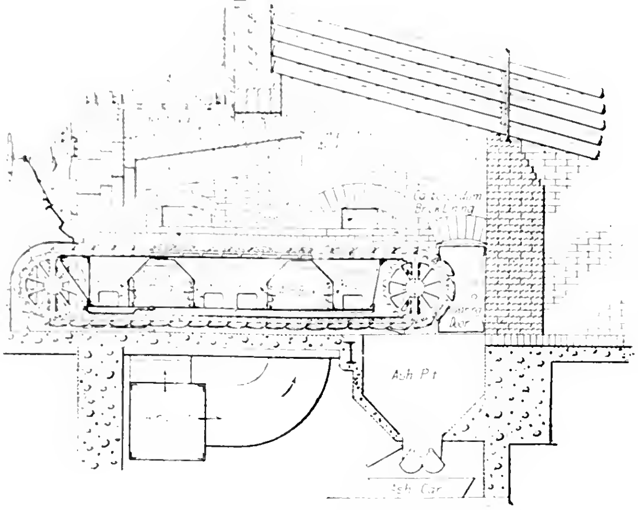

Fig. 5 Section of Cone Grate and Setting

distributor to be nearly the same with coke-dust as with coal. (*Coal Age*, vol. 11, no. 18, May 5, 1917, pp. 780-782, 2 figs., *d.*)

Gasoline Supply and Its Relation to Specifications, Wm. J. Leenhouts

Discussion of the supply of gasoline and its relation to consumption, the properties of modern gasolines and the bases of possible specifications.

Like every one else, the writer points out the probable inability of the present supplies of gasoline to hold out if the present rate and tendencies of consumption continue. He likewise points out that the great demand for gasoline has changed its quality very much. From year to year the residue in the gasoline has increased, which means that a larger portion of kerosene is being added continuously. The mixture of kerosene with gasoline does not, however, necessarily mean a poor motor fuel, as this depends on the amount and the portion of the kerosene range used in the mixing.

On the other hand, the claims made by many refiners for the superior power-producing qualities of their gasolines are largely without foundation. Automobile owners who have cars of suitable construction and necessary adjustments can get as good results out of cheap gasoline as out of expensive "high-test" product.

The problem of making a gasoline specification by legislation is not an easy one. The first question is what the specification shall be based on. The gravity test has been discarded by Director Manning of the Bureau of Mines. The investigations of the present writer show also that the gravity test may be entirely misleading. In the Petroleum Laboratory of the University of North Dakota there are two gasolines whose boiling range is nearly parallel and similar, but whose gravities are 49 and 55.5 deg. B. respectively. Further, the writer compares a gasoline of 49 deg. B. with the kerosene of the same gravity, and finds a difference of over 100 deg. in their initial boiling points, and a difference of 200 deg. in their end points. Because of this difference in the gravity for gasolines of a given volatility, gravity has been discarded as a criterion for rating a gasoline.

The basic property which determines a gasoline is volatility, or range of its boiling points. It is desirable to have a certain percentage of fairly-low-boiling constituents, so that engines may start more readily, but a large proportion would be undesirable because of loss through evaporation, and accidental ignition or explosion. A reasonable amount would probably be about 3.5 per cent at 158 deg. fahr. At the University Laboratory the average percentage of distillate at 158 deg. fahr. of all low-grade gasolines analyzed was 3.4 per cent for the year 1916 and 3.6 per cent for the year 1915. Again, a reasonably low end point is desirable in order to insure complete vaporization, but it makes an expensive gasoline. The average end point of low-grade gasoline is approximately 375 deg. fahr., with a residue of 37.5 per cent at 284 deg. fahr. The average end point for 1916 of all low-grade gasolines analyzed was 377 deg. fahr. and the percentage residue at 284 deg. fahr. was 37.6.

The grade of a gasoline is a variable factor when it comes to types of cars and their ages. Cars built three or four years ago were built for gasoline sold at that time, while a more modern car has a carburetor which can work efficiently with rather low-grade gasolines as put on the market to-day.

Hence, specifications, if made, must be broad enough so as not to exclude any type of gasoline from being sold.

The author suggests that perhaps specifications should cover only products sold under the name of *gasoline,* while all other products might be sold as *motor fuels.* Further, he suggests that any motor fuel might be placed on the market, but that it be labelled as to its 20 per cent and 90 per cent distillation temperatures, so that the purchaser would know the degree of volatility of the fuel he is buying.

If specifications are made, they should not be rigid and reduce the quantity of gasoline produced from a gallon of crude, nor should they in any way work against conservation of natural petroleum resources, and against the development of the petroleum industry.

In summarizing, the desirable properties of a gasoline are stated as follows:

1 Gasoline should not give a disagreeable odor before or on combustion. This is objectionable to users of automobiles and shows poor refining.

2 It should be free from matter not hydrocarbon, such as water, sediment, acid and sulphur. Acid and sulphur have a tendency to act upon the metal parts of an engine.

3 It should not contain excessive percentages of unsaturated

hydrocarbons because they have a greater tendency to carbonize.

4 It should not contain too large a percentage of volatile products because of loss through evaporation and danger of accidental ignition and explosion.

5 It should not contain a high percentage of heavy products which will not volatilize.

These are the requirements for a good gasoline. It still remains to fix the limits to these requirements. (*The Quarterly Journal of the University of North Dakota*, vol. 7, no. 3, April 1917, pages 251-260, 8 figs., *g*)

COMBUSTION IN THE FUEL BED OF HAND-FIRED FURNACES, Henry Kreisinger (Mem.Am.Soc.M.E.), F. K. Ovitz and C. E. Augustine

The main object of the investigation was to determine the conditions governing the process of combustion in the fuel bed in a hand-fired furnace. The results furnished data for correct design of coal-burning grates and furnaces and their efficient operation. They also cast light on the problem of clinker trouble as related to fusibility of ash, and indicated the possibility of a high rate of gasification of coal in gas producers.

The paper describes in detail the method of carrying out the tests and making various measurements involved, and presents the results in the form of tables and curves.

Among other things these tests indicate that with the 6-in. bed of Pittsburgh or anthracite coal the oxygen is all used up in combustion at a distance of 3 to 4½ in. above the grate. The CO_2 content reaches a maximum of about 15 per cent at a distance of 2 to 3 in. above the grate, and then decreases until, at the surface of the fuel bed, it is 7 to 10 per cent. At the surface of the fuel bed there is 20 to 32 per cent of combustible in the gases and practically no oxygen, but the percentage of the combustible in the gases increases rapidly beyond 3 in. above the grate.

With 12 in. beds of all three fuels tested and with the 6 in. bed of coke all of the oxygen disappears 4½ to 6 in. above the grate. But in all tests there was at the surface of the fuel bed a large percentage of combustible in the gas and no oxygen to burn it, showing that the fuel bed of any hand-fired furnace acts primarily as a gas producer. In many tests the gas at the surface of the fuel bed would be considered a fairly good grade of producer gas.

It was found that at the surface of the fuel bed and 1½ in. above it, the gases contained more oxygen, more CO_2 and less combustible than 1½ in. below the surface. This change in the composition of the gases was caused by air reaching the surface of the fuel bed from above, along the walls of the furnace, as shown in Fig. 6.

The effect of this downflow of air was much more marked with low rates of combustion than with high rates, because with a high rate the large volume of gases leaving the fuel bed more nearly filled the space above it and prevented the air from flowing down.

The fact that with coke the oxygen does not disappear as quickly as with the Pittsburgh and anthracite coal, is ascribed to the higher percentage of ash in coke and its uniform distribution through the combustible.

THE THREE COMBUSTION PROCESSES

The writers believe that combustion in the fuel bed consists mainly of three processes: namely, the oxidation of carbon to CO_2, the reduction of CO_2 to CO, and the distillation of volatile matter, this latter being of great importance with bituminous coal. The combustion is the result of contact of two streams, air flowing up through the grate and fuel which is fed from the top and gradually sinks toward the grate. At the bottom the air contains 21 per cent of oxygen and the fuel bed but little combustible; at the top of the fuel bed there is practically no oxygen and a high percentage of combustible.

The rate of oxidation of the lower part of the fuel bed depends almost entirely on the rate at which air flows through it. Next comes the reducing zone, in which the rate of reduction of CO_2 to CO depends on the temperature of the fuel bed and, up to a certain limit, on the length of time that the CO_2 is in contact with the hot carbon. The limit of reduction is the equilibrium between CO_2, CO and carbon at the temperature existing in the fuel bed, but at the high temperature which actually exists there the reduction of CO_2 to CO is a rapid process.

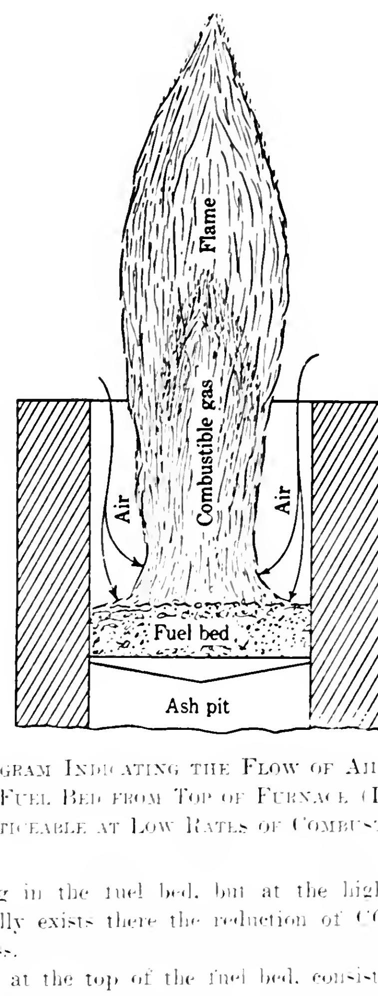

FIG. 6 DIAGRAM INDICATING THE FLOW OF AIR TO THE SURFACE OF FUEL BED FROM TOP OF FURNACE (DISTINCTLY NOTICEABLE AT LOW RATES OF COMBUSTION)

The layer at the top of the fuel bed, consisting mostly of fresh fuel, is the distillation zone. It overlaps the reduction area and extends about 2 in. below the surface of the fuel bed. There is, however, no sharp line of demarcation between the three zones, and particularly between the reduction and distillation zones. The rate of distillation depends on the rate of heating of the coal, which again depends on the temperature in the furnace, but with a given temperature the distillation is independent of the air supply, since when coal is heated the volatile matter distills off whether air is supplied or not.

Part of the combustible leaves the fuel bed in the form of soot, tar and cinders. The weight of soot and tar has been determined on eight tests with Pittsburgh coal, and comprises, roughly, about one-quarter of the combustible rising from the fuel bed. This quarter of the combustible is in a form which is difficult to burn in the combustion space, and if no provision

If the combustion is made a large part of it may go out of the chimney in the form of black smoke. It appears that smoke formed near the surface of the fuel bed and goes up to the chimney because the air supply is inadequate for its combustion. It is also possible that a large part of the volatile matter leaves the coal as tar, which immediately begins to break down into gaseous hydrocarbons and soot.

As to the temperatures in the different layers of the fuel bed, it appears that the temperature is highest between the oxidizing and the reducing zone, approximately at the point of maximum CO content in the gases. Further away from the grate in the reducing zone the temperature gradually drops, which is due to the reduction of CO_2, a heat-absorbing process.

Within wide limits the rate of feeding air has practically no effect on the composition of gases within the fuel bed, but affects directly the rate of combustion. In other words, if the rate of air forced through the fuel bed in a given time be doubled, the rate of combustion of the fuel is doubled, but the *weight of air forced through the fuel bed per pound of fuel burned or gasified is constant.*

For complete combustion air must be added over the fuel bed as the gases rising from the fuel bed contain a high percentage of combustible and no free oxygen, and this deficiency cannot be remedied by increasing the rate of air supply through the fuel bed.

Forced-draft apparatus cannot, however, supply enough air through the level fuel bed to insure complete combustion, and additional air must always be introduced over the fire in such a manner that it will mix with the combustible gases; otherwise a large percentage of them will escape unburned. The writers are careful, however, to emphasize that this does not make desirable admission of air through holes in fires and leaks in the furnace setting. The ideal way to supply additional air over the fuel bed is to introduce it as close to the fuel bed and in as large a number of small streams as possible. The nearer the air is introduced to the surface of the fuel bed, the more combustion space is utilized for mixing air with the combustible gases and for burning the mixture.

A thick fuel bed is undesirable because it increases the tendency of the coal to form troublesome clinker. Perhaps the only apparently defendable excuse for carrying a thick fuel bed is the fact that the chances of burning holes in the fuel bed are reduced. A skillful fireman avoids holes in the fuel bed by firing frequently and placing coal on the thin spots. A claim that fuel beds can not be kept in good condition if carried thin is a confession of neglect and lack of skill.

A fuel bed is understood to be only the layer of incandescent and freshly fired fuel, and does not include the layer of dead ashes and clinker on the grate.

The ash fuses in the upper layers of the fuel bed, and as it sinks it solidifies 2 to 4 in. from the grate. In most cases the fusion occurs in a reducing or partly reducing atmosphere, consequently in studying the fusibility of ash the determinations should be made in a partly reducing atmosphere.

As at the surface of the fuel bed the gases contain 20 to 32 per cent combustible gas and practically no free oxygen, to obtain complete combustion, additional air must be introduced over the fuel bed. This statement is true of all the fuels tested, including coke. As a general statement, about one-half of the 15 lb. of air used to burn 1 lb. of coal in a boiler furnace is supplied through the fuel bed; the other half must be supplied over the fuel bed. (*U. S. Bureau of Mines Technical Paper 137*, 1916, *etA*)

Furnaces

TESTS OF RECUPERATIVE GAS OVEN FURNACES, W. C. Buell, Jr

The regenerative-furnace principle has been applied to apparatus requiring high heat, such as open-hearth or glass furnaces, and has produced in addition to high flame temperature a material saving in fuel. To those operations in which close temperature limits are imperative, the regenerative principle cannot be applied directly, as the temperature of the heating chamber and the work of the regenerative furnace are highest just after the furnace is reversed. In fact, the pyrometer chart of the heating chamber of the regenerative furnaces resembles the edge of a saw, each sawtooth representing a reversal of the furnace.

The recuperative gas furnace described here has been designed primarily for the purpose of decreasing fuel costs. Of all the fuel used in a furnace from 25 per cent to frequently as much as 50 or 60 per cent is lost through the vent.

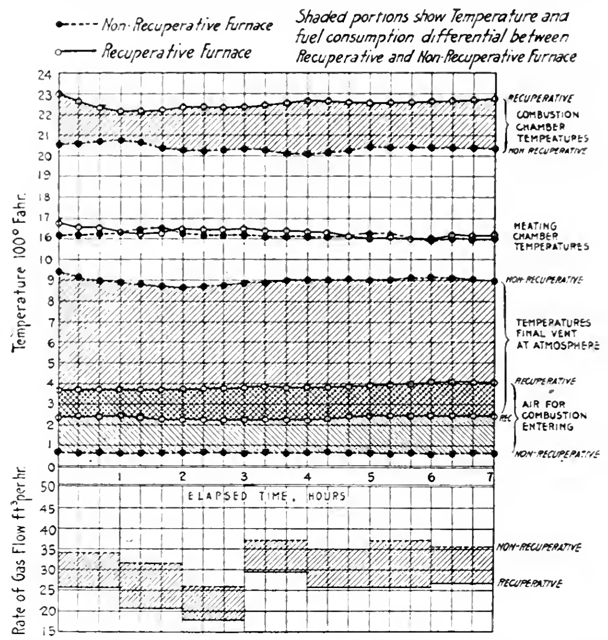

FIG. 7 GRAPHIC COMPARISON OF TEMPERATURES OF THE COMBUSTION AND HEATING CHAMBERS, FINAL VENT TO ATMOSPHERE AND ENTERING AIR, AND THE GAS FLOW FOR RECUPERATIVE AND NON-RECUPERATIVE TYPES OF GAS OVEN FURNACES

Economy to be secured by the utilization of the waste heat at this point is quite great, and in addition a further saving in fuel may be secured by the increase in flame temperature of the fuel through its preheating.

The chart reproduced in Fig. 7 is said to be typical of test runs with a Tate-Jones recuperative oven furnace and a non-recuperative one of the same size. A balance sheet from the same furnaces is presented in the original article with figures covering an average hour of operation after the furnaces had reached an equilibrium at 1600 deg. fahr.

From this balance sheet it can be said that 28,920 B.t.u. were required to maintain this furnace temperature with a recuperating attachment, and 36,400 B.t.u. were required when no recuperator was used. With the recuperator there was returned in the air only 1712 B.t.u., which represents a fraction less than 6 per cent of the total B.t.u. used, but in spite of the fact that only this amount was returned in the air, a *net* saving in fuel was secured of approximately

20 per cent. The additional 14 per cent saving was secured by the increase in flame temperature.

The same table shows to what extent the flame temperature operates towards economy. Combustion-chamber radiation losses were, for example, 17,122 B.t.u. in the regenerative furnace and 19,200 in the non-regenerative furnace. The final vent loss into the atmosphere was 3700 B.t.u. from the recuperative furnace, and 10,250 B.t.u. from the furnace without recuperator. The chart shows the increase in the combustion-chamber temperature due to the increase in the flame temperature.

The article discusses also the conditions at the outlet of the recuperator as an indication of the low temperature of the gases leaving the vent and the improvement in working conditions surrounding the furnace. (*Iron Age*, vol. 99, no. 18, May 3, 1917, pp. 1082-1083, *de*)

Hydroelectric Plant

Montague City Station of the Turner's Falls Power and Electric Company

The new 36,000-kw. generating station of the Turner's Falls Power and Electric Company at Montague City, Mass., is the largest hydroelectric station thus far built in New England. It supplies energy to 66,000-volt lines extending from the Greenfield District to Springfield, Mass., and generally covers the low-distribution networks in the Middle Connecticut River Valley.

At present only four of the six units for which the station is designed are installed. The wheels are of the vertical single-runner type, rated at 9700 hp. each. Each wheel drives a 7500-kva. General Electric 6600-volt three-phase revolving-field alternator at a normal speed of 97.3 r.p.m., the system frequency being 60 cycles.

The governors are connected with the shafts by flexible-gear drive, which is claimed to eliminate the troubles sometimes arising from belting. Each generating unit has a lignum-vitæ guide bearing lubricated by water received from the scroll case through a Terry cloth filter.

Since operation began the company has installed a water-cooling coil in each thrust bearing consisting of 145 ft. of 1¼-in. copper tubing per unit. Fifteen gallons of oil per minute are required to carry off the heat developed in each thrust bearing. The water for auxiliary cooling service can be taken either from the canal or from the municipal supply. The governor pumps are I. P. Morris horizontal centrifugal units rated at 325 gal. per min. each against a 525-ft. head, and are directly driven by 100-hp. induction motors. The sump tanks are installed in the pump pit and are cross-connected to a suction main from which the pump suctions are taken. The pumps discharge into a pressure main to which is connected a pair of accumulator tanks mounted on the operating-room floor, the governor-operating cylinders being fed from the pressure main, and discharging into a receiving main leading back to the sump tanks.

The guide and thrust bearings of the generating units are lubricated with ordinary machine oil supplied by gravity from a tank and filter located on a gallery, about 65 bbl. of oil being maintained in the system.

At each generating unit on the operating-room floor are located the governor with tachometer and gate-position indicator, the air-brake valve for controlling the rotor brakes, an engine-telegraph stand to connect with the switchboard gallery, a Peterson oil meter, one Schaeffer and Budenberg and three Peterson thermometers reading to 60 deg. cent. and connected with the oil piping, valves controlling the supply of oil and water to the generator bearings and governors, a Schaeffer and Budenberg recording thermometer on the thrust-bearing oil-discharge piping and a field-switch panel.

The following provisions have been made for isolating transformer fires. The transformers are located in a fireproof base on the east side of the operating room. All of the transformers are of the water-cooled type, with the circulating water furnished from the canal through the twin strainers and with an auxiliary town-water connection also available. The transformers are mounted on wheels, so that any unit can easily be removed by crane. Rolling firedoors, held open by fusible links, are provided for each transformer bay. Under the transformers are reinforced-concrete pits 18 in. deep which are connected with the river through traps for emergency oil discharge. The valve handle controlling this discharge is extended through the bay wall into the operating room to enable the oil to be discharged even when the firedoors are closed. Alarm devices are provided for indicating when the temperature of transformers exceeds 80 deg. cent., when the transformer cooling water is interrupted, when the governor-system water supply is too high or too low, when the bearing-oil supply is too high or too low, when the thrust bearings overheat and when the guide-bearing lubrication is interrupted.

Hourly readings are taken on the floor at each generating unit of the flow of oil to the thrust bearing, the oil temperature at the inlet and outlet of the thrust bearing, water temperature at the outlet of the guide-bearing gate opening and governor hydraulic pressure. The temperature of the transformers in each bank is also taken hourly. (*Electrical World*, vol. 69, no. 16, April 21, 1917, pp. 740-744, 8 figs. *d*)

Measurements

The Effusion Method of Determining Gas Density, Junius David Edwards

The effusion method of determining gas density, which is based upon the fact that the times required for the escape of equal volumes of two gases under the same pressure through the same small orifice are approximately proportional to the square roots of the densities of the gases, was investigated in order to determine the accuracy of the method and its sources of error. In coöperation with a number of men employing this method in the natural-gas industry, a series of experiments was made using their apparatus under field conditions. It was found that results in error by more than 10 per cent were not unusual.

The theory of the effusion process was studied in order to determine the influence of the numerous variables affecting the apparent specific gravity. The effect of differences in physical properties upon the relative rates of effusion of air and hydrogen, argon, methane and carbon dioxide at different pressures was determined. A more detailed treatment of the theory in the light of these results will be given in another paper. The facts observed in this study together with the observations made on the effect of the effusion pressure, the confining medium, and the shape and size of the orifice have been used in determining the most favorable conditions of operation for this method.

It is very important that the orifice be of the proper size and shape. Recommendations have been made as to the most suitable type and form of apparatus for use and specifications given to guide in the construction of the orifice.

It has been shown that the apparent specific gravity, as determined by this method, can be varied within rather wide limits by changing the conditions. However, by the observance of certain precautions in the construction and use of apparatus, it is possible to obtain results accurate to about 2 per cent. The greatest precision is obtained where the physical properties of the gas tested show the least difference from those of air. Some further increase in accuracy and particularly in reliability can be gained by standardizing the apparatus as recommended. (*Bureau of Standards*, advance abstract of Technologic Paper No. 94.)

The Relative Sensibility of the Average Eye to Light of Different Colors and Some Practical Applications to Radiation Problems, W. W. Coblentz and W. B. Emerson

In the present investigation the methods are practically the same as used by previous experimenters. In the visual measurements the spectral light was compared with a standard white light by means of a flicker photometer, and also an equality-of-brightness photometer. The source of white light was a standardized vacuum tungsten lamp. A cylindrical acetylene flame was used as a source of spectral light. The distribution of energy in the spectrum of the acetylene flame was determined with great care in view of the fact that the disagreement in previous work seemed to be due, in part, to uncertainties in radiometrically evaluating the light stimulus.

Visibility curves were obtained on 130 persons, of whom 7 were known to be color-blind. The visibility curve of the average eye, using 125 observers, is wider than previously observed.

As was to be expected, the visibility curves of no two persons appear to be exactly alike. When a visibility curve does not coincide with the average there is usually a marked departure from the average visibility in a given spectral region. This gives rise to (1) wide visibility curves with the maximum shifted toward the red, i.e., "red sensitive," (2) narrow curves with a sharp maximum in the green, and (3) curves with the maximum shifted toward the violet.

The data available indicate that 60 per cent of the cases examined fall into three quite evenly divided groups (i.e., 20 per cent roughly estimated in each group) which are either (1) red sensitive, (2) blue sensitive, or (3) average. Similarly, 30 per cent of the cases examined are quite evenly divided into three groups which fall below the average either (1) in the red, (2) in the blue, or (3) in both the red and the blue, thus giving rise to an apparently high sensibility in the green. One person in about 20 has a very wide visibility curve as compared with the average.

The point of maximum visibility is very different for different observers, and for the 125 persons the maximum is at 0.5576. The curve of average visibility, when corrected for selective transmission of the ocular media, including the yellow spot, is very symmetrical.

The complete paper gives a mathematical equation of the average visibility curve, and application of these data to physical photometry. Further applications are given in a separate paper.

Calculations are given showing that the eye responds to light having an intensity less than 1×10^{-16} watt.

This paper gives also data on diffused light and on the spectroscope used, and a screen is described which transmits radiations proportional to the average eye. (*Bureau of Standards*, advance abstract of Scientific Paper No. 303)

An Aneroid Calorimeter for Specific and Latent Heats, Nathan S. Osborne

The principle of the unstirred or "aneroid" type of calorimeter has been embodied in an instrument especially designed for determinations of the specific heat and latent heat of several substances in general use as refrigerating media.

Heat developed electrically in a coil located in the central axis of the cylindrical shell comprising the calorimeter is distributed by conduction to the calorimeter and contents whose initial and final temperatures when in thermal equilibrium are measured by a platinum-resistance thermometer.

Heat from other sources is excluded by enveloping the calorimeter with a metal jacket separated from it by the air space and keeping this jacket during measurements at the same temperature as the calorimeter surface, using multiple thermocouples to indicate this equality.

The calorimeter is adapted for use between —50 deg. and +50 deg. cent. and for pressures up to 70 atmospheres in experiments where the measured heat added is used either to change the temperature of the contents or to evaporate a portion of the contents withdrawn as superheated vapor; in the first case the specific heat and in the second the latent heat of vaporization being obtained when proper corrections are made. Such experiments are described in separate papers, this paper being devoted to the description of the instrument and its calibration.

Several features to which special attention has been given are:

1 Refinements to reduce errors in the evaluation of thermal leakage. These refinements include the following details:

a Location of the heater in the central axis of the calorimeter so that abrupt thermal irregularities produced by the heat developed therein may be subdued before affecting the surface

b Distribution of metal connections between calorimeter and jacket in such a way that the lead conduction is unaffected by inequalities in the surface temperature of the calorimeter

c Protection by means of superficial copper sheaths of calorimeter surface from abrupt variations in temperature such as may occur within during calorimetric measurements

d Method of indicating relative mean surface temperatures of calorimeter and jacket by means of multiple integrating thermocouples, which permits the evaluation of, and usually the annulment of, the thermal leakage.

2 Provision by means of a system of radial metal vanes for the distribution of heat throughout the contents.

3 Provision for insuring the dryness of vapor withdrawn by means of baffle-plate system.

4 Installation in the calorimeter of a strain-free type of platinum-resistance thermometer selected to give requisite accuracy.

5 Device for rapid cooling of the calorimeter consisting of a copper ring which can be moved within the jacket so as to thermally short-circuit the insulating air space and permit the escape of heat to the cooled jacket.

6 Thermo-regulated bath for keeping the temperature of the isothermal envelope or jacket always under control of the observer in order to avoid any unmeasured heat increments by thermal leakage.

Many other details are described which have a bearing on the convenience or accuracy in the use of the instrument.

The method of manipulation in making measurements of heat capacity is described, and the results given of an ex-

tended series of observations in the temperature range from —50 deg. to +50 deg. cent. to determine the heat capacity of the empty calorimeter. (*Bureau of Standards*, advance abstract of Scientific Paper No. 301)

Railroad Engineering

Mallet Articulated Locomotives for the Philadelphia & Reading Railway

Description of a heavy Mallet compound locomotive designed for pusher service over 3 per cent grades. These locomotives are of the 2-8-8-2 type and develop a tractive force of 98,400 lb. They are of special interest because of the restricted clearance limits imposed. The boiler center is placed 9 ft. 9 in. before the rail, and this apparently low elevation has increased the difficulty of working out some of the details of the design. The boiler is one of the largest Wooten boilers thus far built, with a diameter at the throat of 102 in. and a grate area of 108 sq. ft. It is designed for a pressure of 225 lb., but in service the safety valves are set at 210 lb. The equipment includes a Street stoker and power-operated firedoor and grate-shaker.

Owing to the restricted clearance limits it has been necessary to mount the safety valves in a specially designed casting which projects downward into a 26-in. circular opening in the boiler shell. This opening is placed just ahead of the combustion chamber. The rest of the equipment is not materially different from the usual practice on the Baldwin Mallet locomotives. (*Railway Review*, vol. 60, no. 18, May 5, 1917, pp. 620-622, 3 figs., *d*)

McClellon Water-Tube Firebox

The McClellon water-tube firebox has been in the process of development for a number of years and a few years ago one was built and applied to a Boston & Maine locomotive.

Another design has been recently made on two units installed on locomotives on the N. Y., N. H. & H. R. R.

It has been the aim of the designer to eliminate the use of staybolts and to divide the firebox into individual units which may better resist the expansion and contraction forces in service and may be removed with but little difficulty. The only staybolts used in the firebox are in the throat and the foundation or mud ring, which is a chamber $7\frac{1}{2}$ in. by 6 in., extending along the sides and back of the firebox. The sides and back head are made up of 6-in., $5\frac{3}{8}$-in. and 5-in. water tubes and the crown is made up of three drums as shown in Fig. 8. The tubes connect the drums with the foundation ring. The boiler is also provided with a combustion chamber $44\frac{1}{2}$ in. long, the sides of which are made up of tubes. These tubes follow the inside contour of the shell and extend from the outside drums to a circulating chamber which extends between the tube sheet and the throat. The chief method of construction of the firebox is by autogenous welding.

In the original article a photograph of the steam drums is reproduced. These drums were made from $1\frac{1}{4}$-in. plate planed down to $\frac{1}{2}$ in. in thickness. The front end of these drums is shaped to fit the barrel of the boiler and to make suitable connection with the tube sheet. The two side drums are butt-welded for $12\frac{1}{4}$ in. back from this end to facilitate shaping, and for the remainder of their length have a single riveted butt seam with $5\frac{1}{2}$ in. by 7-16 in. inside and outside welt straps.

The sides of the firebox are made up of fifteen 6-in. tubes equally spaced for over a distance of 91 in., which gives sufficient space between each tube to allow for expansion.

The combustion chamber is $44\frac{1}{2}$ in. long and contains from the front to the back two $2\frac{1}{2}$-in. tubes, eight 4-in. tubes and one 5-in. tube. These tubes extend between the side drums at the top and the circulating chamber at the bottom, being curved to the shape of the boiler shell. The circulating chamber consists of a $\frac{5}{8}$-in. flanged plate. There is a direct connection between the boiler barrel and the circulating chamber and also between it and the throat.

These fireboxes were applied to two Mikado locomotives weighing a little over 250,000 lb. The firebox heating surface of the ordinary boiler was 239 sq. ft., and of the McClellon boiler 308 sq. ft. Also, there was a little larger amount of heating surface in the fire tubes in the McClellon boiler and the total square feet of heating surface, including the super-

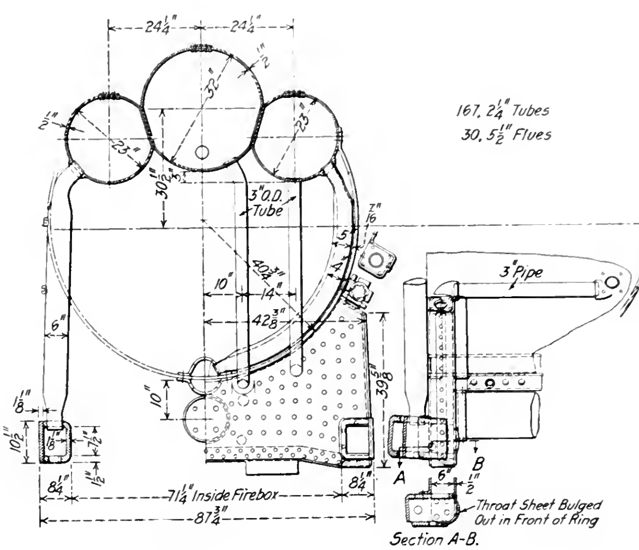

Fig. 8 Sections Showing General Details of the McClellon Firebox

heater flues, was 2827 sq. ft. for the ordinary boiler and 2937 sq. ft. for the McClellon boiler.

The locomotives with the McClellon boilers have not been in service long enough to determine the results. (*Railway Mechanical Engineer*, vol. 91, no. 5, May 1917, pp. 239-242, 6 figs., *d*.)

Resistance of Passenger Cars, D. C. Schmidt and H. H. Dunn

Data of an investigation of which the purpose was to establish the relation of resistance to speed for cars of various weights. The tests were made in regular through passenger service and it was found that the specific resistance is materially affected by the weight of the cars composing the train, and decreases as the average weight of the car increases.

The apparatus used with the dynamometer car produced continuous graphical records of the gross resistance of the train, the speed, time, brake-cylinder pressure, wind direction and wind velocity. All resistance values have been corrected for grade and for acceleration. The immediate purpose of the test was to define for each train the relation between net resistance and speed. All of these curves are brought together in Fig. 9.

The figure shows that at 20 m.p.h. the range of resistance [illegible] between [illegible] lb. per ton, and at 70 m.p.h. between 8.0 and 11.1 lb. per ton. This variation is chiefly due to the difference in the average weights of cars composing the different trains. Trains composed of relatively light cars have greater resistance than trains composed of heavy cars.

The relation between resistance and average car weight [illegible] graphically established in the following manner. [illegible] Fig. 9, at the point corresponding to 20 m.p.h., a perpendicular is erected. It will cut the curves in 18 points, each of which pertains to a particular train and defines for that train the average value of resistance at a speed of 20 m.p.h. If each of these resistance values are plotted with respect to

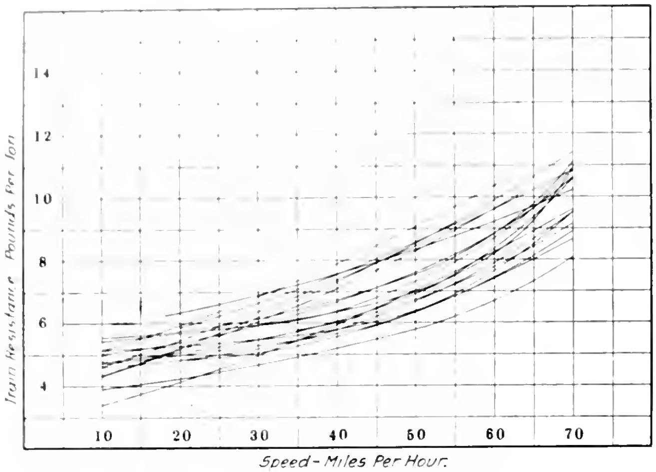

Fig. 9 Relation Between Resistance and Speed for the 18 Trains Tested

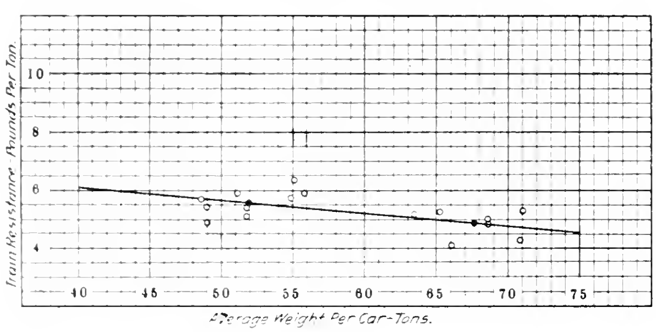

Fig. 10 Relation Between Resistance and Average Car Weight for the 18 Trains Tested at a Speed of 20 m.p.h.

the average car weight of the train to which it pertains, the diagram shown in Fig. 10 is obtained, which indicates that as the car weight increases the specific resistance decreases, the average weight of this decrease being shown by the straight line.

Six other straight lines have been determined defining this relation at 10, 30, 40, 50, 60 and 70 m.p.h.

As regards the numerical values appearing in the curves it should be borne in mind that they apply to trains running on level track at uniform speed in warm weather and under favorable conditions. Cold weather and high winds will both operate to increase the resistance above the amounts shown. (*American Railway Engineering Association*, Bulletin 194, abstracted through the *Railway Mechanical Engineer*, vol. 91, no. 5, May 1917, pp. 247-248, 5 figs., *e*.)

Steam Engineering

The Deterioration of Curtis-Rateau Turbine Blading, A. Fenwick

A paper devoted to the record and discussion of the behavior of certain materials used in turbine blading, based on a six years' experience in operating and maintaining the turbine plant of the Rand Power Company.

The turbines are of the combination Curtis-Rateau type. After passing through the first row of Curtis moving blades and a row of stationary blades fixed to a steel segment bolted to the turbine casing, the steam discharges into the casing in which the Curtis wheel revolves. The Curtis casing is a closed compartment separated from the Rateau portion by a cast-iron diaphragm. On the outer periphery of this diaphragm is a ring of guide blades forming nozzles which convert the steam pressure into velocity and give the steam the correct angle for impinging on the moving blades. The first ring of guide blades directs the steam from the Curtis casing on to the first Rateau wheel—termed in this paper the second-stage wheel.

Two main types of guide blading are in use, the first, termed a guide-blade ring, consists of inner and outer retaining rings cast round the blades. The guide ring is in two halves which butt together at the horizontal joint of the turbine casing.

The second type, the diaphragm, forms an integral part with the retaining rings, the complete diaphragm being cast in two halves. This type is called a guide-blade diaphragm.

The paper discusses the turbines by classes, starting with the 3000-kw. type. In this size in the Curtis stage and the first three low-pressure stages two materials have been tried, aluminum bronze and 5 per cent nickel steel. With the steel no particular trouble has been experienced from corrosion, and some sets have been running for six years.

The aluminum-bronze blades, on the other hand, proved quite unsuitable for this part of the turbine. The aluminum content disappears from the surface of the metal leaving a very brittle layer of copper. Where the section of metal is thin, as at the inlet and discharge edges of the blades, it breaks away like glass with light tapping. With continued use the outer layer cracks and flakes off, exposing the part underneath, which in turn flakes off until the blade is split up into several layers. Where a section of the blade is fairly heavy, as in the Curtis stage, the shape is gradually lost, but the body of the blade remains sound and seldom fails.

On the whole, the Curtis blades have a shorter life than the later stages, due apparently to the higher temperature in the Curtis casing. After leaving Stage 4 the deterioration takes a different form, erosion or pitting at the back or convex portion of the blade being usual. In fact, the pitting in Stages 5, 6, 7 and 8 looks as though chemical action had taken place, and may be due to certain impurities in the steam becoming active in the presence of moisture.

The same unsatisfactory experience with aluminum bronze in the Curtis blading was found in the 9600-kw. class. On the other hand, the brass blades in Stages 6 to 9 have been found to be in excellent condition from a deterioration point of view, but in several cases have been severely damaged mechanically from various causes and successfully straightened out.

The aluminum-bronze blades in Stages 10, 11 and 12 have proved satisfactory, but in Stage 13 breakages of the blades have occurred. The blades are secured to the wheel by a tee, headed root and fracture frequently occurs across the neck of the tee. The stress at the point is not excessive, approximately 3 tons per sq. in. A new blade was tested at the Government Laboratory and showed an ability to stand 44.9 tons, but an

old blade before fracture had a strength of only 29.8 tons per sq. in. Although there is very little difference in outward appearance, it would seem, therefore, that the material has lost a good deal of its original strength. In some cases the blades have fractured about $1\frac{1}{4}$ in. above the rim of the wheel, i. e., just above the distance piece.

The experience with the 4000-kw. compressor-turbine class was essentially similar to that with the main turbines.

As a general conclusion the author expresses his belief that aluminum bronze is totally unsuitable for use as a blade material in the high-temperature stages, but excellent results have been obtained with it in the low-temperature stages. Five per cent nickel steel has so far given good service where used. Brass stands the temperature well and in some cases has replaced aluminum bronze with satisfactory results.

A similar set of observations is reported on stationary blading. In this connection the writer comes to the conclusion that while cast iron is far from being the best material for inlet nozzles, it is very much cheaper than anything else and for this reason should receive consideration. Steel blades were tried and after running 3000 hours on a 9600-kw. turbine were found to be in excellent condition.

An interesting observation was made in this connection. A nozzle was quite damaged and a test was run with it on the efficiency of the turbine. It was found that actually the turbine was as efficient as if nozzles in good condition had been used. Hence it was obviously sound practice to remove that part which invariably broke away and the nozzle shown in Fig. 11 has therefore been made with a V-shaped portion cut out. Since this nozzle has been used on the main turbines they have been practically free from breakage of nozzle vanes.

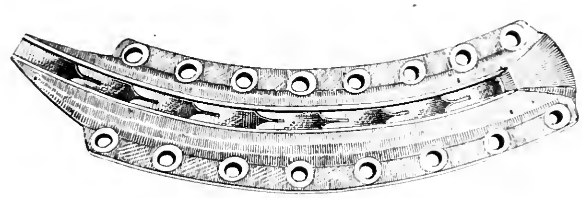

FIG. 11 IMPROVED INLET NOZZLE FOR STEAM TURBINES WITH A PORTION OF THE VANE CUT OUT

Aluminum bronze was originally used on several turbines but proved totally unsuitable, as the metal rapidly disintegrates, owing to temperature. Twenty-five per cent nickel steel stood up well for a time, but became brittle with use. Five per cent nickel steel stands up very well and is now used exclusively for all *main* turbine stationary segment blading.

A similar discussion covers the subject of guide blading. The article also discusses in detail in an interesting manner the question of stresses imposed on the blades. This part cannot be abstracted, because of lack of space. (*The Journal of the South African Institution of Engineers*, vol. 15, no. 8, March 1917, pp. 143-178, 25 figs., *eA*)

BURNING BLAST-FURNACE GAS UNDER BOILERS

Herman C. Siebert, Experimental Engineer of the Duquesne Works, Carnegie Steel Company, presented the following data of experiments with various burners in connection with different boilers giving their air-aspirating characteristics.

The common type of Kennedy blast-furnace-gas burner with its aspirating characteristic is shown in Fig. 12. There is in the furnace an auxiliary bridge wall and a cooled grate between it and the main bridge wall, also a metal screen which permits varying the air opening between boiler and burner. The amount of air is varied by moving the screen in and out over the burner. The characteristic of this type of burner shows that the proper amount of air is established at a pressure of 2 in. when the screen is open. When the screen is closed, the correct amount of air is drawn in at 1 in. gas pressure. At all other gas pressures the air supply is positive or negative in amount of excess. Fig. 13 gives characteristics for two other types of aspirating burners, both similar to that of Fig. 12, except that the proper amount of air is aspirated at a different gas pressure. Fig. 14 shows the characteristic for a special burner and indicates what can be accomplished in the way of air supply if the port area is large enough and is varied to suit the different gas pressures. In this case the air supply was controlled by gas analysis taken from the combustion chamber and the port area.

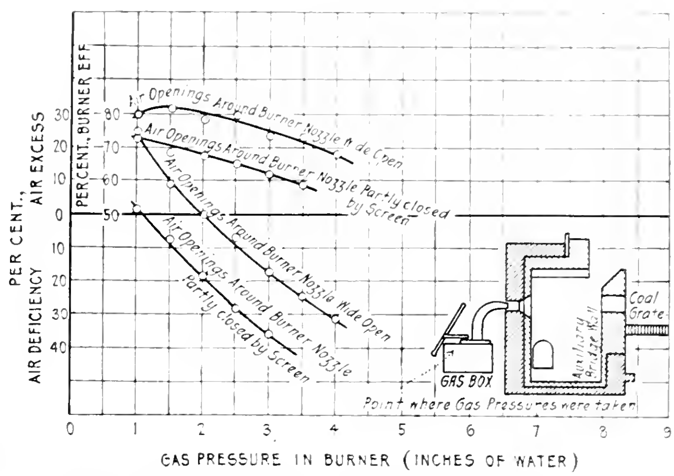

FIG. 12 AIR-ASPIRATING CHARACTERISTICS AND BURNER EFFICIENCIES OF KENNEDY BLAST-FURNACE-GAS BURNERS

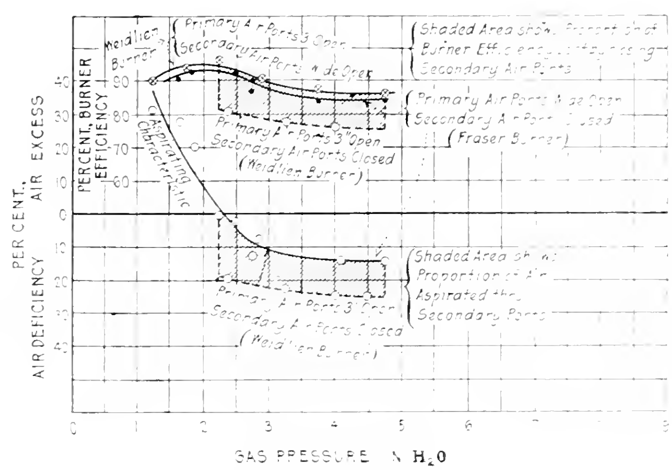

FIG. 13 BURNER EFFICIENCIES AND ASPIRATING CHARACTERISTICS OF KLING-WEIDLEIN-FRASER AND BRADSHAW BLAST-FURNACE-GAS BURNERS

Some experiments were also made with a mixing burner in which an explosive mixture was burned, leaving the nozzle at a velocity greater than the ignition velocity (very low for blast furnace gas). With this type of burner up to 270 per cent of boiler rating was developed.

S. G. Brigel, of the Huessener Engineering Company, Pittsburgh, stated that when running Stirling boilers on loads varying from 130 to 160 per cent, he found stack temperatures

[illegible] temperatures [illegible] between 600 [illegible] boiler, he found [illegible] On the [illegible] with similar temperatures [illegible] Babcock & Wilcox boilers, [illegible] Babcock & Wilcox [illegible] did not rise nearly as quickly [illegible] stack temperature [illegible] A large number of figures taken [illegible] load. [illegible] over 100 Babcock & Wilcox boilers fired [illegible] low stack temperatures ranging from 530 [illegible] fahr. for an average load of 165 per [illegible]

As [illegible] difference in boilers which do or do not [illegible] primary mixing of gas and air, the speaker stated that any burner can be regulated in such a manner that it gives complete combustion with a very low excess of air. But such regulation may require constant attention and in ordinary practice be beyond the capacity of the usual boiler house crew.

In this respect a test which was made at one of the Eastern steel works may be of interest. Two boilers, one equipped with a burner working with secondary air only, the other with a burner working with primary air only, were tested side by side after they had been adjusted in such a manner that both boilers showed 22 per cent CO_2, 1.0 per cent oxygen, and no CO in the combustion chamber. The three successive tests taken on both boilers under identical conditions showed that the boiler utilizing primary air only changed the combustion of the gas in the combustion chamber due to change of gas pressure, to a lower CO_2 of 19 per cent, without any unburnt CO; whilst the boiler working with secondary air went down as low as 17 per cent CO_2 with 6 per cent unburnt CO. This appears to be an excellent illustration of the effect of varying boiler draft on the condition of the combustion chamber. (*Proceedings of the Engineers' Society of Western Pennsylvania*, vol. 33, no. 3, April 1917, pages 167-198, 7 figs., *ep.*)

HYDRAULIC TEST OF PIPE CONNECTIONS

Data of tests conducted under the supervision of F. H. Sibley, Mem.Am.Soc.M.E., in the Machine Construction Laboratory of the University of Kansas. They refer to determination of the relative strength of welded and screwed connections in steel pipe of various sizes when subjected to internal hydraulic pressure. The article briefly describes and illustrates the apparatus used.

The pipe samples ranging from 2 to 4 in. in diameter were cut from standard black steel pipe, the welded specimens being made by operators of a commercial acetylene welding company, while the screw connections were made with malleable-iron couplings and fittings by expert pipe fitters.

The 2 and 3-in. welded specimens failed by splitting along the longitudinal seams of the pipe, the break stopping at the welded section. The 4-in. welded specimens did not fail either in the weld or in the pipe seam (the pressure applied was 5100 lb. per sq. in.). The bursting pressures for the screw connections were considerably below those of the welded specimens and all failed in the fitting. Great difficulty was experienced in testing the screwed connections, because sand holes developed and water leaked through the castings to such an extent that it was almost impossible to reach the point of rupture.

The results of these tests appear to indicate that the strength of a welded-pipe connection is practically the same as that of an unwelded pipe and can be stronger than the rest of the pipe by building up the weld. It appears also that the strength of the welded pipe connection is greater than that of the malleable-iron screwed fitting. (*Iron Age*, vol. 99, no. 18, May 3, 1917, pp. 1070-1071, 1 fig., *e.*)

AIR DRYING FOR BLAST FURNACES, Leon Cammen

Brief characteristics of the main processes of air drying for blast furnaces, both cryogenic and chemical, and description of a process based on the fact that the drying action of a solution of calcium chloride depends on two things: the degree of concentration and the temperature at which the liquor is maintained.

The process involves the use of the following cycle of operations. In the first place, air is passed through a highly concentrated solution of calcium chloride maintained at a proper low temperature and is there freed of such moisture as it may contain. The cold brine which moves in countercurrent to the air after meeting it, proceeds to an evaporator where it is brought back to the initial degree of concentration. It is then sent along a series of cooling coils until it reaches the desired low temperature and is ready to meet the incoming air again. The essential feature of the process is the fact that in the evaporator only a concentration of the brine, and not drying of the salt (which latter is a process requiring a very large specific expenditure of heat), is carried on. This results in the use of comparatively low temperatures and economy of heat consumption.

The brine leaves the refrigerator at a temperature of 16 deg. fahr. and a concentration of 40 per cent. By the time it passes from contact with the incoming air, it has a temperature of, say 25 deg. fahr. and a concentration of 30 per cent. Attention is called in this connection to the fact that the incoming warm and moist air is first met by the comparatively warm brine. While brine of 25 deg. fahr. and 30 per cent concentration is still capable of taking out a large amount of moisture from air at say 80 deg. and a content of 7 grains of water per cu. ft. (the precompression system is apparently used here), the comparatively dry and by then fairly cool air in its last stage of flow passes through a layer of 40 per cent brine at 16 deg. fahr. which is intensely hygroscopic. In this way the most efficient system is adopted both as to the distribution of temperatures and distribution of concentrations. (*Proceedings of the Engineers' Society of Western Pennsylvania*, vol. 33, no. 3, April 1917, pp. 199-204, 1 fig., *d.*)

Mechanical-Efficiency Tests for Machine Tools, G. W. Burley

In dealing with mechanical-efficiency tests for machine tools the writer, in his book recently published, divides the subject into two parts: input determinations and output determinations.

The determination of the amount of input energy may be made in at least three different ways, the electric-motor method, the transmission-dynamometer method, and the cradle-dynamometer method.

The paper discusses in detail the various types of dynamometers and the dynamometer curves referring thereto, such as the transmission dynamometer and the torsion dynamometer.

Among other things, as a method of determining the output of a motor is mentioned the use of a hydraulic piston and cylinder filled with oil or kerosene, and an ordinary pressure or engine indicator. This method does not yield the true output of the motor, however, and does not cover the mechanical losses in the bearings.

An article on the determination of the output of machine tools is promised in a future issue. (*Railway Gazette*, vol. 26, no. 13, March 30, 1917, pp. 386-388, 5 figs., *d*)

Report on Heat-Insulating Materials

Results of tests by Sargent and Lundy, Consulting Engineers, of Chicago, of various heat-insulating materials compared with tests of common firebrick.

The first object of this test was to determine the relative thermal insulating value of materials examined.

The materials were used in dimensions of standard bricks, so as to have the samples equal in this respect. The idea worked on for comparison was to subject the brick to a high temperature at the end *A*, Fig. 1. Then if the top, bottom and sides were thoroughly insulated the heat would be radiated

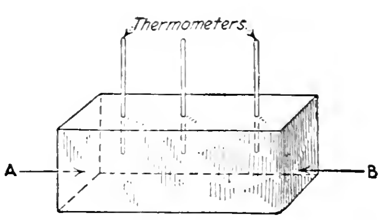

Fig. 15 Diagram Showing Location of Thermometers in Experimental Brick

from the exposed end *B*, and thermometers placed at various distances between *A* and *B* would show a uniform drop in temperature. With the same temperature at *A*, a brick made of a good insulating material would give lower readings on the thermometers placed in the brick than would be the case for a poor insulating material and the temperature gradient would have a different shape.

This process involves the difficulty of thoroughly insulating the top, bottom and sides of the bricks, but in the course of the test it was found that if the top, bottom and side insulation was made practically the same for each material, the comparison would be reliable. The method of testing was to read all thermometers, then place the gasoline torch in position and take readings every 15 or 30 min., the idea being to keep the high temperature source of heat as steady as possible. The gasoline torch did not possess much flexibility and was difficult to regulate satisfactorily.

Another method of test involves the use of an electric heater.

On the whole, it was found that materials have not as good an insulating value at high temperatures as at low ones. To express this variation in insulating value with the temperature, a relation similar to Ohm's law has been derived. The unit taken has been called "the thermal ohm," and is expressed by dividing the temperature difference by the B.t.u. radiated per hour. The values for some of the materials have been calculated and are given in Fig. 16. They show practically straight

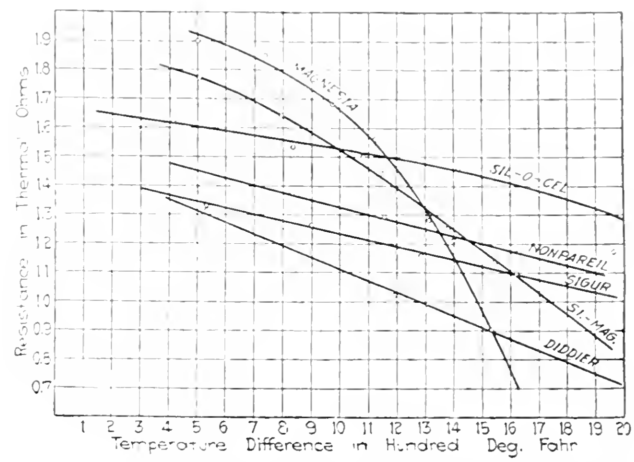

Fig. 16 Curves Showing Heat-Resisting Properties of Various Insulating Materials

lines, except for two materials, of which one, Si-Mag (combination of sigur and magnesia), shows the thermal resistance, which decreases directly as the temperature difference.

Magnesia falls off so rapidly at the high temperature because it becomes disintegrated through a chemical change.

An effort was also made to find the equivalent thickness of material required to give equal insulation, for which purpose it was necessary to demonstrate experimentally the laws of thermal resistance.

Further tests were made to secure some data on the physical properties of insulating materials: in particular, the weight of water absorbed; and it was found that in some cases insulating materials absorbed considerably more than their own weight of water. (*Power*, vol. 44, no. 18, May 1, 1917, pp. 593-596, 14 figs., *e*)

Translation of Formulæ, P. M. Heldt

Discussion of the transformation of equations from one system of units to another, with additional reference to rational equations, which are universally true so long as the rational system of units is used.

If a formula is based on the metric system and the design to which it is applied is in inch units, the question of transformation becomes an important one. Of course, in isolated cases it is possible to convert the inch measurements in the design into metric units, apply the equation and reconvert the result, which would be in metric units, into inch units. Apart from being rather tedious, the process is, however, not conveniently applicable where a number of operations of this nature have to be carried out, and in such cases it becomes necessary to find a simpler way of applying equations derived in units of one system to problems in which the data are expressed in another system.

A certain class of formulæ is universally true so long as a rational system of units is used. Such equations are called rational, and the test of a rational equation consists in substituting for each factor representing a physical quantity, the dimensions in terms of the fundamental quantities (length, mass, time), and seeing whether, when thus transformed, the equation holds true.

In many equations, however, two different units are used for the same quantity. For example, in the equation where the speed of a car is expressed in terms of wheel diameter, engine-speed revolution and gear reduction, two different units of length are generally used—the inch for the wheel diameter and the mile for the distance covered per hour—and two units of time—the minute for the engine speed, and the hour for the car speed. This equation may, however, be transformed into a rational equation by using only one unit of length, say, the inch, and one unit of time, the minute. In this case the equation becomes

$$s = \frac{d\pi n}{r}$$

where s = speed of car, d = wheel diameter, n = engine revolutions per unit of time and r = gear reduction. This equation would give the car speed in inches per minute, but if the engine speed is given in revolutions per minute, the wheel diameter in inches, and the result is required in miles per hour, the equation becomes

$$s = \frac{nd}{336r} \text{m.p.h.}$$

Now, if metric units were used, the wheel diameter given in millimeters and the result required in kilometers per hour, s would be 1.608 times as great (1 mile = 1.608 kilometers) and d 25.4 times as great (1 in. = 25.4 mm.). Therefore, denoting the numerical coefficients by $1/x$,

$$1.608s = \frac{nd \times 25.4}{xr}$$

which would give for x the following equation:

$$x = \frac{336 \times 25.4}{1.608} = 5310$$

and hence the metric formula would read

$$s = \frac{nd}{5310r} \text{ km.p.h.}$$

Of course, it is not necessary to go through all these intermediary steps the next time, and a simple conversion factor $x = 5310$ can be used.

As examples of the application of the methods of transformation of equations from one system of units to another, the writer gives the formula for determining the tax horsepower of automobile motors in Germany, and the formula for the absolute pressure of saturated steam as a function of the absolute temperature in deg. fahr. That part of the article dealing with the latter is here reproduced.

The equation for this relation is:

$$\log p = 10.515354 - (4873.71/t) - 0.00405096t + 0.00000139296t^2$$

Now, suppose that it is desired to transform this equation so the temperature may be inserted in deg. cent. (absolute) and the pressure will be obtained in kg. per sq. cm. We then have:

$$\log(p/14.22) = a - b/0.555t - 0.555\,ct + 0.309dt^2$$
$$\log p - \log 14.22 = a - b/0.555t - 0.555ct + 0.309dt^2$$
$$\log p = \log 14.22 + a - b/0.555t - 0.555ct + 0.309dt^2$$
$$\log p = 1.1529 + a - b/0.555t - 0.555ct + 0.309dt^2$$
$$\text{and}\quad 10.515354 - (4873.71/t - 0.00405096t + 0.00000139296t^2 = 1.1529 + a - b/0.555t - 0.555ct + 0.309dt^2$$

This equation can be satisfied only if the factors in both terms containing the same power of t are equal, that is:

$10.515354 = 1.1529 + a$	$a = 9.3624$
$b/0.555t = 4873.71t$	$b = 2705$
$0.555ct = 0.00405096t$	$c = 0.00729$
$0.309dt^2 = 0.00000139296t^2$	$d = 0.000004515$

Hence the absolute pressure p'' of saturated steam in kg. per sq. cm. is given by the following equation, in which t'' is the absolute temperature in deg. cent: $\log p'' = 9.3624 - 2705/t'' - 0.00729t'' + 0.000004515t^2$. (*Horseless Age*, Engineering Edition, vol. 40, no. 2, April 15, 1917, pp. 1-2 (Engineering Section). *pm*)

Technical Paper 137 of the U. S. Bureau of Mines, of which an abstract will be found in the present issue of THE JOURNAL, is likely to become classical as an investigation of a difficult subject unusually free from unessential details. Among the conclusions established by this investigation, the two probably most important are that the weight of air forced through the fuel bed per pound of fuel burned or gasified is constant; and next, that above a certain distance from the fuel bed there is a large percentage of combustible in the gas and no oxygen to burn it. The investigation is rich in practical suggestions, and must be considered as a valuable contribution to our knowledge of the processes going on in a hand-fired furnace. As regards the numerical values obtained, however, it must be borne in mind before they are used in the design of commercial equipment that they were obtained from an experimental installation using picked fuel.

According to the *Iron Age* for May 3, 1917, J. W. Flavelle, Chairman of the Imperial Munitions Board in Canada, has furnished the Finance Minister with a striking statement showing the extent of the business in munitions built up in Canada with the financial assistance furnished by the Dominion Government. The total value of orders received by the Imperial Munitions Board of Ottawa is $850,000,000, which is equal to the entire international trade of Canada, imports and exports, of 1912. The value of the munitions shipped to March 30 was $470,000,000, the total disbursements to April 30 being $543,000,000. There are 630 factories, chemical and loading plants in operation carrying out the orders of the board. The cash disbursements for March were $41,000,000 and for April will be $43,000,000. Toward the financing of this immense business the Dominion Government has contributed $200,000,000 as a loan to the Imperial Treasury, and arranged with the Canadian banks for advances aggregating $100,000,000.

Official announcement has been made from Ottawa concerning the proposed extensive shipbuilding program, which was foreshadowed some six weeks ago. Orders have been placed for steel ships in Canada up to the full limit of the steel plates available during the next 15 months, and a good many wooden vessels will be built in the Dominion as well. The Dominion Government's part consists in advancing a loan of $10,000,000 to the Imperial Munitions Board, Ottawa. This Board has recently placed large orders for steel plates and will probably be placing additional orders in the near future.

Hours, Fatigue and Health in British Munition Factories

The following outline of the main conclusions arrived at by the British Health of Munition Workers Committee is taken from reprints of the memoranda of this committee made by the Bureau of Labor Statistics of the United States Department of Labor (Bulletin. Whole No. 221, or Industrial Accidents and Hygiene Series, No. 15, April 1917).

This committee was appointed in September 1915 by the Minister of Munitions, and on the basis of evidence taken in various industrial centers has compiled and published some fifteen memoranda dealing with various aspects of the subject. As these memoranda are the work of men especially qualified by technical knowledge and wide experience, they are of particular value in this country at the present time.

As regards Sunday labor, the committee states that the evidence adduced has led it strongly to hold that if the maximum output is to be secured and maintained for any length of time a weekly period of rest must be allowed. Except for quite short periods continuous work in its view is a profound mistake and does not pay—output is not increased.

The committee also makes the significant statement that, in their opinion the higher management even more certainly require definite periods of rest. These individuals have never spared themselves; they carry a heavy burden of responsibility and, moreover, cannot be replaced. The committee has with regret noted among them obvious signs of overwork, and it is of primary importance in the interest of the nation that they should be allowed that rest which is essential to the maintenance of their health.

As regards hours of work the committee calls attention to the fact that overtime fell mainly to the lot of the most highly skilled workers (tool and gage makers, tool setters, etc.) as they are the most difficult to obtain. At one time cases of men working as much as 90 hours per week were met, and while more recently there has been a tendency to reduce the hours, weekly totals of 70 to 80 hours are still frequent. The committee is satisfied that hours such as these cannot be worked with impunity, and most strongly urges that every effort should be made to extend the shift system to this branch of industry as rapidly as possible.

The committee has not found that as yet the strain of long hours has caused any serious breakdown among workers, but there is medical evidence to the effect that long hours are beginning to make themselves felt upon the older men and upon those who suffer from physical infirmity. There is reason for believing, however, that the better food that workers have been able to enjoy in consequence of increased pay has helped to counteract the strain of long hours.

Among the executives and foreman there is evidence of considerable fatigue, and numerous instances have been brought to the notice of the committee where men of this class have had to be allowed special holidays to enable them to recuperate. The committee, therefore, while recognizing that overtime must continue, suggests certain definite restrictions to which it should be submitted, especially in the case of women and girls.

As regards the work of women engaged in moderately heavy work the committee has come to the conclusion that in order to attain a maximum output such women should not work more than 60 hours a week. In fact, an equally good total output would be maintained if the actual working hours were reduced to 56 or less per week. For example, one group of operatives, 17 in number, worked only 51.8 to 62.6 hours per week for five weeks in June and July and during the last three weeks of this period their hourly output was 18 per cent greater than that of another group of 14 operatives who were working the usual long hours.

As regards men engaged in heavy labor, data are not very complete, but as regards boys of 14 to 17, a reduction in the hours of labor from 73.3 to 57 produced an increase of output to the astonishing extent of one-third to one-half, which indicates that the boys must have been overworked by long hours and that a reduction of 8 to 12 hours materially accelerated their rate of production.

On the whole, the committee comes to the conclusion that the hours of labor should be varied between wide limits according to the character of the work performed, and not maintained uniform for all types of labor and for workers of both sexes; and that where long hours of labor on the part of munition workers are necessary, an effort should be made to have them shut up in the factories for as short a time as possible.

In this connection attention is called to the importance of greater promptness in starting work. There can be no necessity for the waste of 25 min. in starting and stopping work, as was the case in a shop under investigation.

The custom in many munitions works is to work for a spell of 5 hours and then after an hour's interval for another spell of 4½ to 5 hours, which leads to spells which are undoubtedly too long in many types of munition work. A better plan would be to arrange for regular rest pauses in between. For instance, a 10-min. break in the middle of the morning and afternoon spells during which the operatives remain at their machines to take tea or other nutriment.

Other memoranda discuss the subjects of industrial fatigue and the special diseases connected with the manufacture of munitions, in particular various forms of poisoning due to the handling of explosives.

A new type of gas engine recently announced is essentially an internal-combustion engine in which air is compressed and mixed with oil which is atomized and ignited by an electric spark. The resulting intensely hot flame of combustion is brought into contact with small quantities of water which cools the gases to a practical working temperature while generating a desirable amount of steam, which, combined with the gases of combustion, enters the power cylinders.

The following claims are made for the engine: Starting without any previous heating, directly with the oil, by hand or electric cranking or by compressed air. Only one spark plug is used, regardless of the number of cylinders. When the engine is under way, the current is turned off. Ignition outfits are not required, as a battery with coil and spark plug will suffice. No heat is lost through water jackets, and little power is wasted in the low-pressure exhaust. The water used is easily condensed and returned to the tank. There are no objectionable carbon deposits. No data of tests of the engine are yet available.

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquiries for further information in connection with articles reported in the Survey.

LIBRARY NOTES

From the Libraries of the Four Founder Societies and the United Engineering Society, in the Engineering Societies Building, New York City

EVERY library has two problems: to collect the material of interest to its patrons and to make it accessible to them with the greatest possible ease.

The history of the Library of the Engineering Societies illustrates an endeavor to meet these two problems. Started as four independent libraries, nothing was more logical than the consolidation of the four into one, with a consequent avoidance of the waste due to duplication. Instead of libraries of civil, mining, mechanical and electrical engineering, we have a library of engineering, equipped to meet the requirements of an inquirer, regardless of the specific subject in which he may be interested.

The Library covers these four main branches of engineering very effectively. It is especially well supplied with periodicals, the most important depository of modern professional literature. The standard reference books and the more important texts are also included. As it becomes possible, the literature of other technologic subjects is being added, in the hope that there may sometime result the ideal collection, able to supply the records of all important previous work on any professional problem which an engineer may meet. To accomplish the ideal will require time and money, but the acknowledged value of the result will more than compensate for the expense. Engineers who wish to assist in the advancement of engineering should consider the benefits which will accrue from additions to the endowment fund of the Library.

Side by side with the extension of the collection, the problem of making it accessible must be faced. Most engineers are too busy to spare the time needed to search through long files of periodicals, or to make copies of desired articles, so it is necessary to provide assistance. To meet this need, the Library Service Bureau has been established as an adjunct to the Library. The Bureau will make lists of references to the articles on any topic, and will, if desired, make copies of them or translate them from other languages. It will send notices of new articles on any topic as they appear in the current periodicals. In fact, its possible forms of service are too various for listing, all that can be said is that it stands ready to undertake any work dealing with professional literature. For this type of work it has been necessary to arrange a schedule of fees, covering the cost of this work to the Library. Information on this subject will be given gladly. The Service Bureau has been of assistance to engineers all over the world, saving time for those to whom libraries are accessible and providing a practical method of reference for those in localities where books are not available.

The future work of the Library is to develop the greatest possible efficiency in these two directions, in the hope that it may ultimately become the largest engineering library in the world, and that it may be able, through a corps of highly trained expert bibliographers, to provide definite references to any material in point. Such an institution will be one of the most valuable aids in the promotion of the profession. It will have an international usefulness, as it will not duplicate the work of any existing institution.

HARRISON W. CRAVER,
Librarian.

U. E. S. Accessions

ADEQUATE FREIGHT RATES A NECESSITY TO ADEQUATE RAILROAD SERVICE. By W. W. Atterbury. *1917.* Purchase.

AMERICAN ELECTROCHEMICAL SOCIETY. Transactions. vol. 29. *South Bethlehem, 1916.* Purchase.

AMERICAN SOCIETY OF CIVIL ENGINEERS. Constitution and List of Members. February, 1917. *New York, 1917.* Gift of A.S.C.E.

AMERICAN UNIFORM BOILER LAW SOCIETY. Condensed report of the American Uniform Boiler Code Congress, Washington, Dec. 4-6, 1916. *Erie, Pa., 1916.* Gift of Society.

APPORTIONMENT OF RAILROAD EXPENSES AND PROPERTY VALUES ON BASIS OF USE. By A. M. Sakolski. Reprint from the Journal of Accountancy, Aug., 1916. Gift of author.

AQUABAR COMPANY. Concrete tile roofing. Descriptive catalogue. Philadelphia, n.d.
——— Specifications No. 11, covering the use of no. 1 compound in waterproofing mass concrete for foundation walls, subways, etc.
——— No. 12, covering the use of no. 1 compound in waterproofing masonry and concrete walls and floor with cement plaster coat for foundation walls, floors, etc.
——— No. 15, covering the use of no. 1 compound for waterproof cement stucco on brick and hollow tile walls. Gift of Aquabar Company.

AZIMUTH. Ed. 2. By George L. Hosmer. *New York. John Wiley & Sons, Inc., 1916.* Price $1. Gift of publisher.

THE BAROMETRICAL DETERMINATION OF HEIGHTS: A Practical Method of Barometrical Levelling and Hypsometry for Surveyors and Mountain Climbers. Ed. 2. By F. J. B. Cordeiro. *New York. Spon & Chamberlain, 1917.* Price $0.50. Gift of publisher.

BRACHYCERATOPS. A ceratopsian dinosaur from the two miocene formations of Montana. U. S. Geological Survey. Professional paper 103. *Washington, 1917.*

BUREAU OF RAILWAY ECONOMICS. List of References on Valuation of Railways, Aug. 1, 1916. *Washington, 1916.* Gift of Bureau of Railway Economics.

CARNEGIE LIBRARY OF PITTSBURGH. Classified Catalogue. 1907-11. vols. 6-8. *Pittsburgh, 1914.* Gift of Carnegie Library of Pittsburgh.

CENTRAL STATION ELECTRIC SERVICE: Its Commercial Development and Economic Significance as Set Forth in the Public Addresses (1897-1914), by Samuel Insull, with an Introduction by William Eugene Kelly. *Chicago* (privately printed), *1915.* Gift of author.

CHARACTERISTICS OF UNIFLOW ENGINE GENERATING UNITS. By E. Hagenlocher. Reprint from *Electrical World*, Feb. 10, 1917. Gift of author.

CHEMICAL GERMAN. An introduction to the study of German chemical literature. By F. C. Phillips. Ed. 2. *Easton, Pa., 1915.* Purchase.

CITY MANAGER AND CITY ENGINEER-MANAGER. Plans of Municipal Government. By Kenyon Riddle. *Abilene, Kansas, n. d.* Gift of author.

CLAY DEPOSITS NEAR MOUNTAIN GLEN, UNION COUNTY, ILL. Ill. State Geological Survey. Extract from Bulletin no. 36. *Urbana, 1917.* Purchase.

COAL TAR AND AMMONIA. Ed. 5. 3 vols. By George Lunge. *New York, 1916.* Purchase.

[illegible] Reprinted [illegible] Gift of S. [illegible]

[illegible] BIBLIOGRAPHY [illegible] Paper 116. *Washington.* [illegible]

[illegible] of a Bridge and a Discussion [illegible] Specification. By E. E. Howard. *New York* [illegible] 1916. Price, $1. Gift of publisher.

[illegible] By [illegible] *San Francisco, 1916.* Purchase.

[illegible] Constitution, Executive Staff, Member Committees [illegible] to 1917. *Chicago, 1917.* Gift of Club.

[illegible] SPECIFICATIONS. By J. H. Montgomery. *New York,* [illegible] Purchase.

[illegible] OF WATER GAS. By J. Stephenson. *Columbia, S. C., 1916.* Purchase.

ENGINEERING ANALYSIS OF A MINING SHARE. By J. C. Pickering. *New York, McGraw Hill Book Co., Inc., 1917.* Price $1.50. Gift of publisher.

ENGINEERS' CLUB OF BOSTON. By-laws, Officers and List of Members April 2, 1917. Gift of Club.

EXPERIMENTAL ENGINEERING AND MANUAL FOR TESTING. By R. C. Carpenter. Ed. 6. *New York, John Wiley & Sons, 1907.* Gift of publisher.

FEDERAL VALUATION OF COMMON CARRIERS. By J. P. Nelson. n. p. *1916.* Gift of Clemens Herschel.

FEDERAL VALUATION OF THE RAILROADS IN THE UNITED STATES. Circular communication to the chairmen of valuation committees, in reference to the supplement to Interstate Commerce Commission valuation order no. 7—schedules of land. Apr. 10, 1917. Gift of Clemens Herschel.

FEDERAL VALUATION OF THE RAILROADS IN THE UNITED STATES. Statement prepared by H. C. Phillips, general secretary, of the developments in connection with Federal Valuation, as of April 20, 1917. Gift of Clemens Herschel.

FRYE'S TABLES FOR ASCERTAINING THE VALUE OF GOLD QUARTZ SPECIMENS. By Jason S. Frye. *Downieville, Cal., 1916* (privately printed). Gift of author.

GASOLINE AND HOW TO USE IT. By G. A. Burrell. Boston, Oil Statistical Society, Inc., 1916. Gift of publisher.

GENERAL INSTRUCTIONS AND METHODS OF ANALYSIS AND CHEMICAL CONTROL FOR USE IN THE FACTORIES OF THE CUBAN-AMERICAN SUGAR CO. By Guilford L. Spencer. N. Y., The Cuban-American Sugar Co., *1916.* Gift of publisher.

GEOGRAPHIC TABLES AND FORMULAS. Ed. 4. U. S. Geological Survey. Bulletin no. 650. *Washington, 1916.* Purchase.

GREAT BRITAIN. ADVISORY COMMITTEE FOR AERONAUTICS. Technical Report, 1912-13. *London, 1914.* Purchase.

GROUPING OF PUBLIC BUILDINGS AND GARDENS, with Adjoining Water Front, Excursion Docks and Union Station for the City of Buffalo. Buffalo, n.d. Gift of George Cary.

A HANDBOOK FOR CANE-SUGAR MANUFACTURERS AND THEIR CHEMISTS. By Guilford L. Spencer. Ed. 5, enl., N. Y., John Wiley & Sons, Inc., London, Chapman & Hall, Ltd., *1916.* Gift of publisher.

A HANDBOOK OF BRIQUETTING. By G. Franks. Translated by Fred C. A. H. Lantsberry. vol. 1. The Briquetting of Coals, Brown Coals, and other Fuels. Phil., *J. B. Lippincott Co. London, Charles Griffin & Co., Ltd., 1917.* Gift of the publisher.

HANDBOOK OF ENGINEERING MATHEMATICS. By W. E. Wynne and Wm. Spraragen. *New York, 1916.* Purchase.

HAWKINS ELECTRICAL GUIDE. Questions, answers and illustrations. nos. 7, 8, 9. *New York, 1914-15.* Gift of Theo. Audel & Company.

HENDRICKS' COMMERCIAL REGISTER OF THE UNITED STATES FOR BUYERS AND SELLERS. Twenty-fifth Annual Edition, N. Y., *S. E. Hendricks Co., Inc., 1916.* Gift of publisher.

A HUMAN SIDE OF THE RAILWAYS. An authorized interview with Cardinal Gibbons by Ballard Dunn, March 1, 1917. Reprinted from *The Outlook, Feb. 28, 1917.* Purchase.

THE INORGANIC CONSTITUENTS OF MARINE INVERTEBRATES. U. S. Geological Survey. Professional Paper 102. *Washington, 1917.* Purchase.

INSTITUTE OF METALS. Journal. vol. xvi. *London, 1916.* Purchase.

INSTRUCTIONS TO LOCATING ENGINEERS AND FIELD PARTIES. By F. Lavis. *New York, McGraw-Hill Book Co., Inc., 1916.* Gift of author.

INTERSTATE COMMERCE COMMISSION. Hearings before, on March 19-21, 26-31, 1917. Gift of Clemens Herschel.

IRON AND STEEL INSTITUTE JOURNAL. vol. xciv. *London, 1916.* Purchase.

LABORATORY MANUAL OF BITUMINOUS MATERIALS FOR THE USE OF STUDENTS IN HIGHWAY ENGINEERING. By Prevost Hubbard, N. Y., *John Wiley & Sons, 1916.* Gift of publisher.

LARGE ELECTRIC POWER STATIONS, THEIR DESIGN AND CONSTRUCTION. English translation. By G. Klingenberg. *New York, 1916.* Purchase.

A MANUAL OF FIRE PREVENTION AND FIRE PROTECTION FOR HOSPITALS. By Otto R. Eichel. *New York, John Wiley & Sons, 1916.* Gift of publisher.

MASSACHUSETTS DEPARTMENT OF WEIGHTS AND MEASURES. Measurements for the Household. Ed. 2, Jan. 1917. *Boston, 1917.* Gift of Department of Weights and Measures.

MCCLINTIC-MARSHALL CONSTRUCTION COMPANY. Report on the claim against the Isthmian Canal Commission, submitted to the Senate pursuant to act of Congress of June 24, 1914. By G. W. Goethals. *Washington, 1916.* Gift of Panama Canal Press.

MCGRAW ELECTRIC RAILWAY LIST, February 1917. *New York, 1917.* Purchase.

MECHANICAL HANDLING AND STORING OF MATERIAL. By Geo. F. Zimmer. *New York, 1916.* Purchase.

THE MECHANISM OF THE LINOTYPE. By John S. Thompson. Ed. 6. *The Inland Printer Co., 1916.* Gift of publisher.

METAL SPINNING. By F. D. Crawshaw. *Chicago, 1909.* Purchase.

MICHIGAN GEOLOGICAL AND BIOLOGICAL SURVEY. Biennial Report of the Director and report on retracement and permanent monumenting of the Michigan-Ohio boundary. *Lansing, 1916.* Purchase.

MINERAL RESOURCES OF MICHIGAN WITH STATISTICAL TABLES OF PRODUCTION AND VALUE OF MINERAL PRODUCTS FOR 1915 AND PRIOR YEARS. Michigan Geological & Biological Survey. Publication 21, Geol. Ser. 17. *Lansing, 1916.* Purchase.

MINING MANUAL AND MINING YEAR BOOK, 1917. By Walter R. Skinner. *London, 1917.* Purchase.

MUNICIPAL ACCOUNTING. By DeWitt Carl Eggleston. *New York, The Ronald Press Co., 1914.* Gift of publisher.

MUNICIPAL ENGINEERING PRACTICE. By A. Prescott Folwell. N. Y., *John Wiley & Sons, Inc., 1916.* Gift of publisher.

MUNICIPAL INDEX, 1916. *New York, 1917.* Purchase.

MINE GASES AND VENTILATION: A Reference Handbook Combining Theory and Practice of Coal Mining. By J. T. Beard. *New York. Hill Publishing Co., 1916.* Gift of author.

NATIONAL ADVISORY COMMITTEE FOR AERONAUTICS. Annual Report. Second, 1916. *Washington, 1917.* Gift of Committee.

NATIONAL ELECTRIC LIGHT ASSOCIATION. Papers, Reports and Discussions, 39th Annual Convention. Accounting, Commercial, Electric Vehicle, General, Technical and Hydro-electric. 5 vols. *May 1916.* Purchase.

NAVAJO COUNTRY. U. S. Geological Survey. Water Supply Paper 380. *Washington, 1916.* Purchase.

NEW YORK STATE ENGINEER AND SURVEYOR. Annual Report, vol. 1, 1916. *Albany, 1917.* Gift of State Engineer and Surveyor.

NEW YORK STATE LIBRARY. Annual Report 98, 1915. *Albany, 1917.* Gift of University of the State of New York.

NEW YORK TIMES INDEX. vol. v, Jan.-March 1917. *New York, 1917.* Purchase.

Ozone: Its Manufacture, Properties and Uses. By A. Vosmaer. *New York, 1916.* Purchase.

Penalties and Liquidated Damages. By W. B. King. Reprinted from *Architectural Forum*. Feb. 1917. Gift of King & King.

Pennsylvania. Report of the Commission to Investigate the Increase in the Cost of Anthracite Coal in the Commonwealth of Pennsylvania. To the Governor and Legislature, pursuant to Joint Resolution of June 15, 1915. Purchase.

——— Department of Forestry. Report 1914-15. *Harrisburg, 1916.* Purchase.

Practical Notes on Hydrographic and Mining Surveys. By W. H. Hearding. *Milwaukee, 1872.* Purchase.

Practical Sheet Metal Duct Construction; a Treatise in the Construction and Erection of Heating and Ventilating Ducts, by William Neubecker. N. Y. *The Sheet Metal Publishing Co., 1916.* Gift of publisher.

Profile Surveys Along Henrys Fork, Idaho and Logan River and Blacksmith Fork, Utah. U. S. Geological Survey. Water Supply Paper 420. *Washington, 1916.* Purchase.

Profile Surveys in the Colorado River Basin in Wyoming, Utah, Colorado and New Mexico. U. S. Geological Survey, Water Supply Paper 396. *Washington, 1917.* Purchase.

Profile Surveys in 1915 Along the Rio Grande, Pecos River, and Mora River, New Mexico. U. S. Geological Survey, Water Supply Paper 421. *Washington, 1916.* Purchase.

Profile Surveys in 1915 in Skagit River Basin, Washington. U. S. Geological Survey. Water Supply Paper 419. *Washington, 1916.* Purchase.

Profile Surveys of Rivers in Wisconsin. U. S. Geological Survey. Water Supply Paper 417. *Washington, 1917.* Purchase.

Progress of Federal Valuation. By A. M. Sakolski. Gift of author.

Public Office. From a Civil Service and Business Point of View. By John J. Hopper. *Albany, 1917.* Gift of Register of New York County.

Pueblo, Colo. City Controller. Annual Statement, 1916. *Pueblo, 1916.* Gift of City Controller.

Questions and Answers Relating to Modern Automobile Design, Construction, Driving and Repair. By Victor W. Page. *New York. The Norman W. Henley Pub. Co., 1917.* Gift of publisher.

Railway Statistics of the United States of America, 1916, compared with the official reports for 1915 and recent statistics of foreign railways. By Salson Thompson. *Chicago, 1917.* Gift of author.

Railway Track Economics; a Tabloid Treatise Upon Railroad Problems, by August E. Liebmann, Chicago (privately printed), 1916. Gift of author.

Relations of Railways and Shippers in the United States. An address by A. W. Thompson at the Annual Dinner of the Portland Cement Association. *Dec. 13, 1916.* Purchase.

River Discharge, by Hoyt, John Clayton and Nathan Clifford Grover, 4th ed. rev. and enl. N. Y., *John Wiley & Sons, Inc.; London, Chapman & Hall, Ltd., 1916.* Gift of publisher.

Rules for Docking Vessels in Dry Docks Belonging to the Panama Canal. *Mount Hope, 1916.* Gift of Panama Canal Press.

A Schedule of Civic Surveys. By A. C. Comey. Bulletin No. 5, May, 1916, Commonwealth of Massachusetts. Gift of author.

Society of Engineers. Transactions. 1916. *London, 1916.* Purchase.

Some Comments on Federal Valuation of Common Carriers. By J. P. Nelson. Spoken before the Richmond Railroad Club, Feb. 12, 1917. Gift of Clemens Herschel.

Spanish. Commercial and Professional. By Teodoro S. Romero. *Philadelphia, 1916.* Purchase.

Spons' Electrical Pocket-Book; a Reference Book of General Electrical Information, Formulæ and Tables for Practical Engineers, by Walter H. Molesworth. N. Y., *Spon & Chamberlain; London. E. & F. N. Spon, Ltd., 1916.* Gift of the publisher.

Standard Methods for the Examination of Water and Sewage, Ed. 3, Boston; American Public Health Association, 1917. Gift of publisher.

Steam Boilers; their theory and design. By H. de B. P[illegible]. Ed. 5. *New York City, [illegible]* Purchase.

Steam Turbines; a Treatise Covering U. S. Naval Practice. By G. J. Meyers. *Annapolis, Md. The U. S. Naval Institute, [illegible]* Gift of publisher.

Straight Line Engineering Diagrams. By Manifold & Poole. *San Francisco, n. d.* Purchase.

Surface Waters of Massachusetts. U. S. Geological Survey. Water Supply Paper 415. *Washington, 1916.* Purchase.

Surface Water Supply of the United States, 1913. Part XI. Pacific Slope Basins in California. Water Supply Paper 361.

——— 1914. Part XII. North Pacific Drainage Basins. Water Supply Paper 392.

——— 1915. Part II. South Atlantic and Eastern Gulf of Mexico Basins. Water Supply Paper 402. Part VII. Lower Mississippi River Basin. Water Supply Paper 407. *Washington, 1916, 1917.* Purchase.

Telegraphy: a Detailed Exposition of the Telegraph System of the British Post Office. Ed. 3. By T. E. Herbert. *New York. The MacMillan Co., 1916.* Gift of publisher.

Telephony. A comprehensive and detailed exposition of the theory and practice of the telephone art. By Samuel G. McMeen and K. B. Miller. *Chicago, 1916.* Purchase.

Thermochemistry. By Julius Thomsen, translated from the Danish by Katherine A. Burke. *New York, 1908.* Purchase.

The Thirteenth Amendment and the General Railway Strike. By B. Lee. Reprinted from the Virginia Law Review. *March, 1917.* Purchase.

Triangulation and Primary Traverse, 1913-1915. U. S. Geological Survey. Bulletin 644. *Washington, 1916.* Purchase.

Trus Con Laboratories. Architects' specifications hand book of waterproofing dampproofing, technical paint, etc. *Detroit, n. d.* Gift of Trus Con Laboratories.

Trussed Concrete Steel Company. Kahn Road Book devoted to concrete roads and pavements. *Youngstown, 1916.* Gift of Trussed Concrete Steel Co.

Tube Milling; a Treatise on the Practical Application of the Tube Mill to Metallurgical Problems, by Algernon Del Mar. N. Y. *McGraw-Hill Book Co., Inc., 1917.* Gift of publisher.

Unified Accounting Methods for Industrials. By C. E. Woods. *New York, 1917.* Purchase.

U. S. Geologic Atlas. Eureka Springs-Harrison Folio, Arkansas-Missouri. Folio 202. *Washington, 1916.*

——— ——— Tolchester Folio, Maryland. Folio 204. *Washington, 1917.* Purchase.

U. S. Geological Survey. Annual Report of the Director. 37th. *Washington, 1916.* Purchase.

U. S. Reclamation Service. General Reclamation Circular. Laws and regulations relating to the reclamation or arid lands by the United States. *Washington, 1916.*

PERSONALS

IN these columns are inserted items concerning members of the Society and their professional activities. Members are always interested in the doings of their fellow-members, and the Society welcomes notes from members and concerning members for insertion in this section. All communications of personal notes should be addressed to the Secretary, and items should be received by June 16 in order to appear in the July issue.

CHANGES OF POSITION

HORACE H. NEWSOM, formerly factory manager of the Perfection Spring Company, Cleveland, O., has become affiliated with the Standard Parts Company of the same city.

L. C. WELCH, formerly connected with The Imperial Oil Company, Ltd., Sarnia, Canada, has become identified with The Midwest Refining Company, Casper, Wyoming.

JOHN D. RIGGS, formerly associated with the Indestructible Wheel Company, Lebanon, Ind., has entered the employ of the Link-Belt Company, Indianapolis, Ind.

GEORGE B. PRESTON, formerly assistant professor of steam engineering, Columbia University, New York, has become associated with The J. G. White Engineering Corporation, New York.

I. ALBERT BAUM has severed his connection as city engineer of Texarkana, Ark., and has accepted the position of assistant manager of the LaSalle Engineering Company, Chicago, Ill.

GEORGE F. READ has severed his connection with E. I. duPont de Nemours and Company, Penns Grove, N. J., and has accepted a position with The Celluloid Company of Newark, N. J.

ALBERT BUENGER, formerly heating and ventilating engineer with Smith Hinchman and Grylls, Detroit, Mich., has become identified with the Charles L. Pillsbury Company, St. Paul, Minn.

ULRIC THOMPSON, JR., formerly chief engineer of the T. A. Gillespie Company's plant at Parlin, N. J., has become associated with Westinghouse, Church, Kerr and Company of New York.

EUGENE L. BROWN, JR., formerly chief deputy inspector of boilers and elevators of the City of St. Louis, Mo., has accepted the position of engineer with the Illinois Stoker Company of Alton, Ill.

BARRETT W. MORRISON has left the employ of the Westinghouse Machine Company, East Pittsburgh, Pa., and has accepted a position with the Great Western Sugar Company, Billings, Mont.

RUSSELL J. HAWN, formerly with the Ohio Chemical Company, Springfield, Ohio, in the capacity of manager, has become associated with the Oakland Chemical Company, Rossville, S. I., N. Y.

EMILE H. NATE has become consulting engineer with Hammerston and Nate, New York. He was, until recently, associated with the Nate-Earle Company, Inc., New York, as president and treasurer.

W. R. CRUTE has assumed the duties of chief engineer of the Champion Fiber Company, Canton, N. C. He was formerly engineer with the Norfolk and Western Railway Company, Pocahontas, Va.

ARTHUR L. JENNINGS, formerly connected with the McGill Metal Company, Valparaiso, Ind., as general manager, has accepted the position of treasurer of the John T. Robinson Company, Boston, Mass.

JOHN J. EASON, formerly assistant superintendent of the mechanical division of the Panama Canal, Balboa, Canal Zone, has been appointed assistant shop superintendent at the Navy Yard, Norfolk, Va.

WELLES H. SELLEW, formerly mechanical engineer with the Canadian Car and Foundry Company, Kingsland, N. J., has accepted a similar position with the American Chicle Company, Long Island City, N. Y.

HARRY A. WARD, formerly in the employ of the Sterling Blower Company, New York, as sales engineer, has taken up the duties of engineer of plants with the American Oak Leather Company, Cincinnati, O.

JACOB L. MUELLER, until recently metallurgist with the Springfield Facing Company, Springfield, Mass., has accepted the position of mechanical engineer with the American Chain Company, Inc., Bridgeport, Conn.

GEORGE S. BARKER, formerly designing draftsman of the Niles-Bement-Pond Company, New York, has accepted the position of mechanical engineer with the Lucey Manufacturing Corporation, Chattanooga, Tenn.

HARRY O. HAGSTROM has become affiliated with the Elevator Supplies Company, Inc., Philadelphia, Pa. He was until recently connected with the Elevator Supply and Repair Company, New York, as sales engineer.

GRAHAM H. ANTHONY has severed his connection with the William L. Gilbert Clock Company, Winsted, Conn., as equipment superintendent, to take a position with The Allen Manufacturing Company, of Hartford, Conn.

BENJAMIN C. SHAW has accepted a position with the Boston Duck Company, Bondsville, Mass. He was formerly associated with the Warren Cotton Mills, West Warren, Mass., in the capacity of master mechanic.

ERNEST H. HAWKINS, formerly connected with the Allis-Chalmers Manufacturing Company, Philadelphia, Pa., has become associated with the purchasing department of E. I. duPont de Nemours and Company, Wilmington, Del.

ARTHUR D. STANCLIFF, until recently associated with the Hawkeye Portland Cement Company, Des Moines, Ia., has assumed the duties of superintendent of the Western States Portland Cement Company, Independence, Kan.

LOUIS H. MESKER has become affiliated with The Cleveland Milling Machine Company, Cleveland, O. He was until recently connected with Kearney and Trecker Company, Milwaukee, Wis., in the capacity of sales manager.

JAMES H. OAK has resigned his position as general foreman of the New England Westinghouse Company, Chicopee Falls, Mass., and has assumed the duties of superintendent of the National Automatic Machine Company, Brattleboro, Vt.

JOHN J. CHISHOLM has resigned his position as superintendent of power for the Tennessee Coal, Iron and Railroad Company at Ensley, Ala., and has taken up similar duties with the New Orleans Railway and Light Company, New Orleans, La.

CLAYTON A. SWIGGETT, formerly associated with the Western States Portland Cement Company, Independence, Kan., as superintendent, has entered the employ of the Lehigh Portland Cement Company, Iola, Kan., in a similar capacity.

EDGAR T. SPIDY, until recently connected with the Canadian Pacific Railway Shops, Winnipeg, Canada, in the capacity of shop engineer, has assumed the duties of production engineer with the Canadian Ingersoll-Rand Company, Sherbrooke, Que., Canada.

ROBERT H. WALLACE, until recently connected with the Remington Arms and Ammunition Company, Bridgeport, Conn., in the capacity of experimental engineer, has assumed the duties of shop superintendent of the Bailey Meter Company, Boston, Mass.

LEE E. WALKER has accepted a position with the Haynes Stellite Company of Kokomo, Ind., with headquarters in Philadelphia, Pa. He was until recently connected with the Baldwin Locomotive Works, Eddystone, Pa., as foreman of the French Shell Shop.

FRANK H. SCHUBART, formerly district manager for the Wheeler Condenser and Engineering Company, St. Louis, Mo., has become associated with the Union Electric Light and Power Company of the same city, as assistant chief engineer of power plants.

EDGAR G. SCOTT, until recently connected with Ludlow Manufacturing Associates, Ludlow, Mass., in the capacity of superintendent of power and repair shops, has become identified with the Joseph Campbell Company, Camden, N. J., as mechanical engineer.

AUGUSTUS W. SHALLCROSS has severed his connections as draftsman and designer with the Layne and Bowler Company, Houston, Tex., and has accepted the position of designer and chief draftsman with R. P. Clark and Company, engineers of the same city.

GEORGE H. JEWELL has resigned as manager of sales of the Lytton Manufacturing Corporation, to become identified with the Chicago office of the Builders Iron Foundry of Providence, R. I., manufacturers of Venturi meters and special recording instruments.

ROBERT W. ELLINGHAM has become affiliated with The Bilton Machine Tool Company, Bridgeport, Conn., a new corporation formed by the consolidation of The Standard Manufacturing Company and The Parsons Foundry Company. Mr. Ellingham was until recently connected with the Remington Arms and Ammunition Company, Bridgeport, Conn., in the capacity of assistant superintendent.

ANNOUNCEMENTS

PERCY H. THOMAS has been granted a patent for a system of electrical distribution.

PAUL WEEKS has become associated with the Holt Engineering Company, of Stockton, Cal.

RALPH BLUMENFELD has entered the employ of the Bayonne Steel Casting Company, Bayonne, N. J.

WALTER J. WARDER, JR., has accepted a position with [illegible] Brothers and Company, Chicago, Ill.

AMASA M. HOLCOMBE has accepted a commission as Captain in the Ordnance Section of the Officers' Reserve Corps, U.S.A.

J. M. SPITZGLASS, mechanical engineer of Chicago, Ill., has become associated with the Republic Flow Meters Company of Chicago, Ill.

ALEXANDER ENGBLOM, formerly mechanical superintendent of Sidney Blumenthal and Company, Shelton, Conn., expects to go to Sweden shortly.

[illegible] has been commissioned as [illegible] Officers' Reserve Corps, and [illegible] Kansas.

[illegible] engineer with the International [illegible] has been transferred to Milwaukee, Wis[illegible] the Milwaukee Works of the company.

W[illegible] F. D[illegible] and CHARLES P. STEINMETZ have been elected [illegible] of the American Philosophical Society. Professor Durand [illegible] elected a member of the National Academy of Sciences.

DANA W. WILBER, of Rochester, N. Y., has been ordered to Madison Barracks, New York, with recommendation for the rank of Captain in the Engineer Officers' Reserve Corps, from the War Department.

CLARENCE E. BILTON, president of the Bilton Machine Tool Company, Bridgeport, Conn., has been elected president of the Manufacturers' Association of that city, to succeed James G. Ludlam, resigned.

WILLIAM D. ENNIS, since 1907 head of the department of mechanical engineering in the Polytechnic Institute, Brooklyn, N. Y., has been appointed Major of the Ordnance Section, Officers' Reserve Corps, under date of May 5, 1917.

EDWIN J. PEIRCE, JR., production engineer of New York, has returned from a trip to Kansas City, Mo., in the interests of the Automatic Bookkeeping Register Company. Mr. Peirce is making a specialty of organizing for increased production.

FREDERICK U. CONARD, formerly with the Jennings Lace Works, Brooklyn, N. Y., and now employed by the Public Service Gas Company of Newark, N. J., is at present on leave of absence on account of military duties. He holds a commission as Second Lieutenant in the Engineer Officers' Reserve Corps and is stationed at Fort Oglethorpe, Tenn.

CHARLES WHITING BAKER has retired from the position of editor of *Engineering News-Record* and has become consulting editor of the journal. FREDERICK E. SCHMITT, who was associate editor of *Engineering News* from 1902 until its consolidation with *Engineering Record* as *Engineering News-Record*, a few weeks ago, succeeds Mr. Baker as editor.

JOHN P. FLIPPEN, formerly chief engineer of the C. H. Wheeler Manufacturing Company, Pittsburgh, Pa., is now district manager of that company's interests in Western Pennsylvania, Ohio and West Virginia, with offices in Cleveland and Pittsburgh. Mr. Flippen is operating in conjunction with the Baker Dunbar Allen Company, contracting engineers.

FRED. A. GEIER, president of the Cincinnati Milling Machine Company, Cincinnati, O., and a former trustee of the University of Cincinnati, has made a gift of \$25,000 to the University which will be known as the Fred. A. Geier Students' Loan Fund. The annual interest is to be used to provide loans to students of the coöperative engineering course who need financial assistance.

WILLIAM H. WINTERROWD, assistant chief mechanical engineer of the Canadian Pacific Railway, has just returned to this continent after an absence abroad of over $3\frac{1}{2}$ months. He accompanied George Bury, senior vice-president of the Canadian Pacific Railway to Russia, which was visited at the request of the British and Russian Governments in connection with transportation problems.

APPOINTMENTS

EDWARD FLAD, consulting engineer, of St. Louis, has been appointed to succeed John Kennish on the Public Service Commission of Missouri.

ARTHUR S. HAWKS, formerly assistant chief engineer of the Busch-Sulzer Bros.-Diesel Engine Company, St. Louis, Mo., has been appointed chief engineer in the company.

JULIAN KENNEDY, Vice-President, Am.Soc.M.E., of Pittsburgh, has been appointed a member of the State Committee on Public Safety by M. G. Brumbaugh, Governor of Pennsylvania.

WILLIAM SMITH has been appointed general master mechanic of the Brandywine Works of the Midvale Steel Company, Coatesville, Pa. He was formerly associated with the company as assistant to superintendent of the special forge department.

CHARLES R. RICHARDS, professor of mechanical engineering at the University of Illinois, and head of the department since 1911, has been appointed dean of the College of Engineering and director of the Engineering Experiment Station to succeed Dr. W. F. M. Goss, who has become president of the Railway Car Manufacturers' Association.

AUTHORS

W. KNIGHT is the author of an article on Explanation of the Failures of Materials, which appears in the May 10 number of the *American Machinist*.

J. PAUL CLAYTON has contributed an article entitled Electric Cooking in Small Cities, to the May 5 issue of the *Electrical Review and Western Electrician*.

WILLIAM T. DONNELLY has contributed an illustrated article on the Problem of the Wooden Cargo Ship, to the May issue of *International Marine Engineering*.

C. F. HIRSHFELD presented a paper on Some Low-Temperature Electrothermic Processes at the Detroit convention of the American Electrochemical Society, May 2 to 5.

JOHN A. MATHEWS presented a paper on Comments on the Electrical Steel Industry at the May 2 to 5 meeting of the American Electrochemical Society, held in Detroit, Mich.

SAMUEL S. WYER is the author of Electrolysis Damages from Single-Trolley Electric Railways which appears in Vol. 23, No. 11 of *Case and Comment*, The Lawyer's Magazine.

H. COLE ESTEP, editorial director of the Penton Publishing Company, Cleveland, O., addressed the Philadelphia Foundrymen's Association, May 2, on The Cleaning of Castings.

ALLEN F. BREWER is the author of an interesting article in the *Engineering News-Record* for April 19, comparing the suitability and cost of portable frame buildings with canvas tents for use in modern military encampments.

RICHARD G. WILLIAMS presented a paper on The Grinding Wheel—A Connected Link between the Electric Furnace and the Automobile, at the 31st general meeting of the American Electrochemical Society, held in Detroit, May 2 to 5.

VICTOR W. ZILEN is the author of an article on Reversible Steam Turbine for Driving Locomotives, which appears in the May 1 issue of *Power*. This article deals with the preliminary design of steam turbines and with locomotive turbine performance.

CLAUDE HARTFORD has contributed articles on Up-to-Date Methods of Selling Steam, and the New Station of the New York Steam Company, which appear in the April issue of *The Heating and Ventilating Magazine* and the April 15 number of *The Bulletin of the National District Heating Association*, respectively. He is also the author of an article entitled New High-Pressure Central Steam Plant, which appears in the February 6 issue of *Power*.

THE NEW BOOKS

ALL books received by The Journal will be listed under this heading, generally accompanied by brief descriptive notes. Works of special importance to mechanical engineers will be commented on at length by members and others peculiarly qualified by reason of their experience and training.

Engineering Chemistry

Engineering Chemistry. By Thomas B. Stillman, M.Sc., Ph.D. Late Professor of Engineering Chemistry in the Stevens Institute of Technology, etc. The Chemical Publishing Co., Easton, Pa., 1916. Cloth, 5¾ x 8¾ in., 760 pp., 150 illustrations. $5.

The present edition of Engineering Chemistry is fully up to the reputation of its ancestors and is a fit memorial to its noted author. Notable improvements over the previous editions are found in the chapters on coal and coke, asphalt and paving materials, coal tar and derived oils, and gas analysis.

The work is planned primarily for the use of analytical and testing laboratories, for which it is invaluable. Although containing only 760 pages, it gives in excellent form methods for testing many of the common engineering materials. In addition to the chapters mentioned above, it includes methods for iron and steel, alloys, cements, building materials, oils, lubricants, soaps, paints, paper, and water for industrial purposes.

The general treatment of the various subjects may well be illustrated by the chapter on coal and coke. In this chapter there is given, first, in brief form, the technical methods of analysis and, then, in more detail, alternative and more exact methods. After this there follow notes and comments on the analytical methods, forms for reporting the analyses and tests, and, finally, specifications of large consumers of the various kinds of coal or coke. The determination of calorific value is described in a most satisfactory manner.

In the chapters on alloys and on oils and lubricants, Dr. Stillman has collected a great deal of information which it would be difficult to equal in another work of the same size. These chapters will be appreciated especially by those engineers who have been confronted, for example, with the necessity of determining quickly the composition of a sample of white metal or of detecting the presence of grease in a lubricant which has been found unsatisfactory.

The description of asphalt and pavement materials, and their physical and chemical examination, has been so expanded as to make this a chapter of great interest to municipal laboratories and highway engineers. The various asphalts and mixtures, methods for the examination of bituminous road materials, and the essential constituents for road construction and maintenance are discussed in considerable detail.

Since the book is of most value as a manual for the laboratory, it is not surprising that the author has found impossible the inclusion of lengthy theoretical discussions. Usually, only sufficient general descriptive matter is given to familiarize the chemist with those properties which are dependent upon compositions or conditions which may be tested for in the laboratory. While the effect of various ingredients on the hardness and other physical properties of iron or steel is stated clearly, we have found no mention of the different modifications of ferrite.

On the whole, the publication is a most valuable one and one which should be available to every chemist or engineer interested in analytical or testing work.

Charles L. Reese.

Steam Boilers

Steam-Boilers. By H. de B. Parsons, B.S., M.E., Consulting Engineer, Member of the Am.Soc.M.E., A.S.C.E., Soc. Naval Architects and Marine Engineers, etc. Longmans, Green & Co., New York, 1917. Cloth, 6 x 9 in., xvii + 377 pp., 157 illustrations. $4 net.

This book was written by a former professor of engineering and now a prominent consulting engineer in New York at first as a series of lectures to his pupils, and later, by certain changes, as a general book on boilers and collateral matters, such as the chemistry of combustion, fuels, boiler fittings, chimneys and other means of creating draft, smoke prevention, boiler coverings, etc. The first edition appeared in 1903, and the edition under review in 1917. Its purpose is to give its readers some general ideas concerning the matters mentioned above and of features of construction of the various common types of fire-tube boilers. Of water-tube boilers there is very little said, "because the manufacturers of such boilers issue complete illustrated descriptions and dimension sheets."

The author's aim is apparently not to go far beyond generalities, although he has evidently looked closely into details of construction, etc., and in them is well versed. He has succeeded well, and while designers of boilers seldom look into books, except the A.S.M.E. and similar Codes, young men will find the book very helpful, and any one interested in the subject of boilers will find it a good book to possess. In some respects the book is not up to date, as will appear below.

The diagrams were evidently prepared for this book, and it is gratifying that they are not taken from trade catalogues.

The book is what I suppose would be called "analytical," rather elementary, but sufficiently advanced for most purposes, and the illustrative examples are well worked out. The material is original as far as practicable in treating such a well-worn subject.

The early pages of the book are devoted to temperatures, specific heat, latent heat, factor of evaporation, combustion, cause and prevention of smoke, methods of firing, kinds of fuel, and definitions of fuel, combustible and efficiency.

I observe that the statement is made, as it is by many persons besides the author, that a large combustion volume is necessary for good results. I never accepted this dictum fully, for I have found that corrugated-furnace and locomotive-type boilers give as good gas analyses as others.

Chapter V begins with a general definition of boilers, and the distinction is made between "boilers" and "generators," the former being the fire-tube types and the latter the more modern devices for containing water in tubes and drums. Here, and in several other places, the author states that the "generators" contain less water than the "boilers" in proportion to their relative horsepowers. If the author should compute some of these volumes he might modify these statements. While speaking of the two types, the author calls them, except here and there, "fire tubular" and "water tubular" instead of the more common fire-tube and water-tube.

In discussing the rating of boilers I think the author attaches undue importance to the arrangements of surfaces.

the tops of tube plates of boilers not being very effective heating surface, but I have always considered such plates of fire tube boilers near the firebox as immensely effective.

I have stated that in some particulars the book is not up to date. Among the reasons for this statement are the engraving of the end of a cylindrical boiler which is made in four sections and a central patch instead of a head in one piece; a view of a horizontal return tubular boiler (Figs. 11 and 12) with both heads flanged in, which violates the principle which he lays down elsewhere that heads should be so placed that all joints can be riveted by a machine; the view of a vertical boiler (Fig. 15) which has a brick ashpit, and a cast-iron plate under the base or mud ring, both of which prevent calking the lower joints without raising the boiler; a fire-door opening formed in part by the mud ring and the remainder by a forged ring solid with it; the reversed flange wide and flat, both of which have caused disaster in many cases; and a form of smoke box covering which leaks air to a serious extent. Present-day construction employs a cast-iron ashpit which, at the top, is narrower than the mud ring and thus permits the bottom joints to be calked without removing anything. It also forms fire-door openings by flanging the plates and permitting the water to surround the opening. It is well to mention these things because the young engineer may feel justified in copying designs shown in a book by a prominent author.

It would have been well in discussing the submerged-tube-plate vertical boiler (Fig. 14) to have called attention to the complicated nature of the stresses in the upper tube plate and cone, the bending of the former when subjected to the test pressure, and the best manner of staying the cone. It may be well to call attention to the depth and double riveting of the mud ring in this figure, both of which are never employed except in some very large boilers, and then probably without sufficient reason.

A curious error in detail of boiler construction is given in Fig. 13, p. 81, in which the lower tube plate of a vertical boiler is flanged outside of the firebox inner plate.

In describing the different methods of supporting boilers it would have been well to have dwelt upon the importance of supporting all shell boilers at two points in the length, and mentioned that any such boiler regarded as a girder, is subjected to only an insignificant stress from its weight if supported only at the ends. Mr. Woolson's elegant three-point method is described but insufficiently praised. The method of supporting Lancashire boilers is that generally used, viz., by employing several supporting cradles; but even that boiler, long as it is, should rest on only two points. This method is employed in the Galloway boiler shown in Fig. 19.

There is very little to be said concerning matter relating to marine boilers as that is orthodox, but it would have been well to mention the great diameters, great thicknesses of plates, and high pressures employed at the present time, as for instance on the *Aquitania* and the new *Britannic*—recently sunk.

Reference is made several times to good steaming boilers, but to me it has always seemed as if a good steaming boiler is one that is large for its work, or that has a very strong draft.

The chapter on chimney draft is useful, but it would have been more logical to place it in another part of the book rather than between the descriptions of boilers and the materials of their construction.

The chapter on Materials is good and the A.S.M.E. Code is here made use of. In this chapter it is stated that "Many boilers have been exploded by permitting water to collect on top of cast iron stop valves." Is it possible that this is true?

In the chapter on Boiler Details the use of the elastic limit instead of the ultimate strength of plate in determining the thickness is advocated, which is, of course, correct. The late Mr. Leavitt is the only engineer that I have ever known to use this method. The boiler braces shown on pp. 200-201 have the usual defects of being able to straighten out where bent, and bringing most of the stress on one rivet.

The matter relating to riveted joints is deficient in illustrating a defective and obsolete type of joint in Fig. 75, and in not pointing out the defect of the prevailing type of butt joint used in this country, viz., that of having a narrow strap on one side of the joint and a wide one on the other. The defect is that the joint is non-central resisting, and therefore one which bends under stress, causes the plate to crack, and is likely to cause explosions. Tests of joints and experience show this. Nor is the advantage of butt joints with the straps of equal widths and all rivets in double shear in doing away with these defects mentioned.

It is gratifying to see that drilling holes from the solid is advocated, and I feel that this and the use of butt joints with all rivets in double shear are sure to be features of American boiler practice in the near future.

I am glad to see that the author condemns domes on stationary boilers as being useless and sources of weakness. I should advocate condemning brazed copper steam pipes, as they have caused several severe explosions.

Under the head of Boiler Fittings the down-draft grate is described and it is stated that for grates of equal area the capacity of a down-draft grate is greater than that of an up-draft. This is doubtful, inasmuch as in the latter the fire is drawn away from the fresh coal, and not through it.

The chapter on Mechanical Stokers is seriously defective because it gives nothing about the widely used underfed stokers known as the Taylor, Riley, Westinghouse, Combustion Engineering Co's. Type *E*, and Jones, nor any illustrations of chain grates which are so efficient in burning the western high volatile coals. Neither does it mention pulverized coal sufficiently, which has so recently become prominent and bids fair to be of immense importance to the railroads in utilizing the poorest coals and lignite, and in maintaining steady steam pressure.

The matter on Artificial Draft, Incrustation, Corrosion, General Wear and Tear, and Explosions does not call for special mention, but it is gratifying that a book now states that "Explosions occur when the steam pressure exceeds the restisting strength of the metal structure," instead of attributing them to mysterious causes.

Other matter relating to Chimney Design, Smoke Prevention, Testing Boilers, Boiler Trials, Boiler Coverings, Care of Boilers, and Superheaters is good.

F. W. DEAN.

Stresses in Wire-Wrapped Guns and in Gun Carriages. By Lieut.-Col. Colden L'H. Ruggles. John Wiley & Sons, Inc., New York, 1916. Cloth, 6 x 9 in, 259 pp., 94 illustrations. $3.

This work, which explains a number of the important engineering principles underlying the design of wire-wrapped guns and of gun carriages, was originally prepared for the use of the cadets of the U. S. Military Academy. Its chapters deal successively with elastic strength of wire-wrapped guns; determination of the forces brought upon the principal parts of the 3-inch field carriage and a disappearing gun carriage by the discharge of the gun; stresses in parts of gun carriages; toothed gearing; counter recoil springs.

MOBILIZATION

Mobilization consists in making all the resources of the country available.

The membership of The American Society of Mechanical Engineers possesses great resources of specialists in all branches of the profession of mechanical engineering.

Anticipating a large increase in demands for men, President Hollis appointed a Committee on Engineering Resources to carry out the work of immediately classifying all the members of the Society according to their capabilities for service. This Committee prepared a Professional Classification Sheet which has been distributed to the membership of the Society and from which 3,000 returns have been received to date.

The Council urges those who have not done so to give immediate attention to filling out their blanks and returning them.

Some members have replied that they have already filled out similar blanks for other organizations. While appreciating this the Council nevertheless hopes that every member will respond to this call.

No definite channel for mobilization of the engineers of the nation has yet been established, but undoubtedly the existing professional organizations will be availed of as they already have shown their capacity in the Industrial Census, and all agencies will be made to fit in with some official plan.

By the time that all returns from our members are received, the Committee on Engineering Resources hopes to have proceeded so far with classifying the replies, that it will have the means of supplying not only a particular man to fill a peculiar position, but to furnish the best man for that position.

General Information Regarding Presentation of Papers

THE American Society of Mechanical Engineers solicits original papers upon subjects of mechanical-engineering interest for presentation and discussion at its forthcoming Annual Meeting to be held in New York City, December, 1917, and also at its Spring Meeting to be held in Worcester, Mass., May, 1918. The manuscripts of such papers should be submitted to the Secretary, 29 West 39th Street, New York City, who will refer them to the Committee on Meetings for consideration.

Papers for presentation and discussion at meetings of Sections of the Society, which are organized in 21 cities throughout the country and which hold meetings monthly from September to May, are also solicited by the Society. Correspondence regarding Sections papers should be addressed to the respective Sections chairmen as follows:

Atlanta, Ga....Oscar Elsas, Fulton Bag & Cotton Mills

Baltimore, Md...W. W. Varney, 1221 Calvert Building

Birmingham, Ala...J. H. Klinck, 1146 Brown-Marx Building

Boston, Mass...A. L. Williston, 27 Kilsyth Rd., Brookline

Buffalo, N. Y...David Bell, 911 Lafayette Ave.

Chicago, Ill.....Alexander D. Bailey, 21 Elmwood Ave., La Grange

Cincinnati, O...Fred A. Geier, Cincinnati Milling Machine Co.

Detroit, Mich...G. W. Bissel, Michigan Agricultural College, E. Lansing

Erie, Pa........J. F. Wadsworth, 310 Commerce Building

*Indianapolis, Ind.*W. H. Insley, Insley Manufacturing Company

*Los Angeles, Cal.*Francis G. Pease, Mt. Wilson Solar Observatory, Pasadena

*Milwaukee, Wis.*Edward Hutchens, Federal Rubber Company, Cudahy

Minnesota, Minn. Edward A. Wilhelm, 1049 Van Slyke Ave., St. Paul

New Haven, Conn...H. B. Sargent, 247 Church Street

New Orleans, La...H. L. Hutson, 721 Lowerline Street

New York, N. Y...J. J. Swan. 29 West 39th St.

Ontario, Can...G. V. Ahara, 864 Dovecourt Rd.,Toronto

Philadelphia, Pa. Lewis F. Moody, 408 W. Chelten Ave., Germantown

Providence. R. I...J. A. Brooks, Brown University

San Francisco, Cal...B. F. Raber, 2027 Delaware St., Berkeley

St. Louis, Mo...R. L. Radcliffe, 701 Laclede Gas Bldg.

*Worcester, Mass.*George I. Rockwood, 33 Harlow Street

All papers accepted for a general meeting are printed in pamphlet form in advance of the meeting and are available to the membership of the Society. Also, comprehensive abstracts of the papers are printed in the monthly Journal in advance of the meeting.

After presentation and discussion, the revised papers are printed in the Transactions of The American Society of Mechanical Engineers, issued annually.

All papers presented at Section meetings are considered by the Publication Committee for publication in The Journal. The most meritorious Section papers are also assigned to general meetings and may be printed in the Transactions.

Authors of accepted papers receive twenty specially-bound copies with the compliments of the Society. Arrangements for the purchase of reprints at nominal price both from The Journal, size 9 in. x 12 in., and from the Transactions, size 6 in. x 9 in., can also be made through the Secretary.

Cincinnati Executive Committee, in Charge of the Spring Meeting, 1917

George Langen

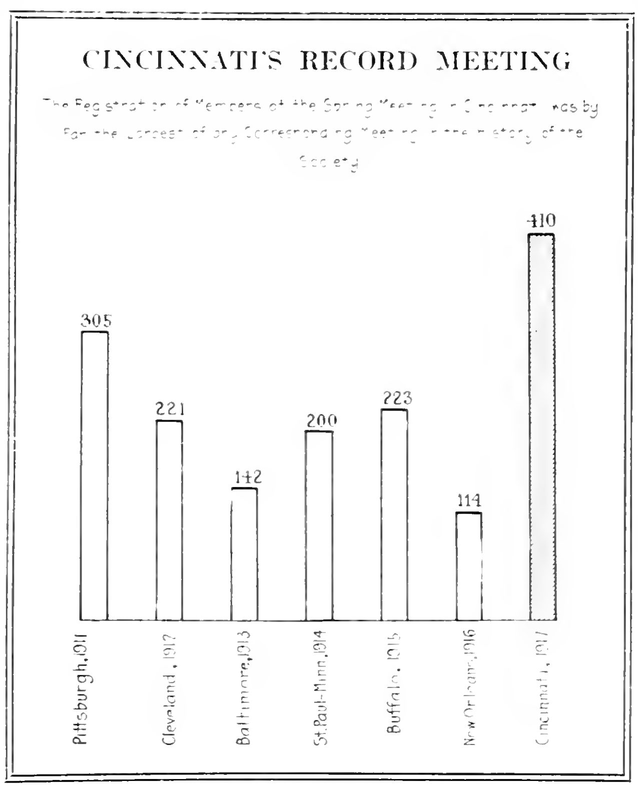
THE SPRING MEETING

WHILE not exactly logical to begin an account of the 1917 Spring Meeting in Cincinnati with a statement of the resolutions made in favor of the Cincinnati Local Committee at the close of the meeting, these resolutions so adequately express the sentiment of the gathering that perhaps the illogic may be excused. The resolutions follow:

WHEREAS, The American Society of Mechanical Engineers, assembled in convention May 21 to 24, 1917, at Cincinnati, Ohio has received a most cordial and spontaneous welcome from the members and friends of the Society in Cincinnati and vicinity: and has enjoyed the splendid coöperation and support of the local committees, through their tireless efforts on behalf of the Society, and their faultless preparation for the meeting, without which a convention of so marked a degree of excellence would have been impossible; and

WHEREAS, The visiting members and guests have been the recipients of a remarkably diversified and delightful entertainment bountifully provided on every occasion, and have had the opportunity to view many of the industrial wonders and other notable attractions of this remarkable center;

BE IT RESOLVED, That on behalf of the Society and of the visiting members and guests, a vote of thanks be extended to all who have participated in these substantial evidences of friendship and goodwill, with the assurance that such a formal resolution is but a poor and outward symbol of the deep sense of gratitude which each visitor personally feels. Further, that the Secretary be instructed to extend the thanks and appreciation of the Society, by written letter, to the local Executive Committee and the other local committees.



Those who were so fortunate as to be able to attend the meeting will testify that these resolutions are in nowise overdrawn. The Society did receive a most cordial and spontaneous welcome, the visiting members and guests being the recipients of a delightful entertainment. Evidences of goodwill were many, and the meeting was a complete success both from a professional and social point of view.

The headquarters was at the Hotel Sinton, and the total registration at the convention was 868, of which 410 were members and 458 guests. This was by far the largest attendance at any Spring Meeting the Society has yet held. The registration of members at the last six spring meetings is strikingly compared on the chart on this page, and shows the Cincinnati attendance far and away in the lead, in spite of the present national emergency exercising great restrictions on the time of professional men.

The exceptional attendance was no doubt largely attributable to the inclusion of sessions on munitions manufacture in the professional program. So many mechanical engineers and manufacturers throughout the country are expecting shortly to concentrate their whole efforts upon munitions work, and so many took advantage of the exceptional opportunity offered to benefit by the experience of those who have been devoting their energies to this class of work for nearly three years.

Another contributing factor to the large attendance was the holding of a joint session with the National Machine Tool Builders' Association. This is the first time such a session has ever been held. The presence of the Machine Tool Builders in convention at the same headquarters and at the same time as the Society contributed no small part to the success of our meeting.

The remarkable success of the Spring Meeting in all its features, however, must be directly attributed to the broad vision of the Cincinnati Committee, the systematic way in which its plans were laid, and the untiring efforts of its members in the execution of these plans. The members of the Executive Committee for The American Society of Mechanical Engineers were F. A. Geier, Chairman; G. W. Galbraith, J. T. Faig, W. G. Franz and George Langer; and for the National Machine Tool Builders' Association, J. B. Doan, Chairman; A. H. Teuchter, F. A. Geier, C. Wood Walter. A large number of sub-committees were appointed, all of which deserve the greatest credit for the perfection of detail in the conduct of the meeting. The Entertainment Committee, consisting of H. M. Norris, Chairman; A. J. Baker and A. A. Thayer, were constantly on the alert to see that no act should be omitted which would contribute to the pleasure of the guests. An account of the various entertainments will be found in the Society Affairs Section of this issue.

The social events began with an informal reception on Monday evening in the ballroom of the Sinton, with an address of welcome by the Mayor of Cincinnati and reply by President Hollis, followed by stereopticon views and dancing. The big social event for the members was the smoker on Tuesday evening, at which they were patriotically greeted at the Business Men's Club by the "Spirit of '76," and conducted to the assembly hall transformed to represent Losantiville, the Cincinnati of pioneer days, but modernized by brilliant kaleidoscopic lights. The evening's entertainment consisted of no less than eighteen numbers, concluding with the very gracious presentation by the Local Committee of a choice piece of Rookwood pottery to President Hollis.

The delightful boat ride on the river, the reception at the Country Club and the excursions to various institutions of the city and many of the modern manufacturing plants, all were greatly enjoyed. Further, Cincinnati's two dramatic

which both contributed entertainment which will long remain in the memory of those who were so fortunate as to witness their performances.

The professional program arranged for seven professional sessions: two munition sessions, one machine shop session, one gas power session, one industrial-safety session, one general session, and one joint session with the National Machine Tool Builders' Association. On account of the lively interest developed in the munitions sessions, these were ultimately expanded into three sessions.

The joint session with the National Machine Tool Builders' Association was a noteworthy event arranged by the Local Committees to show the consideration which is being given in Cincinnati to the humanitarian side of engineering. The addresses were by Dean Herman Schneider, the exponent of the cooperative system of education so successfully developed at the University of Cincinnati; and by Dr. Otto P. Geier, medical director of the Cincinnati Milling Machine Company, dealing with the work of the socially minded physician in industry. Both addresses touched a high plane and were an inspiration to the audience which filled the large ballroom of the Hotel Sinton. This joint session was followed by a timely motion picture exhibition, arranged by *Machinery*, showing the processes of manufacture of 9.2-in. shells.

As usual at the Spring Meeting, the sections of the Society, through their representatives, showed themselves to be very much alive, and enthusiastic conferences were held at which there were members in attendance from eighteen different cities.

The Cincinnati Committee prepared a complete program of the professional and entertainment features for our own Society and for the National Machine Tool Builders' Association.

In what follows is given a running account of the professional sessions with abstracts of such parts of the discussion as it is believed will be of greatest interest to the membership, while additional notes will be found in the Society Affairs Section. The professional papers have already appeared in the May issue of The Journal.

MACHINE SHOP SESSION, TUESDAY MORNING

The Machine Shop Session was called to order by Howard P. Fairfield, Secretary of the Sub-Committee on Machine Shop Practice, for the presentation and discussion of three important papers: A Foundation for Machine Tool Design and Construction, by A. L. De Leeuw; Machine Shop Organization, by Fred G. Kent, and Metal Planers and Methods of Production, by Charles Meier.

The session was well attended, a number of the recognized authorities on machine-tool design, construction and operation being in the audience, as well as many of the prominent machine-tool builders in Cincinnati, and the discussion was very representative and brought out many points of value.

As was anticipated, Mr. De Leeuw's paper in particular, embodying a questionnaire upon matters which should be settled before the design of machine tools can proceed in a thoroughly scientific manner, brought out the largest volume of discussion of the three papers and occupied most of the session.

MR. DE LEEUW EMPHASIZES THE NEED FOR RESEARCH IN CUTTING METALS

In presenting his paper, A. L. De Leeuw said that in it he tried to call attention to the fact that one of our biggest industries, the machine-tool industry, was not based on scientific principles, and yet it seemed that a scientific foundation would be perfectly possible. All the branches and all the phenomena of the cutting of metals could be reduced to mathematics, and this paper called attention to the fact that no branch of engineering progressed with any rapidity or certainty unless its facts and data were reduced to mathematics. Perhaps one of the reasons why the cutting of metals had not progressed along scientific lines was because it had been done for so long and by so many people.

The author further pointed out that the foundation for the design and construction of machine tools would probably lead to very important results. Some action should be taken toward the establishing of this foundation, and he hoped it might be taken under the auspices of the Society.

What was immediately needed was a research into the functions and actions of the cutting tool, the action of the cutting lubricant, etc. Experiments already made by him were outlined in the paper, and suggested lines of further experimentation were indicated.

The paper was discussed by Albert Kingsbury, H. Wade Hibbard, R. Poliakoff, A. Lewis Jenkins, Leon P. Alford, Frederick A. Waldron, Carl G. Barth, Arthur J. Baker, Charles Fair, Luther D. Burlingame, Ralph E. Flanders and Richard T. Wingo.

Albert Kingsbury contributed a written discussion of the action of lubricants on metal-cutting tools, in which he said that it was very well known that a proper lubricant applied to tools when cutting tough metals improved the cutting, but it was not obvious how the lubricant acted, since the cutting edge of the tool was apparently buried in the metal, and therefore it was not readily seen how the lubricant could reach the cutting edge.

He had made an experimental study of this question about the year 1895. A mild-steel bar was mounted in a lathe, held by chuck and center rest, and was cut by a parting tool with one side flush with the end of the bar. A microscope magnifying about 30 diameters was placed for examination of the chip during formation. The bar was rotated very slowly by using the back gear and pulling the belt by hand.

Figs. 1, 2 and 3 showed roughly successive stages of formation of the chip. The most important phenomenon was the fact that a crack in the metal preceded the cutting edge of the tool at all times. The crack began at the point C in Fig. 1; it extended in substantially the direction of the finished surface of the work, as in Fig. 2, up to a certain point where it suddenly turned outward about 45 deg. as in Fig. 3.[1] This action was cyclical, beginning again when the point C reached the cutting edge. The successive surfaces of these cracks formed the finished surface of the work, if the tool was sharp, thus giving the well-known cross-banded appearance of the tool marks; but if the tool was dull there was more or less rubbing of the tool over the surface after the cracks were formed, altering the appearance of the surface very noticeably. Oil being applied to the work, as the crack extended the oil was seen to flow into the crack, the flow being made evident by the motion of minute particles of steel suspended in the oil.

[1] Similar descriptions of the formation of the chip are given in Trans. Am.Soc.M.E., vol. 28, p. 75 and p. 333.

Thus the oil was enabled to reach the top surface of the tool, even to the cutting edge. The principal effect of the lubricant appeared to lie in the reduction of friction on the top face of the tool; this increased the frequency of the cyclical breaking of the chip, shortened the chip segments and reduced the length of the cracks in advance of the cutting edge, and thus made the finished surface smoother.

This phenomenon explained several facts regarding the lubrication of cutting tools, well known to machinists, as follows:

a Good lubricants of rather high viscosity, such as lard oil, were very effective when the cutting speed was slow, as in tapping and reaming by hand, but if the cutting speed was high, as in high-speed milling and drilling, lubricants of very low viscosity, such as soda water or soap and oil emulsions, were more effective. The lubricant was forced into the vacuum in the crack mainly by atmospheric pressure (capillarity probably being secondary if the cutting speed was high). Therefore, if the viscosity of the lubricant was high the cracks might not be filled fast enough.

Fig. 1 Fig. 2 Fig. 3

Figs. 1 to 3 Successive Stages in Formation of Chip

b In the case of a parting tool cutting off a bar, the tool lubricated well at the beginning of the cut, but not when the cut became deeper. In the deep cut the chip was "upset" and filled the slot, and therefore the lubricant could not readily enter the cracks from the sides of the cut. It had been found efficacious, in large work, therefore, to use two tools simultaneously in parting or slotting cuts, the leading tool being narrower than the following tool; thus both tools were fairly lubricated, the leading tool from both edges, and the following tool from one edge of each of its two narrow chips.

c In finishing cuts with broad tools, the lubricant must penetrate the cracks for long distances; thus it was necessary to run slowly and to use thin lubricants such as kerosene or turpentine. More viscous lubricants might be used if the speed of cutting were exceedingly slow. There must be sufficient time for the lubricant to flow in the cracks from the edges to the center of the cut.

d In slab milling, etc., it was found advantageous to notch the cutting edges at frequent intervals; this broke the wide chips into narrow ones and thus favored the entrance of the lubricant.

e In general, the more viscous lubricants were used only for slow speeds or narrow cuts, the less viscous for higher speeds or wider cuts. Even a poor lubricant, if it flowed readily enough to penetrate the cracks rapidly, was more effective than a good lubricant which was too slow in getting to the spot where it might be effective.

H. Wade Hibbard said that, as in thermodynamics, the fundamental consideration in machine designing was the ultimate constituency of matter. In a piece of steel there were millions of atoms held in relation to each other by "springs"—forces of cohesion and repulsion. If this piece of steel were heated, the forces that tended to separate the atoms were increased; if cooled, these same forces were diminished. To make a study of how to cut a piece of steel, one must consider what was being done with these "springs" connecting the atoms together.

All the forces applied to a piece of steel in cutting it, or in testing it, as Mr. De Leeuw had shown in his diagram of the tension test of a piece of steel, could be resolved into just two kinds of forces, the normal forces, plus or minus, and the tangential forces, either plain shear or rotating shear.

"Upon this theory of the ultimate constituency of matter, and the forces which hold atoms together," continued Professor Hibbard, "some of the things that puzzle us in machine-tool designing are made more clear. For example, the author asks, 'When we turn up a narrow disk by means of a square-nosed turning tool, of which the width is greater than the width of the disk, is the action of removing the chip purely a matter of tension? Or, if not, what is it?' No, it is not purely a matter of tension, because according to the above reasoning both normal and tangential forces are acting on the 'springs' holding the atoms together. Also, 'What is the nature of the lamination of the chip?' Its nature is almost purely the action of the tangential force upon those 'springs' holding two adjacent layers of atoms together.

"'We do not see at the present time how it is possible for the lubricant to influence the size, yet that it does do this has been observed a great many times,' the author states later. That, I believe, if we think of these two kinds of forces, the normal and the tangential, means that by lubricating the top of the tool we reduce the normal force, necessarily. In other words, we reduce the compression of the chip in the direction of the length of the chip, and that, of course, has its effect upon the size of the turned part which is left, after the part has been turned by the tool."

R. Poliakoff[1] said that in Par. 32 the author referred to a tool which was shown in Fig. 4, and observed that that tool after it had been used began to show scratches. Now, he did not know what was the plan of the tool, whether it had a round edge or not, but, if so, the scratches might be attributed to the fact that in leaving the work internal friction was developed among the elements of the chips, which caused them to rotate, one against another, and in this way to scratch the tool. He had started some experiments along this line, but had to abandon them when he came to the United States, but he hoped sometime to continue them. It would be better, perhaps, just to drill out the top of the tool, instead of making it flat, which would give a better tool, and also one that would take less power.

Regarding the circular tool, described in Par. 35, he believed Mr. De Leeuw originated that tool some two and a half years ago. He did not know how much experimenting had been done on the tool in this country, but as soon as he had read about it he had made one on the same lines, and wanted to experiment with it, but, unfortunately, was obliged to go away. However, in a remote factory in the Ural Mountains they did make a tool similar to that shown by Mr. De Leeuw, and they found that it gave them a great saving.

He thoroughly agreed with what the author said under the head of "Suggested Lines of Experimentation," but could easily see some objections from the so-called practical viewpoint—from the point of view of the practical shop man.

[1] Technical Institute of Moscow, Russia.

As Mr. De Leeuw suggested, if such low feeds were taken, the ordinary shop man would say, "that's all right." It might be all right in theory, but how about the practice. Perhaps the practical conditions would be quite different. In connection with this, he wanted to mention that very little in the way of experimental data had been published along these lines of cutting, especially as compared with the ordinary shop practice. Edward Herbert, however, had been working along these same lines for some time, had published some results which were very interesting with reference to the finishing cut, and had shown that the tool failed in a different way from what it did on the ordinary roughing cuts. When Mr. Herbert presented his valuable paper on this subject about four years ago, he had to encounter this same objection of impracticability on the part of the shop man. In order to meet this objection to a certain extent, Professor Poliakoff started some experiments on the finishing tool from the practical view of the shop man, and under the ordinary shop conditions, and had found that the result of his experiments exactly corresponded with Mr. Herbert's under ordinary conditions of speed. These results were printed in a paper about two years ago.

In Par. 30, it was stated by the author that the results should be in the direction of the saving of power. As to this, he would say that a Russian professor, Mr. Simon, had experimented along these lines, and published the results of his investigations about three or four years ago; they showed, or tended to show, that with different lubricants the consumption of power was different, other conditions being the same. While a saving in power might not always be necessary, yet by diminishing the power required, the strain on the machine would be decreased. So that the investigation of the lubricants used in cutting was naturally of very great importance.[1]

A. Lewis Jenkins said that, at the suggestion of Mr. De Leeuw, about three years ago a set of stationary cup-shaped lathe tools, similar to the tools shown in Fig 6 in the paper, was made at the University of Cincinnati. Something like 600 tests were made to compare the power required for the De Leeuw tool, as they called it, with a standard Taylor tool made by the O. K. Tool Company.

The cutting angles were varied from 16 to 90 deg.; the diameters of the tools were varied from 1.25 to 1.4 in., and the work specimen was a piece of steel 4 in. in diameter and 30 in. long. The machine employed was the LeBlond 21-in. all-geared-head lathe.

The tests were made by using a cradle dynamometer, and after taking the readings for one tool at a given feed, depth and speed it was removed and the other tool put in place without changing the speed, feed and depth of cut. The conditions of operation were therefore exactly the same for both tools.

The De Leeuw tool gave a higher finish than the Taylor tool. The De Leeuw tool made no chatter marks when the work was greater than 2 in. in diameter and the cutting angle less than about 80 deg., even on the heaviest cuts taken. The Taylor tool chattered on all diameters when taking the heaviest cuts. The results of these tests showed that a De Leeuw tool having a 40 deg. lip angle required about 90 per cent of the power required to drive a Taylor tool under the same conditions. For cutting angles greater than 60 deg. there was practically no difference in the power required for the two types of tools when operated under these conditions. The feeds varied from 1-64 in. to 1/8 in. and the depth of cut varied from 1-32 in. to 1/8 in.

Leon P. Alford said that a recent question before the Research Committee of the Society was: "What can this Committee do at the present time which might have a beneficial effect in helping this country at war?" One of the sub-committees brought in the suggestion that very little had been done in the direction of a study of the action of cutting tools and the cause of chip formation, and it was decided to concentrate the efforts of the Committee upon that topic. As a member of the Research Committee, he would like to ask Professor Jenkins if he would place in the Committee's possession all the information he had in regard to the series of tests described, and also if Professor Poliakoff would do the same thing in regard to the investigation he had made and from his experience with this tool in the Russian rifle works.

Richard T. Wingo thought that one of the things the Society could do to advantage was to organize the machine-tool shops, with a view to exchanging information regarding tool equipment and methods. His reason for saying that was that it would be found, in going into one machine-tool shop, that it was doing a certain thing in a certain way, but if a competitor came along, very frequently it would be found that that shop was under lock and key because it did not want to show a competitor how it was doing its work.

Of all the branches in mechanical lines, the automobile had brought about the most remarkable results, and it had been done by one concern showing another what it had been doing in every detail.

Frederick A. Waldron thought that in all this work there was a sort of eternal fitness of things, which should lead us to begin, if possible, with a classification of machine tools. This should be confined to machine tools in general, so as to cover the paper now presented.

The classification took the following form in his mind: *first*, machines of convenience; *second*, machines of precision; and *third*, machines of displacement. The machine of convenience was one principally for a jobbing shop not having too heavy work, in which the convenience of the operator, the interchangeability of face plates, of centers, gears, feeds, etc., was paramount. Machines of precision were designed principally for use in tool-room work and on work requiring the greatest precision. Machines of displacement were intended to remove large quantities of metal in the minimum time, with the maximum life of the tool and with the maximum life of the machine.

Carl G. Barth said that he was delighted with the manner in which Mr. De Leeuw had pointed out the part that mathematics played in the development of engineering, for there were as yet too many among those who practiced engineering who were sadly lacking in the everyday recognition of that fact.

However, he believed that, when it came to the art of cutting metals, we already had at our command a wealth of information that should be made more generally available and applicable in everyday machine design and machine-shop practice before we undertook to spend money and efforts in further experiments and investigations, even along the undoubtedly fundamentally sound and interesting lines suggested by Mr. De Leeuw, which at the same time did not promise enough in early results that might be immediately applied to increase the production of the present machine-tool equipment of the country through the present workers and their foreman.

[1] The above notes convey the purport of Professor Poliakoff's remarks. His full discussion, with illustrations will be published later.

Having for some fifteen years made it his principal specialty to increase the production of machine shops, he had, after all, found that the greatest difficulty in the way of increased efficiency was that of educating workers and their foremen to see the fundamental principles underlying their work.

In his judgment, the Society could do more immediate good by appointing a committee to gather together and formulate the knowledge now available, and then perhaps supplement this by further experiments with the various forms of cutting tools already in use; this committee finally instituting a regular campaign of education of the metal workers of the country to utilize the information compiled.

Personally, he stood ready to coöperate with such a committee and to give up the information he had, and to divulge the means he had from time to time devised to make this readily applicable in practice.

When he offered this counter suggestion to Mr. De Leeuw's proposition, it was merely as a practical expedient to obtain results quicker, for he was sure that he believed fully as much in getting to the bottom of things as did any other member of the Society, Mr. De Leeuw not excepted.

He had received his principal training through his coöperation with Dr. Taylor, and the latter had always said that it was better to concentrate on making use of whatever useful facts we had than to spend time on ascertaining even better facts.

Arthur J. Baker, referring to the type of turning tool shown in Fig. 4 of the paper, said that about eighteen years ago, in England, his firm was making tools for turning shackle pins for the Admiralty. These were large tapering pins, say, two or three inches in diameter at the small end, and running up from six to twelve inches in length, and were turned on rather large lathes. When they used the standard type of tool, the machine would not take the cut at a feed sufficient to enable them to produce the pieces in the time that they felt they should be produced in; so they slowed the machine down, but failed to reduce the feed. They then made a flat-topped form tool for the roughing operation, and sunk into its top surface a half-round cutter which left a flat lip or land about 1-32 in. wide on all of the cutting edges. This construction reduced the friction and enabled them to take a cut of almost twice the average that they were able to when using the standard type of cutter.

In regard to the circular turning tool shown in Fig. 9, he had been instrumental in placing a number of those tools in various lathe plants around the country. Some of the users employed them in experiments, and some, he rather thought, did not believe they were very practical and did not go further with them, but the Pennsylvania Railroad, at Altoona, used them on some of their larger rods, with quite satisfactory results, except for this one drawback: that the circular tool could not be used on any job where it was desired to cut up to the shoulder, because the retention of the rather thin cutting edge between the chip and the work usually caused a breaking as the tool was withdrawn. So that the real virtue of a tool of that kind was confined to its use on work that enabled one to pass quickly across the surface. The American Blower Company, of Detroit, had used one of these tools for turning pulleys, and the results were highly satisfactory indeed.

The cutting speed used in turning the Pennsylvania Railroad rods was about 65 ft. per min. They made no attempt to get high speeds. The cast-iron pulleys turned at the American Blower Company, in Detroit, were run approximately 130 ft. per min.—the iron was tolerably hard—which was the highest speed they had been able to use.

Luther D. Burlingame said he would like to offer a resolution, based on the idea that Mr. De Leeuw had brought forward a work of real importance and a work well worthy of attention, that the meeting urgently request the Council of the Society that suitable funds be put at the disposition of the Research Committee in order to carry on the experiments in regard to cutting tools, along the lines referred to in Mr. De Leeuw's paper.

Ralph E. Flanders asked whether it would be possible to secure the coöperation of Mr. Barth and his associates with the Research Committee, or any other proper committee that might be formed. It would seem to be possible, for instance, to put the information on lathe tools, speeds and feeds that was obtained by Mr. Taylor's work into some concise form so that it could be used by engineers anywhere in the machine shops of the country. It seemed to him that this would be a simple, direct and patriotic service that could be rendered to the country just at this time.

Charles Fair said that he agreed with Mr. De Leeuw that we would not get very far in our investigations so long as these investigations and tests were conducted by individuals in a more or less haphazard sort of way, and almost invariably by some short-cut method which usually resulted in not getting the necessary data that would make the tests of any value. It was too bad that more methodical consideration was not given to such investigations. He knew of no body more fitted to undertake this work than the A.S.M.E., and he would therefore like to suggest that this Society should carefully consider the subject with a view to the laying out, if possible, of some definite plan of action not only to be followed by the Society, but elastic enough so that it would be useful to the individual investigator who cared to coöperate with the Society. Much time was being wasted by a repetition of what might almost be called standard tests, while little thought was given to that which might seem to be secondary, but which, in reality, might be of great importance.

While he thought that some of the questions raised by Mr. De Leeuw might be satisfactorily answered, he was afraid that it would require considerable investigation before he would venture on even an intelligent guess as to the answers to a number of others.

CLOSURE BY MR. DE LEEUW

The author said, in closing, that Professor Hibbard had gone several steps further than he would want to go at the present time. We did not yet know very much about the ultimate constituency of matter.

In answer to Professor Poliakoff's question as to the shape of the tool that was used, he would say that this tool was of the square type, with a slightly rounded column and with an angle in both directions, and instead of the angle a groove was substituted in the direction of the feed. Most of the metal was not flying up tangentially to the direction of cutting, but it was flying off at right angles to the direction of the feed. The scratches were all in that direction.

There was no particular way in which the tool would fail: it would sometimes fail near the point, as if the tangential flow of metal would cause it, but more often it failed in the other direction. The importance of the scratches was simply that almost immediately after they began to form the tool would fail, showing, therefore, that the greatly increased friction over the surface of the tool caused the breaking down of

the tool probably on account of heat, and possibly on account of the increased force there.

Professor Pohakoff also mentioned that the idea of a very low speed would not appeal to the man in the shop. From what he knew about the man in the shop, he would not think that any experiment of that kind would appeal to him. The fact was, the man in the shop was not inclined to do experimenting and was very much opposed to it.

He was heartily in accord with Mr. Waldron's idea of a classification of machines. It was getting time that we should know what we were talking about. We were talking about machine tools, about a lathe, for instance, but a lathe might be used for so many different purposes. However, he believed that a very large portion of the work done by machine tools in modern industries was work of displacement. The lathe, as constructed at present, was utterly unfit for using a lighter tool. The conditions were so radically different that he did not believe the lathe could be used as it was at present. In the first place, a very much larger proportion of the power consumed had to go through the lead screw. In the second place, in order to get the best results the lathe should run at a very high speed. And, running at a high rate of speed with a bar perhaps five feet long, running 1350 revolutions, was a very dangerous proceeding. If the end should run off there would be some disaster. Furthermore, it was not possible to run the ordinary lathe at the speed required for that tool. One of the things to be done would be to arrange a lathe so that such a tool could be used to advantage. Still another thing: under those tests the carriage traveled 47 in. to the minute. Now, at that rate, it was not possible to throw out the feed by turning the knob; it was possible, but not within half an inch. In other words, if the left hand should fumble with that knob for just an instant—one second—it would run up against the operator's shoulder and there would be something doing! In regard to what was said about slide rules, that was really a matter that he did not wish to discuss; he did not wish to say whether a slide rule was going to improve the performance of the lathe or not; in fact, he knew it did, but that was a matter of management—a matter of the use of the knowledge we had at the present time. It was very far from his idea to suggest that we should not use the knowledge we had; his paper was not aiming at that at all. He neither advocated neglecting to use the knowledge we had, nor did he advocate its use. To advocate not using the knowledge we had would be a piece of foolishness, and to advocate using it would be almost an insult to the engineers present. What he was urging was to gather up knowledge. Whether it was practical at the present moment or not had nothing to do with the question. We all knew that before knowledge could be made practical, the knowledge must be available. There was no use in talking about the particular nature of the thing when we did not have the thing. The main thing that he would urge was that they should go forth and get it, and that they should try to find out some of the elementary knowledge about the art or science of cutting metals. Personally, he felt that when we had that knowledge we would be able to use it. The American nation had shone especially in the application of knowledge, but it had not shone in the gathering up of knowledge. He had no doubt whatever that there were a great many men in this country who were just as capable of finding and gathering up knowledge as there were abroad, but he believed that heretofore we had had the habit of looking at the mere gathering up of knowledge as something that had no particular value, but as merely a sort of a plaything for the professor who sat in his study and did his thinking and played with his thoughts, and then wrote it all down in a book and the book was put somewhere on a shelf in some library and was forgotten. But that should not be the case. Of all the knowledge that we gathered up, there might perhaps be a certain percentage that was not immediately usable, but he could not think of any great, or even fairly notable, discovery in science that had been made that wasn't at the present time employed in actual practice. If Professor Roentgen had first said, "Let me see what I can use X-rays for," and then, after he had made out what he could use them for, had said, "Now, let me see where that X-ray is—let me hunt it up"—we would have had no X-rays. If Professor Becquerel had first asked himself what he could do with those peculiar Becquerel rays, and how he could use them for transmitting knowledge from one end of the earth to the other, he never would have found the Becquerel rays; the Hertzian violet rays never would have been found, and we wouldn't have any violet rays at this time. Those simply gathered up the knowledge, and then there were other men who were, perhaps, working on different lines who took that knowledge and applied it. So that his plea was for definite knowledge. He had a profound belief in the ability of the American engineer to apply that knowledge after he had found it.

MR. KENT PRESENTS HIS PAPER ON MACHINE SHOP ORGANIZATION

In his paper on Machine Shop Organization, Mr. Kent outlined briefly the basic structure of an organization for a shop building the average line of machinery, applying his remarks to a shop employing 600 men or less.

It was the contention of Mr. Kent that the average shop should have the following departments: Works office, engineering department, pattern shop, tool design and storage, tool making and repair, plant engineering and power, machinery, and erection.

This paper was discussed by J. M. Spitzglass, Mark H. Landis, Elmer H. Neff and A. L. De Leeuw.

J. M. Spitzglass related an experience in shop organization or reorganization which was rather the opposite of the experience cited in the paper.

In this case, the shop was a very small one, having a few groups of two or three men in each group. The management of the shop was visibly incapable, the equipment poor, and the material, while not poor, was very poorly applied.

He could not be present there all the time at the beginning of the reorganization work, but he placed at the shop a very bright young man, in fact a genius in mathematics and system, to make a systematic study of the work and to help in the reorganization of the methods and workings in the shop.

During the first two months he had his hands full in keeping this young man back. He simply could not wait, but wanted to revolutionize, and, in fact, did revolutionize, many things from the very start.

Of course, friction arose from the first moment. The foreman of the shop openly objected to the various innovations. The men in the shop did not like them, though they seemed to be to their advantage, and Mr. Spitzglass, himself, had continuous missions on one side to pacify the shop, and on the other side to keep the young man back, and the latter was the harder job.

The author had pointed out that the time study and the bonus system should be considered only after all other leaks had been attended to. We should consider the fact that in the case of office reorganization we had to deal with men who

understood us at once. They were with us and helping in every way and, therefore, office reorganization was comparatively easy.

When it came to the time study of the men in the shop, we had to deal with individuals who were certainly not with us at the start. If they had anything against us they would not express themselves, and we were working in the dark, which was one more reason for taking sufficient time before the work of time study and bonus system could be started in the shop.

Mark H. Landis said that discussion of the question as to whether it was always right to arrange machines according to their function, led him to state an experience in his plant.

On the small parts—gears, shafts, etc., and the small parts in general that were put into the stock room—it seemed better to have those machines arranged in departments, according to their function, milling department, etc.; but, for the heavy castings, beds, turrets, etc., it seemed preferable to arrange those in departments, according to the castings themselves. In his shop, about a year or so ago, they made a diagram of the shop and all the machines, showing the path that the heavy castings followed through the shop, and it amazed him to see what a tangle of lines represented the moving of the heavy castings. Such a tangle was inevitable unless the shop was so arranged that the castings followed more or less straight lines.

Elmer H. Neff discussed the point that "the inspection department must be answerable to the works manager or his assistant only." One of the largest plants and perhaps the most successful in the country was organized on that basis many years ago, and he believed that that was one of the principal elements in the success of the plant, as he believed it would be in any case where it was consistently followed out. He wished to emphasize that point, because he believed it to be a very important one. There were shops in this country today in which the foremen were allowed to override the work of the inspector, and the results, according to his observation, were always disastrous.

Adolph L. De Leeuw did not believe that it was possible to arrange the machines in shops as Mr. Landis recommended. So many different factors entered in that he did not think it possible to make a general rule. If one had a shop small enough and with a small line of production, producing only comparatively few things, the plan was perfectly possible. If, on the other hand, in that shop they were making 250, or even only 25 different things, unless the output of each of the different classes of machines was very large, he thought such an arrangement would be impracticable, and that that shop would probably be arranged so as to have the larger parts follow the same route as the smaller parts.

If one went still further and took a shop where they made not 250 different varieties but 3000, there would be a reversion and the machines would be placed in groups.

He said that at the plant with which he was connected, there was one shop that assembled the machines, and there were others to furnish the parts. For example, one of the parts was so small that a dozen of them could be put in the vest pocket, yet there was a shop comprising perhaps twenty, thirty or forty machines, that did nothing else but make that part. And yet, even in that establishment they departed from that system again, because when it came to making sheet-steel pressed parts, which had to be handled in such a different way, if these parts had later on to be milled or drilled, or have some other process performed on them, the work was thrown back into the drill department because there the skill and knowledge required to get the best results in the process was such an absolutely individual thing that it would not pay to have the parts distributed over the entire shop.

Though the press parts all ought to be kept in the press shop, yet there were parts which required such particular knowledge of the function of that part after it was made, that it was better again to put the presses in the department where the part was made.

This was just exactly the condition that would be found in most shops. No general rule could be of any value unless a very careful study was made of the individual requirements of that shop and of the parts made in it. There were certain screws made in the screw department, but there were screws made in other departments, too, because there the important point was to understand the requirements of that particular screw; that was of greater importance than the making of the screw mechanically.

He would suggest that in discussing the arrangement of machines in the shop, we forget all about any general rule that might be presented, or that ever had been presented, and study the problem as we found it.

Carl G. Barth wrote that as Mr. Kent's paper read in the main as if it had been written by someone directly trained in the art of managing by Dr. Taylor, he most heartily agreed with nearly everything it contained. What the author said about leaving such matters as time studies and wage-payment schemes to the last, when reorganizing a shop, he believed in so fully that he wished it could be made a law in our statutes; for the introduction of these features of scientific management before the proper foundation for them had been laid was doing a great deal of harm around the country, particularly as only too often the men entrusted with that kind of work lacked the necessary knowledge and experience to do it properly at any time.

The ideal way of effecting a reorganization of a shop undoubtedly was, as Mr. Kent said, by putting a competent man at the head of the organization to do the work; but, unfortunately, there were not enough of that kind of men to go around, so that there was still a legitimate field for the professional outside reorganizer. Such a man should, however, as had now been his own practice for some ten years past, to the greatest possible extent do his work through someone in the permanent organization, whose education in modern management methods thus became his principal task.

In nearly all the shops that he had reorganized, the product had been of such a nature that his efforts had been to group similar machinery together; that is, adopt what might be termed the functional arrangement of the machines; but under certain conditions it would be absolutely preposterous to do this, and no hard and fast rule could be laid down in this matter. Each shop became properly a study of its own.

H. Wade Hibbard said, in criticism of Par. 5, that a wage-payment scheme was not necessarily involved in time study. Certainly time study should come early, preceded by analysis of an operation into its elements, then timing the elements. Often it was found that the company was itself the greatest time waster, and this waste could be eliminated without any reference to the wage-payment system.

CLOSURE BY MR. KENT

Fred G. Kent, in a written closure, said that the discussion seemed to make it necessary to reiterate what was said at the

beginning of the paper, namely, that this paper was confined to the treatment of an organization employing from 300 to 600 employees engaged in producing an average line of machinery.

A great deal of the discussion about the arrangement of machines according to classes or according to the pieces produced was very interesting, but was beside the point so far as this paper was concerned. However, it seemed to him that in a shop of any size, if its product was subject to any variation at all and to alteration of design, there was a fundamental principle which made possible a fairly general rule.

The most important factor in the grouping of machines was the need for getting the greatest skill obtainable in the organization applied to each operation. Skill of operation would far more than offset very considerable expense in the transportation of material which might result from the necessity of moving pieces even of considerable weight over considerable territory. In other words, the man in an organization who knew most about screw machines, should have all screw machines in his department and be responsible for all screw-machine work. The man who had made a specialty of planing and who treated it as his life work, would know far more about his job and would take far greater pains in his work than any man who had charge of the manufacture of one piece requiring many different machines other than the planer, and this man whose specialty was planing should therefore have charge of all the planers in the shop and be responsible for all planing work.

He had tried to show at various points in this paper, and wished again to emphasize the fact, that the most important factor to be dealt with in the shop organization was the human element. This factor was, of course, the least subject to the exact operation of formal rules. It was never long the same in any one shop and never the same in any two shops, and it was the most important thing to consider in the question of the time at which it was most advantageous to take up time study.

It was, of course, never amiss for the foreman of a department to study very carefully the efficiency of any of the operations carried on in his department, and to suggest and carry out changes, but the bringing into the department of some stranger, or a man whom the workmen looked upon as a stranger, to carry on a scientific analytical study of operations, was a thing to be taken up only after all obvious leaks were stopped and the confidence of the workmen firmly established. In fact, it was his belief that reorganization could be carried on with the greatest profit where the fact of reorganization was kept very thoroughly in the background and even not suspected by the average workman. It was true that conditions might sometimes be so bad that violent action was the only possible means of introducing a remedy, but in general it was safe to say that the best types of shop organization were like the best types of life everywhere: they were a matter of growth rather than revolution.

MR. MEIER PRESENTS HIS PAPER ON METAL PLANERS

The paper entitled Metal Planers and Methods of Production, by Charles Meier, presented by the author, described the evolution of the planing machine to provide the increased speeds and power to develop the possibilities of high-speed steel and to meet the increasing necessity for greater production. The paper also analyzed the operation of the planing machine and showed how, by improved methods of setting the work, measuring for rough cuts, fitting for finishing cuts and changing tools, the production of the machine could be greatly improved.

Mr. Meier's paper was discussed by Charles Fair and Carl G. Barth.

Carl G. Barth said that Mr. Meier's paper was interesting, as it was probably the first attempt in the way of a published statement of the actual gains obtained by the use of aluminum pulleys instead of cast-iron pulleys on belt-driven and belt reversing planers, as first done by the Cincinnati Planer Co. However, on investigating the experimental data set forth in the tables, he had found them far from consistent.

Frequently during the past seventeen years he had had to conduct similar experiments with planers of various kinds, in order to determine the length of time it took them to make any length of double stroke between a minimum and the maximum of each one, for the purpose of incorporating this information on his Planer Time Slide Rule, and in making such experiments he worked on the theory that the time consumed in stopping and reversing the planer table at the end of each stroke must be independent of the length of the stroke, and that it could hence be considered equal to the time it would take the table to travel an imaginary addition to its actual stroke, at its full forward and return speeds. Thus, if l designated the actual length of stroke, and a this imaginary or ideal addition, then the total time for a double stroke would be

$$t = \frac{l+a}{v} + \frac{l+a}{V} = \frac{V+v}{vV}(l+a) = C(l+a) \dots\dots [1]$$

v and V being respectively the forward and return speeds of the table.

Similarly, for $l = l_1$ and $t = t_1$,

$$t_1 = C(l_1 + a) \dots\dots\dots\dots\dots\dots [2]$$

and dividing [1] by [2] would give

$$a = \frac{tl_1 - t_1 l}{t_1 - t} \dots\dots\dots\dots\dots\dots [3]$$

Thus the experimental determination of the time for each of two double strokes only was necessary for the derivation of the value of a, and hence, if three values of t were determined experimentally, these must result in three derivations of a that must substantially be alike, if the experiments were conducted with care.

Mr. Barth then showed that Equation [3] applied to the data in Table 1 of Mr. Meier's paper would give for cast-iron pulleys the following three values of a: 7.72 in., 4.08 in., and 13.48 in., which were far from substantially alike. For the aluminum pulleys were similarly obtained for a the three unequal values 4.17 in., 5.37 in. and 7.18 in.

However, while data obtained by experiments with two different strokes only were theoretically enough for the determination of the value of a, the foregoing investigation showed the necessity of taking at least three strokes, as Mr. Meier had done, and then in addition to this, to work with such care and circumspection that the three values of a independently obtained would be near enough alike for all practical purposes. His method was to plot, as in Fig. 1, the simultaneous values of l and t, with the latter obtained by means of a stop watch on which was read the time it took for the completion of an exact number of double strokes of a carefully measured stroke.

It would readily be seen in Fig. 1 how a was graphically determined by the straight line AB drawn to pass through the three points C, D and E, when these represented a set of consistent results obtained.

After similarly plotting all of Mr. Meier's results, and taking it for granted that a only and not C in equation [1]

was affected by the substitution of aluminum pulleys for cast-iron pulleys, he had by inspection attempted to eliminate the grossest errors of Mr. Meier's observations and to write equation [1] as

$$t = 0.0354 \quad (l + 1.125) \quad \text{for cast-iron pulleys}$$
$$t = 0.0354 \quad (l + 0.45) \quad \text{for aluminum pulleys.}$$

If he had succeeded in getting closely to the truth in arriving at these equations, the value of 1.125 ft. = $13\frac{1}{2}$ in. for the cast-iron pulleys, as against only 0.45 ft. = 5.4 in. for the aluminum pulleys, was certainly the plainest way of showing up the superiority of the latter.

Mr. Meier gave the forward speed of the planer as 40 ft. and the return speed as 90 ft., which would make the value of C in these equations = (90 + 40) / (40 × 90) = 0.03611; but the plots he had made seemed to indicate that this value was too high, so the value 0.0354 was chosen. However, assuming $V/v = 90/40$, or $V = 2.25v$, and writing

$$C = 0.0354 = \frac{V + v}{vV} = \frac{2.25v + v}{2.25v^2}$$

gave $v = 40.8$ ft. and $V = 91.8$ ft., which were not very far from the figures given by Mr. Meier.

In Par. 11 Mr. Meier made the unqualified statement that the aluminum pulleys also "effect quite a saving in power," and then stated, by pointing to the figures in Table 2, that for a 76 x 62 x 32-ft. planer this amounted to 25 per cent, while he evidently had in mind only the maximum power expended during the period of reversal.

As the power during reversal was principally expended in overcoming the inertia of the pulleys, the total amount of this power must be more nearly proportional to the weights of the respective pulleys, while the 25 per cent of greater peak load could be explained by the well-known fact that a belt would pull the most when it slipped the most, as it no doubt would when forced to stop and start the heavier cast-iron pulleys.

However, the power expended in reversing was of no consideration as compared with the wear and tear on the belts themselves and other parts of the reversing mechanism.

Charles Fair said that Mr. Meier had brought out a number of important points which should receive serious consideration. For a long time he had felt, as Mr. Meier did, that neither the planer manufacturer nor the planer user had given the question of handling the work or the cutting anything like the consideration it deserved. It was generally admitted, for instance, that higher cutting speeds were possible if the tool entered the work slowly and then speeded up, yet information was very meager as to how seriously this would affect the work.

On heavy roughing cuts the spring due to the increased pressure on the tool while speeding up in the work would probably be noticeable with tools not properly shaped. If only roughing cuts were required, a fine degree of accuracy would not be essential. If roughing and finishing cuts were made, he doubted if the inaccuracies, due to speeding up in the light cut, would be noticeable. From such tests as he had made this difference was not great. He had again brought up this question of speeding up in the work because, should it be required, it was very easy to accomplish with the reversing motor drives, as is also slowing down before leaving the work to prevent breaking out the metal.

Production on planers could certainly be speeded up by a more liberal use of jigs and fixtures and in many cases double sets of jigs could be used to advantage where considerable duplicate work was being machined. This would be particularly true in cases requiring time to properly set the work.

Mr. Barth was a little hasty when he criticized Mr. Meier's paper, largely, he would judge, on the grounds of its being practical only and not consistent, presumably, with his theory. In this particular case, however, the correct theory did agree with the facts. Mr. Barth's whole theory was built on an incorrect assumption, namely "that the time consumed in stopping and reversing the planer table at the end of each stroke must be independent of the length of the stroke." This assumption on Mr. Barth's part was exactly where he erred and was presumably the reason why his theory and Mr. Meier's tests did not agree. The time of stopping and reversals varied materially with the length of stroke, as could be easily shown by tests, particularly in the case of the belt-driven planer. Further, this variation was noticeable in some cases up to a 10-ft. stroke; however, a 4- to 5-ft. stroke usually covered the noticeable variation. It would not only be necessary for Mr. Barth to substitute a variable in his equation for the different

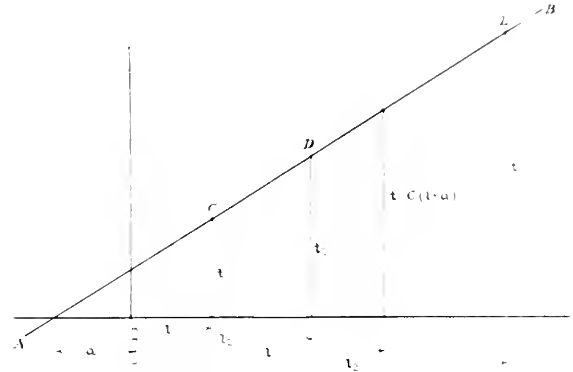


FIG. 1 METHOD OF DETERMINING VALUE OF a

lengths of stroke, but this variable in turn would necessarily have a different value when applied to drives of the single-belt-shifting type, the rocking-idler type, the double-belt-shifting, magnetic clutch, pneumatic clutch and direct-connected reversing motor drive. These in turn would all be affected by the different weights of the revolving parts, and in the case of the belt drives by the tension of the belts and by the time that it took for one belt to get from the loose to the tight pulley and the second belt from the tight to the loose pulley. There were, of course, many other elements that entered into the problem but the above were the main ones that would affect the constant a.

Mr. Barth's formula would be correct if V were a constant rate of speed instead of a variable rate of speed. An average velocity of V could not be used to determine a. Therefore, the formula would be good only in cases where the machine had reached full speed and then only under the conditions for which the actual value of a was obtained. If a were obtained under no-load conditions it would not apply when cutting if the shifting for the reverse occurred before the tool was out of the work. The changing value of V was even more noticeable when the machine was operating under load. Fig. 1 in Mr. Barth's discussion illustrated a very simple method of obtaining a provided it were an equation of the first degree. In reality, however, it was an equation of the second degree, which meant that a would have a continually changing value depending on the changing value of V and its effect on the stopping of the platen.

If Mr. Barth's Planer Time Slide Rule was based on the formula cited, it would have to be remodeled before any claim for accuracy could be made.

GENERAL SESSION, TUESDAY MORNING

The Business Meeting on Tuesday morning was followed by a General Session, at which four papers were presented and discussed, as follows: Tests of Uniflow Steam Traction Engines, F. W. Marquis; Relation of Efficiency to Capacity in the Boiler Room, Victor E. Phillips; Radiation Error in Measuring Temperature of Gases, Henry Kreisinger and J. F. Barkley; and Development of Scientific Methods of Management in a Manufacturing Plant, Sanford E. Thompson, William O. Lichtner, Keppele Hall and Henry J. Guild.

A paper on Disk Wheel Stress Determination, by S. H. Weaver, was also presented at this session by title.

PROFESSOR MARQUIS PRESENTS HIS PAPER

The first paper presented was that of Professor Marquis, giving the results of two series of tests of Baker uniflow steam traction engines. The steam consumptions of these engines were compared with those representative of the or-

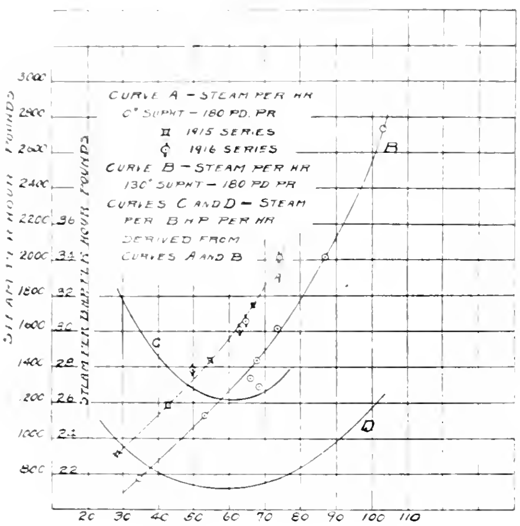

Fig. 1 Replot of Author's Curves

dinary counterflow type of engines, and the conclusion was reached that the uniflow engine tested, operating non-condensing with saturated steam, had a lower steam consumption than the compound counterflow engine under like conditions. Also, when operating non-condensing with superheated steam, it would have approximately the same steam consumption as a compound counterflow engine operating condensing on saturated steam.

Written discussions of this paper were contributed by J. E. Emswiler, George H. Barrus, L. V. Ludy and E. T. Adams. The paper was discussed orally by R. J. S. Pigott, C. H. Benjamin and A. G. Christie, and Professor Marquis replied to the discussion.

J. E. Emswiler, in a written discussion, considered that it would seem preferable, in most cases, to refer the steam consumption in the curves to b.hp. instead of i.hp., and especially so in these tests, where considerable discrepancy appeared if the i.hp. was plotted on b.hp. Such discrepancy must necessarily be blamed upon the i.hp. rather than upon the b.hp., since the latter was much more simply and easily determined in the tests.

The table for the 1916 series furnished some valuable information concerning the influence of superheat on steam consumption for a uniflow engine.

Test 7-180-4 was made with a load of 73.3 b.hp. and a superheat of 136 deg. Correcting the steam consumption to a load of 74 b.hp. gave a steam consumption per b.hp-hr. of 21.8. Test 16-180-4 at a load of 74 b.hp. gave a steam consumption per b.hp-hr. of 27.2 at 0 deg. superheat. This was a gain of 5.4 lb. for 136 deg. superheat, or 24.7 per cent, which was 18.2 per cent per 100 deg.

Again, test 10-180-3², at a load of 67.6 b.hp. and a superheat of 131 deg., showed a steam consumption of 21.3 lb. per b.hp-hr. Correcting in a similar manner to a load of 64.7 b.hp., the steam consumption became 21.6. Test 15-180-3, at a load of 64.7 b.hp. and 0 deg. superheat, gave a steam consumption of 25.6 lb. per b.hp-hr. This was a gain of 4.0 lb. for 131 deg. or 18,5 per cent, which was 14.2 per cent per 100 deg.

The average of the two examples was 16.2 per cent per 100 deg. of superheat, based on the steam consumption which accompanied the superheat.

Applying this correction factor to reduce the tests made with superheated steam to a common basis of superheat, say 130 deg., and plotting corrected steam per hour against b.hp., the curve *B* of Fig. 1 was obtained..

The curve *A* was obtained by plotting the steam per hour of the tests of both the 1915 and 1916 series, at 180 lb. pressure and 0 deg. superheat, against b.hp.

It was very instructive to plot the total steam per hour against the output, as was done in Fig. 1, for two reasons. In the first place, where a number of points were available, as was the case here, such curves served to distinguish those tests which were probably in error from some cause or other, from those which were accurate. It was evident from the curves of Fig. 1 that some discrepancy existed in connection with tests 6-180-3, 11-180-3², and 14-180-2.

In the second place, these curves were instructive as exhibiting a characteristic of the uniflow engine different from that of either a counterflow engine or a steam turbine. The steam-per-hour curve of the uniflow engine had a marked and continuous bend; while for the counterflow engine, or steam turbine, the curve was usually straight, at least for the greater part of its length.

The indicator diagrams in the paper showed a rise in the back pressure from the time the central exhaust ports were closed by the piston until the auxiliary exhaust port was closed. This was probably due to wiredrawing in the auxiliary exhaust port and represented some loss. Undoubtedly, from the standpoint of economy alone, the engine would be better without the auxiliary port, that is, operating on the strictly uniflow principle. However, it was presumable that the purpose of the additional port was to secure greater capacity, which it did by giving thicker diagrams than would be obtained without it.

George H. Barrus wrote that the tests reported were not tests of a " uniflow " engine, but they were tests of what might well be called a counterflow-uniflow engine, with the counterflow features in the lead.

There was nothing in the paper, so far as he could see, showing that the uniflow characteristics possessed by the Baker engine had anything to do with the superior economy reported. In fact, he could not see that these characteristics were sufficiently pronounced to produce any marked influence on the

results. The indicator diagrams were not materially different from those that would be given by any counterflow engine having the same valve gear and working under the same pressure and speed.

To justify the conclusion that the superior results given were due to any uniflow characteristic, a comparison should be made between the engine in question and an ordinary counterflow engine having the Baker valve gear, but the paper made no such comparison. All that the paper showed was the difference in economy between an engine having excellent steam distribution, such as that obtained by the Baker valve gear, and ordinary throttling slide-valve engines having defective steam distribution, which at best gave very poor economy.

If the title of the paper were changed to read Tests of Counterflow-Uniflow Steam Traction Engines, and the term "counterflow-uniflow" were substituted for "uniflow" throughout, the conclusions would be less liable to be misconstrued than they were in its present form.

L. V. Ludy reported the results of a series of tests on a Huber steam tractor a few years ago which gave some very interesting information in comparison with the tests reported in the paper.

The engine was fitted with a common D slide valve, which was unbalanced. The boiler was of the marine type, having a large flue extending throughout the entire length of the boiler, the back end of which served as a firebox. No superheater was provided. The method employed in carrying out the tests was exactly similar to that used by Mr. Marquis.

Table 1 gives the principal dimensions of the tractor, and Tables 2 and 3 the general results obtained.

In the results reported by Mr. Marquis, the maximum i.hp. in per cent of the normal rated hp. was unusually high. The results obtained from the 1915 engine were over 160 per cent and those from the 1916 engine about 600 per cent. Similar results reported by the writer gave this ratio of the greatest i.hp. to the normal rated hp. to be over 230 per cent, but in this case the engine was not operated at maximum load.

TABLE 1 PRINCIPAL DIMENSIONS OF HUBER TRACTOR

BOILER		ENGINE	
Number of tubes	18	Nominal horsepower	18

Length of test, min.	Boiler pres., lb. per sq. in. gage	Coal fired per sq. ft. of grate surface per hr., lb.	Equiv. evap. per sq. ft. water-heating surface per hr., lb.	Equiv. evap. per lb. air-dry coal, lb.
60	110.8	14.3	5.58	10.25
120	111.7	24.5	7.75	8.30
60	112.4	27.1	8.72	8.44

E. T. Adams wrote that a moderate-power steam traction engine weighed at least 300 lb. per hp. It was therefore far too heavy for ordinary farm work and was really a portable power plant with its earning power practically limited to the threshing season. It was another example of a type of machine all too common on the farm which disintegrated from idleness rather than from use. The short earning and long rusting season was the vital disease affecting the traction engine. The remedy was a longer earning season, which might be secured by any change which would reduce the weight of these machines to a figure approaching 100 lb. per hp., thus making them available for plowing, disking, harrowing and seeding, as well as for threshing and other belt work. Increased economy could make this possible, but a minor increase would not be sufficient—it would have to be great enough to reduce greatly the size of the boiler, or even allow the use of a new type.

He thought that the A. D. Baker Company certainly deserved great credit for their endeavors to improve the economy of the farm tractor and had made a step in the right direction, because, although their coal consumption per b.hp-hr. in these tests was greater than that shown on single-cylinder tractors at the Canadian Industrial Exhibition tests in Winnipeg in July 1913, the steam consumption per i.hp-hr. was about 8 per cent. better when operating under the same conditions.

It seemed too bad, however, that they had not gone a step further. Their engine was undoubtedly a uniflow engine, in that it took steam at the end of the cylinder and exhausted at the center, but it did not use the thermal cycle which had made the engine commonly known as the uniflow engine so popular in Europe and, more recently, in this country.

The advantage of this European thermal cycle was illustrated by comparison of these tests of the Baker engine with tests made by Government licensed engineers on a portable engine of approximately the same horsepower and under about the same conditions, built by the Maschinenfabrik Badenia, of Weinheim. The Badenia engine had a normal brake horsepower of 120. The steam pressure was slightly lower and the superheat slightly higher than in the Baker engine. The Badenia engine showed an economy of 13.8 lb. of steam per i.hp-hr. and 1.83 lb. of coal per b.hp-hr. The Baker engine, therefore, required 38 per cent. more steam per i.hp-hr., and about 80 per cent. more coal per b.hp-hr.

As Mr. Marquis did not give the heat value of the coal used on the trials, it was impossible to get a close basis of comparison on the coal consumption. The coal used at Winnipeg had a heat value of 14,470 B.t.u. and at Badenia the heat value of the coal was 13,800 B.t.u. It would be noted that both the Winnipeg and Badenia trials were made by experts not in any way interested in the engines being tried.

R. J. S. Pigott said that in considering the curves of water rate and boiler efficiency he had found it extremely valuable to make use of the input and output, or Willans line, rather than the water-rate or efficiency curves.

In the first place, the Willans line for all throttle-governed engines, and for all turbines, up to the point where the relay valve opens, was substantially straight. For the automatic engine, the line was represented by an equation of the second

economy and was raised upward more or less. The valuable feature was that as these Willans lines were either straight or only slightly curved, and the zero steam consumption always fell within reasonably well defined limits—say 15 to 20 per cent of full load steam consumption, the direction of the curve could be very much more definitely settled, especially if the tests varied considerably from average. The water rate curve could then be plotted from the Willans line.

One feature of Fig. 12 of the paper which seemed peculiar was the crossing of the lower boiler pressure curves by the 175-lb. curve at low loads. This was very unusual, as in all cases he had seen, the raising of the boiler pressure improved the water rate and lowered the Willans line at all loads. The crossing of the water rate curves indicated that the Willans line also crossed those at the lower pressures, giving a high no-load steam consumption, which was extraordinary. He would in general suspect an error, especially as the tests seemed short for accurate results by the feedwater method. Quite large errors were introduced by the capacity of the system and the impossibility of getting accurate indications of water content of the boilers by gage glasses; the shorter the test, the larger the effect of the error.

A further suggestion to the author was that the results be computed in thermal efficiency, Rankine-cycle efficiency ratio, and B.t.u. per hr., all referred to brake horsepower; the variations with i.hp. were of little value for a comparison with other types of prime mover.

The thermal efficiency was a basic measure of the real economy; so was B.t.u. per b.hp-hr. Water rates were not basic and varied with every set of steam conditions. The Rankine-cycle efficiency ratio was a valuable means of comparing the design of one engine with another, since it showed how well the engine made use of its steam range, although the thermal efficiencies might be very different. For instance, the efficiency ratio of a non-condensing compound engine might be as high as 75 or 80 per cent, and its thermal efficiency only 7 to 10 per cent; that of a condensing compound, 55 to 60 per cent, and the thermal efficiency 16 or 17 per cent; showing, as we now well knew, the extremely low efficiency ratios of low-pressure cylinders under condensing conditions.

These two efficiencies were the only ones of value in comparing steam results with internal-combustion-engine results. Messrs. Stott, Gorsuch and the speaker had advocated, in a Prime Mover Committee report for the A. I. E. E., 1915, that the use of water rates be abandoned as not basic, and that the above efficiencies be substituted.

A. G. Christie wrote that the paper gave some excellent data of the effect of superheat in a uniflow non-condensing engine. Considerable emphasis had been laid on the comparison of the uniflow and counterflow engines, and the curves in Fig. 14 showed comparative performance curves for several types of engines. It did not seem that any of these curves showed compound-condensing units with superheat.

In large power plants there was a tendency to increase both steam pressures and superheat. The tests in this paper showed the highly beneficial effect of adding superheat in a non-condensing unit. Engineers should therefore be interested in the performance of a small unit with high pressure, high superheat, reheating between cylinders, feedwater heating and condensing.

When the new laboratories of Johns Hopkins University were built, a 75-kw. Buckeyemobile was purchased from the Buckeye Engine Co., and direct-connected to a 50-kw. generator. This unit had been used to carry the summer light and power load of the University, and for test purposes by the students during the winter months. A portion of the test results was given in Table 1; the results were obtained by members of the senior mechanical-engineering class in a series of tests made last winter. The unit was not prepared especially for test and was operated as in general service. It was felt that the results represented very closely average operating conditions, though other previous tests had indicated lower coal consumptions at the various loads.

TABLE 1 PART OF RESULTS OF TESTS ON 75-KW. BUCKEYEMOBILE

Dry coal per i.hp-hr.	2.32	1.57	1.40
Dry coal per kw-hr., lb.	4.06	2.55	2.27
B.t.u. in coal consumed per kw-hr..	57,453	34,540	31,280
Lb. of steam condensed per i.hp-hr..	10.80	10.5	9.63
Lb. of steam condensed per b.hp-hr.	12.65	11.32	11.0
Lb. of steam condensed per kw-hr	18.94	17.0	15.62
Efficiency ratio of engine based on indicated horsepower, referred to adiabatic expansion, per cent.....	64.3	67.0	72.7
Efficiency of boiler alone, per cent	36.8	55.1	55.4
Efficiency of boiler, superheater, reheater and feedwater heater, per cent	43.2	64.6	66.3
Efficiency of complete plant from kilowatts at switchboard to heat in coal as fired, per cent...	5.92	9.88	10.85

The unit had given very satisfactory service since it had been installed, and the operating and maintenance charges had been quite low. American engineers could well afford to give more attention to this type of unit with the rapidly increasing costs of fuel and labor.

PROFESSOR MARQUIS REPLIES

Professor Marquis, in replying, agreed with Professor Emsweiler that it was often preferable to refer steam-consumption curves to b.hp. instead of i.hp. In the present case the difference in the form of the curves would be very slight, and it was decided to use i.hp. in view of the fact that it proved more difficult to find results of tests of engines, with which it was desired to make comparisons, expressed with reference to b.hp.

In answer to Mr. Adams' question, the heat value of the coal used was approximately 13,700 B.t.u per pound, as fired.

In reply to Mr. Pigott's suggestion that the fact that the water rates were not in all cases lower, at all loads, with higher boiler pressure than with lower boiler pressure, indicated an error, and that the results might be adjusted with the aid of the Willans lines so as to eliminate this feature, he would like to call attention to the fact that if a Willans line was plotted for each boiler pressure of the saturated-steam runs, a very clearly defined tendency throughout for the higher-pressure lines to cross the lower-pressure ones at light loads would be evident. It was realized that the work doubtless contained some experimental errors, but it did not seem reasonable to infer that errors would occur in such a way as to consistently indicate the same thing. It did not therefore seem justifiable to adjust the results as suggested.

Moreover, it was evident that the cylinder condensation would be greater with high boiler pressures, due to the increased temperature ranges, than with lower ones. It did not seem unreasonable to infer that as the load became lighter and the cut-off earlier, a point would finally be reached where the loss due to increased cylinder condensation would overbalance the gain due to increased available energy, and the Willans lines cross, as actually indicated by the data presented.

He agreed entirely with Mr. Pigott as to the value of the use of the thermal efficiency, B.t.u per hour (or per minute), and the Rankine-cycle efficiency ratio, for comparison with other types of prime movers. The Rankine-cycle efficiency ratios referred to i.hp. would be found in column 12 of Table 2. The others were not presented in the paper.

PROFESSOR BENJAMIN TAKES THE CHAIR AND MR. PHILLIPS' PAPER IS PRESENTED

At this point, President Hollis appointed Vice-President Charles H. Benjamin to the chair, and Victor B. Phillips' paper on Relation of Efficiency to Capacity in the Boiler Room was presented by the Secretary in the absence of the author.

In this paper the author showed, by typical cost figures, that 90 per cent of the cost of producing steam was for fuel and fixed charges (including labor). He stated that these two charges were of almost equal importance, and that their reduction depended respectively on the attainment of efficiency and capacity. He then set about to establish the procedure for determining the relation of maximum efficiency at various loads to those variables of operation which the fireman might observe and over which he must exercise control. Test data on a B. & W. boiler, equipped with a Taylor stoker for a very wide range of operating conditions, were used to illustrate the procedure and to show the validity of the selection of variables.

The data applying to the furnace and boiler were shown respectively in charts having efficiency and capacity as coördinates, and the interrelation of the operating variables was indicated, as on steam charts, by lines of constant values. These two charts were then combined into a single chart having as coördinates overall efficiency and capacity of the steam-generating plant, and which graphically represented the two objects to be sought—efficiency and capacity—in terms of the variables of operation through the manipulation of which they might be obtained. The striking test results shown in the furnace-operation chart were discussed in an appendix, which also gave details of the procedure employed.

This paper was discussed orally by William Kent, L. C. Bowes, W. F. M. Goss and J. M. Spitzglass, and written discussions were contributed by R. C. Carpenter, Maxwell Alpern, George H. Barrus, Bryant Bannister, and N. G. Reinicker.

William Kent said that about twenty-five years ago he stated before the Society that the relation of efficiency to capacity of a boiler was not expressed by any curve or formula, but by a field the upper limit of which represented the results that could be obtained under the best possible conditions. The width of this field was very great, and was a measure of our ignorance concerning how to get the best conditions.

His studies for forty years had been directed toward helping to narrow the limits of this field, which had now been done to the extent that the action of a boiler could be predicted to within 5 per cent or less when the duty was known.

In regard to the thickness of the fire, some thirty years ago he made a 24-hr. test with pit coal and with every facility for making a good observation. The test was divided into 8-hr. periods and the first period was run with thin fires, the second with medium fires, and the third with thick fires. The best results were obtained with thin fires and with thick fires, and the worst with medium fires. From these data he did not think anyone could draw any conclusion.

In 1895 he made a series of 75 tests on a Babcock & Wilcox boiler, with a great many variable conditions. Some of these tests run with thick fires and strong draft gave results within 1½ per cent of those obtained with thin fires and moderate draft, again leading to no conclusion as to the merits of thin fires and thick fires.

In regard to carbon monoxide, he had a series of apparatus arranged so that gas samples could be taken from half way through the boiler tubes every minute. The first minute gave no oxygen and 7 per cent CO_2; the second minute 4 per cent CO_2 and a trace of oxygen, and at the end of five minutes 7 per cent free oxygen and no carbon monoxide. This showed the tremendous variation in conditions that could exist inside of five minutes.

This test led to no conclusion as to the CO_2 except that it was extremely variable. Results of 75 tests were plotted against every variable, and such conclusions drawn as could be.

What conclusions he had obtained in nearly forty years of making boiler tests were to be found in his Steam Boiler Economy. A little differential calculus had been used in dealing with the problem; but it seemed to him that all investigators had entirely ignored that study. He hoped Mr. Phillips would check his results against the things given in that publication and see if they did not reach more definite conclusions than in the paper.

L. C. Bowes thought the paper pointed out one very essential thing: that the maximum efficiency was gained at about 25 per cent overload. There seemed to be a great tendency at present for stoker manufacturers to recommend stokers to fire above the rated capacity of the boiler, for which tendency central-station practice had probably been responsible.

With a stoker and boiler giving a high overload capacity, with a 12-hr. peak, the loss in the boiler due to high overload capacity in order to operate the stoker at an efficient point would exceed the loss due to maintenance charges on additional boiler capacity, with stokers somewhere near consistent with the rating of the boiler. This point was very essential where there was a standing load on a 10-, 12- or 24-hr. peak.

In central-station practice, where there was only a three- or four- or sometimes a single-hour peak, high boiler capacity of course was required, but he would like to see some curves showing in some way the relation between the fixed charges and fuel cost dependent on varying relations between the stoker capacity and the boiler capacity.

W. F. M. Goss said that in our efforts to increase efficiency we were likely to lose sight of a matter of considerable present-day importance to which mechanical engineers should give due attention. He referred to the increase in the pollution of the atmosphere which resulted when boilers were driven to higher capacities.

The record of locomotive-boiler performance had long since disclosed the fact that stack losses in the form of solid particles of fuel constituted a most important factor in their effect on boiler efficiency. We knew that as we increased the capacity of a locomotive boiler we also increased the percentage of solid fuel passing up the stack. For locomotives in which a third and sometimes a half hp. was secured per square foot of heating surface, the relation of solids (fuel and ash) passing up the stack to rate of combustion was known for a considerable number of different fuels. There was very little similar information applying to boilers in power plants, notwithstanding the fact that we were constantly increasing the rates of combustion in such plants, and by so doing bringing stationary practice to a point where it overlapped a portion of the field covered by locomotive service.

Mechanical engineers were naturally interested in that

aspect of the question which affected boiler efficiency. His present purpose was to urge the importance of their being interested in that aspect of the question which affected the purity of the atmosphere.

J. M. Spitzglass said that he would not hesitate to say that the relation between operating efficiency and capacity was *the* most important factor in the boiler room, also in the engine room and, in fact, in every unit of a plant.

The author had two objects to accomplish in his paper: to demonstrate that the boiler operation should be studied systematically in relation to the two fundamental variables, *efficiency* and *capacity*, and to actually study this relation. While he succeeded in accomplishing the first object, he utterly failed in the second.

He regarded the author's treatment of the furnace factors as very interesting, indeed. The combination of an air meter and draft gage, assisted by the analysis of flue gases and readings of temperatures, would answer very well if there were always some reliable person whose duty it would be to take these various readings.

When it came to the boiler, however, after demonstrating that the relation between efficiency and capacity was the most important factor in operation, the author did not suggest the direct method of indicating or determining the capacity of the boiler at all times, which was by a steam meter. He merely contented himself with saying that the factors governing furnace operation should also govern boiler operation.

It was not to be denied that some idea of the capacity could be obtained from the conditions of the furnace and measurement of air supply when six extra men, trained for the purpose as was the case in the paper, were present to observe and manipulate the readings of the various devices operated during the test. But, how many firemen would be found who were able to observe air velocities, draft-gage readings, gas analyses and flue-gas temperatures; and if they were, how many could interpret them? Many places would be found where most of these instruments were present but were seldom followed by the firemen, but Mr. Spitzglass had yet to see the place where a boiler-steam meter was installed that it was not watched by the firemen the same as the pressure gage or the time clock.

Some might object that the steam-flow meter was not 100 per cent accurate. It was not; neither were any of the attachments to the furnace, as far as he knew. The author had demonstrated that under a given set of conditions, differential pressure readings would repeat themselves for the same quantities they represented. It stood to reason that the flow meter, which was merely the index of the differential pressure corresponding to the flow, would repeat itself for the same flow, and by weighing the feedwater for only a short period, the absolute calibration might be readily obtained for each boiler or line.

But this calibration, or even the whole accuracy, was not the question of the boiler steam meter at all. The main object was having something definite and comparatively accurate striking the fireman's eye at all times—something that he could easily understand without any interpretation or calculation.

The fireman had a problem which we seldom realized. With no steam meter on the line, he did not know what the boiler was actually producing, he merely guessed at it. The demand for steam was out of his control and knowledge. Suppose he learned that by following a certain operation he kept up the pressure at a given time, how was he to know what the actual demand was at that time, or, as the author put it, what the capacity of the boiler was at that time?

We could not expect a fireman to operate efficiently from a set of charts drawn up after a boiler test. But, when he saw that by performing a certain operation he caused the steam meter hand to move to the high-capacity side, he visualized the result and would surely repeat the same operation, knowing it effected better and easier work in general.

R. C. Carpenter thought that the paper represented the first series of investigations so conducted as to determine the results produced by greatly varying the coal consumption.

It was a matter of regret that in the tests the limit of air supply rather than the heating surface proved insufficient for complete combustion at the highest limits of coal consumption. Lines 13 and 15 of Table 2 gave information as to the drop in efficiency following the increase in the combustion of coal as indicated on line 3. The determination of the weight of air employed for the combustion of the fuel afforded an opportunity for noting the effect due to the regulation of the air supply, which important matter had seldom been given consideration in boiler tests. The particular air meter employed was of interest, as were also the scientific results given as proper conclusions drawn from the investigation.

The records of the investigation would be of great value in determining the limit of capacity of steam boilers, which was now under consideration in every recent construction. Obviously as the limit of capacity for a given efficiency was increased, the overhead and operating costs were reduced.

M. Alpern, in pointing out some of the operating faults of the tests, particularly as they affected the performance of the Taylor stoker used, spoke as follows:

"Theoretically, the Taylor stoker consists of an inclined retort, throughout which the air pressure is supplied under constant pressure and through constant areas of air discharge; an auxiliary grate surface at the rear of the inclined retort for the purpose of burning out the devolatilized fuel, and a substantially imperforate dump plate on which the residue can remain for a relatively long period, for the purpose of further reducing the carbon in the refuse and discharging the refuse into an ashpit. In operation it is intended that a maximum fuel-burning effect shall take place in the space occupied by the mouth of the retort and that the feed of the fuel in the retort shall be so regulated by the adjustable feeding mechanism that the fuel will rise from the mouth of the retort uniformly throughout. Such of the fuel as remains unburned together with the refuse feeds over the auxiliary grate at the rear, which grate has a hand-regulated air supply. This air supply can be regulated from zero to a maximum opening.

"Technical operators are instructed in the operation of the Taylor stoker by observation of the fire only. When properly adjusted and properly operated, the fire will go through a regular cycle. The mixture of fuel and ash will be deposited on the dump plate until the plate is covered to a depth of possibly 12 to 15 in. While the stoker continues to operate, the material is deposited on the dump plate only as the material already there wastes away by the process of combustion and provides room for it. Accordingly, at the end of a period of 3 or 4 hours, the material on the dump plate takes on a dead and, to some extent, blackened appearance. This indicates that the time has arrived to dump. At what are normally known as low rates of combustion, that is, rates of combustion below 500 lb. per retort per hour, no air is used on the auxiliary grate, that is, the damper is closed. A

small amount of air may escape through leakage. Except just prior to the dumping period, for an interval of perhaps 15 minutes, the damper is open (sometimes wide open, sometimes only part way open). It is only at rates higher than 500 lb. per retort that there is any opening of the damper through the period of operation between dumps. If the stoker does not go through the regular cycle and produce a time, and it would also appear that the fuel bed was not properly adjusted.

"The accompanying curves will clearly indicate the trouble. In Fig. 1 are plotted first the efficiencies obtained by Mr. Phillips with light, medium and heavy fuel beds. In the same figure are shown the efficiencies obtained on the Taylor stoker of exactly similar design with the same ratio of heating

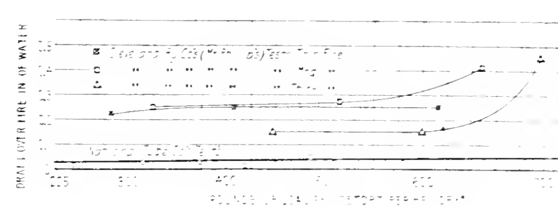

FIG. 6 COMPARISON OF DRAFT OVER FIRE

burned-out ash at the end of a 3- or 4-hr. period, no better indication need be had that one of two things is wrong. Either insufficient air is being supplied to the fuel emerging from the retort, or the feed of the lower ram is not adjusted properly. These adjustments are very simple to make. It is apparent in the tests reported by Mr. Phillips that the air supplied to the fuel over the retort was insufficient, the damper to the extension grate was wide open all the surface to grate surface, on tests run at the New York Edison Company. The coal used in the latter tests was somewhat better than the coal used during the Cleveland Railway tests.

"In Fig. 2 are indicated the air-pressure curves. The air pressure in both the New York Edison tests and the Cleveland Railway tests represent the difference in pressure between the windbox of the stoker and the furnace over the

of fuel. It will be noted that the New York Edison tests show very much higher pressure at corresponding rates of fuel burning.

"Fig. 3 shows the draft over the fire, in the case of the New York Edison tests and the Cleveland Railway tests. The draft over the fire in the latter tests was materially higher, as, of course, was the draft throughout the boiler, causing a larger loss from infiltration of air.

"Fig. 4 illustrates tests run on a Taylor stoker of similar design with a similar ratio of heating surface to grate surface at the National Tube Company, Kewanee. In this case, a much lower grade of fuel was burned than that reported in Mr. Phillips's tests.

"Fig. 5 shows the relative air pressures between the National Tube Company tests and the Cleveland Railway tests. In the case of these tests, the air-pressure curves are much closer together, owing to the fact that the actual combustible burned with Illinois coal was much less per pound of dry coal than was true of the coal burned at the Cleveland Railway tests.

"Fig. 6 illustrates the draft over the fire.

"Fig. 2 also shows the air pressures used by Mr. Phillips at corresponding rates of combustion per pound dry coal. It will be noted that with the heaviest fuel bed the lowest air pressures were employed, and with the thinnest fuel bed the highest air pressures were employed, which is just contrary to what is necessary for good operation. The heavy fuel-bed condition was an unnatural one for the Taylor stoker, and existed only because the fire was starved for lack of air."

George H. Barrus wrote that the paper stated that the "fuel bed was kept uniform and constant in thickness by very close and frequent observation on the part of three different men, all experienced firemen." From this it was evident that "the flying start and stop" was the method pursued in beginning and ending the tests. Everyone who had had experience with the operation of Taylor stokers realized that it was almost impossible for an observer, whether an experienced fireman or expert, to judge of the exact condition of the fuel bed in the regular operation of such a stoker. It was therefore well-nigh impossible to make a flying start and stop with a stoker of this kind and be assured that the condition was anywhere near the same at the beginning as at the end of a test.

Realizing this, the Power Test Committee of the Society had prescribed certain rules regarding the duration of stoker-fired tests and the method to be employed in starting and stopping them.

In regard to duration, he quoted from Par. 45 of the Power Test Report, as follows:

> In the case of a boiler using a mechanical stoker, the duration, where practicable, should be at least 24 hours. If the stoker is of a type that permits the quantity and condition of the fuel bed at beginning and end of the test to be accurately estimated, the duration may be reduced to 10 hours, or such time as may be required, to burn the above noted total of 250 lb. per sq. ft.
>
> In commercial tests where the service requires continuous operation night and day, with frequent shifts of firemen, the duration of the test, whether the boilers are hand-fired or stoker-fired, should be at least 24 hours. Likewise in commercial tests, either of a single boiler or of a plant of several boilers, which operate regularly a certain number of hours and during the balance of the day the fires are banked, the duration should not be less than 24 hours.

There was nothing in Par. 45 that permitted a test of the Taylor type of stoker to be less than 24 hours in duration, in a plant like the one in question operating for 24 hours per day.

Mr. Barrus also called attention to Par. 48 of the Power Test Code, which related to the starting and stopping of a stoker test, in order to show that there was nothing in the requirements that countenanced the flying start and stop, which appeared to have been followed in the tests reported in the paper.

Bryant Bannister[1] wrote that the author had invited discussion which should be quite beneficial to boiler-plant designers. It went without argument that the designer should attempt to provide the maximum of capacity with a given investment, without corresponding contingent losses. With the data available pertaining to heat transmission through setting walls, boiler tubes, etc., we could safely design a boiler plant for what might be termed "intensive steam production."

Since the two greatest sources of heat loss in steam production originated in the boiler furnace and through the boiler proper, we could expect the greatest interference with the design for maximum steam production either in the stoker or the boiler proper. It was possible to meet the first interference by the use of stoker equipment which improved the furnace efficiency as the rate of fuel consumption was increased. One make of stoker had this important characteristic up to a burning rate of about 1000 lb. of coal per retort per hour, and possibly further. Referring to Fig. 2 in the author's paper, it would be noted that a curve connecting the points of maximum furnace efficiency had an upward trend, rising from 68 per cent at a furnace output of 555 boiler hp. to 76 per cent at 1055 boiler hp. output. It then became the duty of the boiler unit to absorb the heat evolved without unduly high exit-gas temperatures.

The second interference pertaining to heat transfer into the boiler had been very admirably treated by Messrs. Kreisinger, Ray and Barkley in Bulletin 18, and Technical Paper 114 of the Bureau of Mines. These papers were both splendid arguments for greater capacity from a given boiler heating surface.

Presuming commercially clean tube surfaces, both inside and out, it followed that we must go further than was usually considered good practice toward providing for a long gas passage in contact with tube surface, also toward increasing the gas velocity. Just where we should stop with the boiler surface proper and introduce economizer surface must, of course, be governed by local conditions, costs, etc., but the writer believed that such economizer surface could be provided adjacent to the boiler, preferably above, with tubes of suitable size and so arranged that high gas velocity was obtained, in many cases with a single pass for gas flow.

Because large boiler units lent themselves so well to the above scheme they should be given consideration as an essential feature in the design.

If the principle of "intensive steam production" was adhered to in both design and operation, the result would be minimum investment per unit of steam produced, while the cost of operation, including fuel, labor and material for repairs and maintenance, etc., would not be increased much over similar costs for normal steam production.

The tendency toward the proposed design was apparent in central-station construction, and the writer hoped that it would be appreciated and followed for the average industrial boiler plant of the future.

---

[1] National Tube Company, Pittsburgh, Pa.

N. G. Reinicker[1], while admitting that the author was correct in his statements of the importance of efficiency and capacity, considered that any conclusions regarding these items, based upon the tests reported, would be entirely out of accord with results which could be and were being obtained with similar equipment and coal throughout the country.

The fact that the runs were of only eight hours' duration was sufficient alone to discard all the tests. With any furnace having a large amount of fuel on the grate, as was the case with the underfeed stoker, it was possible in an 8-hr. test to get any efficiency desired. Twenty-four hours was the minimum time in which such runs should be made.

In every test reported there was a large deficiency of air. The furnace was apparently used as a gas producer, with secondary combustion in some of the passes, as shown by the exit gas temperatures and CO loss, and undoubtedly considerable smoke came from the stack.

The drafts for all runs showed no consistency, especially furnace draft, which was much higher than necessary. The air pressure under the tuyeres should have been from $\frac{1}{4}$ in. to 1 in. higher to supply the required air to burn the coal.

Assuming the tests were greater in number, more carefully run, and representative of the equipment and coal used, the conclusions reached from an analysis of the Combined Boiler-Unit Operation Chart would be of no value to an operating man. The experience of trying to pick from a chart the air pressure required for any rate of burning coal was like the experience gained by a number of engineers who bought tachometers for their stokers and had a second scale added showing the air pressure the fireman should carry for that stoker speed. They found the second scale of no value.

The author failed to mention the most important item controlling capacity and efficiency in an underfeed-stoker furnace, and that was the temperature at which the ash fused. With a coal causing considerable clinker, air quantity would not affect capacity unless the air could be made to distribute through the fuel bed, and not through holes in the fire. Clinker would cause holes and would limit capacity and reduce efficiency.

Less attention should be paid to convection and radiation, the losses from these items being such a small part of the total losses in a boiler-and-furnace heat balance, and much more attention paid to losses from combustible in the ash and from CO, which losses together, using the equipment and coal of these tests, should not be more than 10 per cent of the total heat supplied.

C. F. Hirschfeld wrote that there were three distinct subjects treated in the paper and they should be recognized as such and separately considered. These subjects were:

1 A discussion of the combustion of solid fuel on chain grates and on underfeed stokers, with a suggestion as to the essential variables and means for their indication and control
2 A discussion of the factors influencing the efficiency of the boiling vessel
3 A demonstration of the fact that the efficiency of the furnace as a heat liberator and the efficiency of the boiling vessel as a heat absorber were interrelated, and that there was one set of furnace conditions at each load which gave the best efficiency for the combination.

With reference to the discussion of combustion and its control, there had been a very general recognition recently of the fact that the burning of coal under steam boilers could be reduced to a fairly exact procedure if the proper indicating instruments were supplied. It had also been recognized that if the best results were to be obtained it would not be sufficient to supply only instruments by means of which the operator might measure the degree of success achieved. It was also necessary to furnish instruments which would measure for the operator the values of the various variables which combined to give the indicated result in order that he might be able to change the values of these variables wisely and methodically for the purpose of obtaining the highest possible effect.

The author proposed thickness of fuel bed and pressure drop through the fuel bed as the important controlling variables. He further proposed an inferential method of determining fuel-bed thickness, namely, the measurement of the quantity of air passing through the fuel bed in a given time and the pressure drop required to force this quantity of air through the bed.

If the operation were to be conducted by men of such mental caliber that they could not be educated beyond the point required to enable them to keep the indications of two instruments at prescribed points, it would be admitted that the author's suggested method of furnace control would probably give as satisfactory average results as could be obtained under those conditions. However, it might be pointed out that it represented little if any advance over the automatic interlock between fan speed and stoker speed, originally a characteristic part of a Taylor-stoker installation.

If the operation were to be conducted by men of such mental caliber that they could be educated to a true appreciation of the meaning of all, or most, of the variables which interacted to give a certain result in the furnace, then the proposed method would be decidedly inadequate and imperfect, particularly as applied to underfeed stokers. In this case the pressure drop through the bed, taken in conjunction with the quantity of air passing, would be a true indication of the average thickness of the fuel bed if that bed were always formed of coal of the same kind and size, if the damper settings on extension grates and other controllable points were always the same and if the character of the fire as influenced by its past history were always the same. Unfortunately, all of these variables had marked effects.

To take extreme illustrations, it might be assumed, for one case, that an operator had managed to pile up a thick fire at the top of the stoker and had burned it very thin toward the toe; and for another case, that he had forwarded the fuel more rapidly than he should have, so that he had a thin fuel bed near the top of the stoker and a thick fuel bed near the toe. In each case he would have obtained and observed some definite pressure drop which would have corresponded to perfect fires of certain definite thicknesses, and yet his fire would have been far from perfect. Or again, it might be assumed that the character of the coal and its method of combustion were such that there was serious clinkering in spots, with burning through in others. Such a condition would give a pressure drop corresponding to some definite thickness of perfect fuel bed, and yet the actual conditions would be far different.

After all was said and done, optical inspection of the fire and a good knowledge of its past history were required if the best results were to be obtained. The combination of such inspection and such knowledge with the readings of properly chosen instruments, by an operator educated to the point where he could appreciate the true significance of all facts and indications, was the most promising method of obtaining high efficiencies.

The firing methods in use in the boiler rooms of The Detroit

[1] New York Edison Company, New York.

Edison Company practically included the features which the author proposed, but others had been added and it was recognized that more must be added before the best control now in sight could be attained. At the plants of this company it was customary to maintain a certain definite draft at a chosen point above the fire and to vary the under fire pressure to suit conditions. This arrangement gave the fireman a measure of the pressure drop through the fire. The quantity of air used was not measured in conventional units but in terms of blower speed and resistance through the bed, which was just as good a combination measurement, so far as the operation was concerned.

No attempt to reduce coordinated readings to chart form had been made because the constant effort of the engineers had been devoted to the education of the men to such a point that they could reason from the known condition of their fire and the readings of their instruments, instead of going it blind on the basis of charts which at best could represent only average conditions.

In these plants it had been found advisable to supply instruments for indicating stoker speed, carbon-dioxide content of flue gases, temperature of flue gases and boiler output, as well as the values mentioned above, and it had also been found advisable to supply numerous dampers for controlling the distribution of air to the various parts of the fire. With all of these tools in the hands of thinking operators, remarkably good results were obtained and maintained.

The author of the paper had performed a real service in emphasizing, in what had been previously referred to as the second and third parts of his paper, the known fact that the best overall efficiency of the unit was really the product of the efficiencies of its two component parts and that the best combined efficiency might not correspond to the highest efficiency of furnace or of boiler. There were astoundingly few figures available by means of which one might even approximately determine values of this sort, and it would be of great value to the industry if typical units could be tested over wide ranges with respect to all essential variables in about the same way as had been the unit tested by the author of the paper.

Unfortunately for the type of control advocated, and for the worth of the data submitted, the tests recorded in the paper did not seem to represent good furnace practice. The so-called overall efficiencies were low, even for modern operating conditions under variable loads, and were correspondingly lower in comparison with what would be expected under test conditions.

Moreover, when these efficiencies were considered in conjunction with the stated thickness of fire and the under-fire pressure, one was driven to the conclusion that what the author called a thin fire must really be thick and what he called a medium fire must be very thick, or else that some other variable of great importance must have been neglected. The flue-gas temperatures and carbon in refuse also appeared to be abnormally high for the various loads and conditions to which they corresponded.

MR. KREISINGER PRESENTS PAPER BY HIMSELF AND MR. BARKLEY

With President Hollis again in the chair, a paper entitled Radiation Error in Measuring Temperature of Gases, by Henry Kreisinger and J. F. Barkley, was then presented by the former.

The purport of this paper was that in measuring a temperature of a stream of hot gases surrounded by colder or hotter surfaces, heat radiates to or from the measuring instrument, making it read high or low, and the difference between the true temperature of the gases and that indicated by the instrument is called the radiation error.

The paper enumerated the factors with which this error varies, and to show the magnitude of the effects of some of them, gave results of a series of measurements made with thermocouples placed at different points along the paths of gases flowing through water-tube boilers, citing one instance where the error under certain conditions could be as much as 320 deg. cent.

A written discussion of this paper was contributed by E. A. Fessenden and R. B. Fehr, who wrote that the paper was of decided value in calling attention to a source of error that had heretofore been almost universally neglected. It was, of course, obvious that there was no radiation error where the temperature-measuring device was completely surrounded by surfaces at the same temperature as the medium whose temperature was being measured. Many experiments concerning gas temperatures in steam boilers, however, had failed to be of material value because the conclusions had been based upon direct temperature measurements of gases surrounded by comparatively cool surfaces.

It was stated in the paper that "very likely it is the extent of the surface of the hot junction which determines the magnitude of the radiation error." It was not clear, however, just what was meant by "the surface of the hot junction." Apparently the authors had taken this to mean the surface of a cylinder whose diameter was that of the junction, which in their case was made the same as the diameter of the elements. No mention was made, however, of the length of this cylinder, and the surfaces had been assumed to be proportional to the diameters. The effects of conduction along the elements from the couple ought to be discussed along with these radiation effects. It would seem, therefore, that the length of the cylindrical surface as well as the diameter should be considered on account of the effect of the conduction of heat to or from the hot junction. Three cases might be noted:

1 Where the couple leads were surrounded by material of the same temperature as the junction (as, for example, in the authors' experiments in which the couple leads were perpendicular to the direction of flow of a large volume of gases) the temperature of the leads was the same as that of the junction and no conduction effects were produced.

2 Where the couple leads were surrounded by material cooler than at the junction, the temperature of the leads would be lower than that of the junction so that heat would be conducted away from the junction by the leads. The amount of heat carried away from the junction in this manner, and consequently the lowering of the junction temperature, would depend upon the material of the leads, their cross-section, and the temperature gradient. An example of this condition was the case where the couple was inserted in a boiler tube in which the gases were flowing parallel to the couple leads and with the hot junction pointing upstream.

3 This case was similar to the second one except that the material surrounding the leads was hotter than at the junction, as when a thermocouple in a boiler tube pointed downstream. Here heat would flow toward the junction and tend to raise its temperature.

In the second case radiation to cooler surrounding surfaces and conduction along the elements both tended to make the

reading lower than the actual temperature of the substance, while in the third case conduction tended to raise the reading and radiation to lower it.

It was to be hoped that this paper might be considered as preliminary, and that the authors would continue these investigations and at a later date give definite and quantitative information as to the effects of radiation and conduction upon thermocouples, taking into account:

a Size and material of couple elements
b Size of lead at hot junction
c Length of exposed elements
d Size and kind of protecting tubes
e Application of Stefan-Boltzmann law
f Temperature gradient in the substance surrounding the leads.

MR. KREISINGER'S REPLY TO THE DISCUSSION

Henry Kreisinger, in his written closure, replied to the suggestion of Messrs. Fessenden and Fehr that the effects of conduction along the elements of the couples should have been discussed along with radiation effects, saying that this point was simply a question of how complete a treatise on the errors in measuring the temperature of gases one wished to write. The authors had decided to treat the radiation error, and had limited themselves in the present paper to this error as far as practicable. The thermocouples they had used in their experimental work were so constructed and the experiments so planned that the conduction effect was eliminated.

In all cases the leads from the hot junctions were sufficiently long as compared to their cross-section that any lowering of the temperature of the hot junctions by heat conduction along these leads was prevented. With the smallest couples the leads were 0.008 in. diameter for a length of 1/2 in., and then 0.025 in. diameter for a length of 3/4 in. The cross-sections of these leads were too small for heat to be conducted along their lengths. Within the lengths of these leads the temperature gradient of the gases could be but very small. This construction of the couples was very well adapted to the measuring of temperature of gases within a boiler tube, as cited in the second case noted by Messrs. Fessenden and Fehr.

The large copper-constantan couples were made of copper tubing 1/2 in. in diameter, having a wall 0.052 in. thick. This tube which formed the leads was immersed in the gases for a length of about four feet. The temperature gradient for a large part of this length was very small, so that it was not necessary to consider the conduction of heat from the hot junction along the leads. The same could be said as to conduction of heat along the protecting silica tube of the large platinum thermocouples.

The surface of the hot junction of the small couples might be considered as cylinder, but in the large couple this surface was partly a sphere and partly a cylinder. Just how much of each should be considered was difficult to determine. The particular construction of the large couple was adopted because it was simple and inexpensive, and mainly because commercial thermocouples were of a similar design.

It should be added that the hot junctions of all the couples were placed in the center of the stream of gases and pulled out by steps, temperature readings being taken every two inches to determine temperature gradient of gases. The results of this part of the experiments were given in detail in the Bureau of Mines publication on Measuring the Temperature of Gases inside of Boiler Settings.

The fact that the radiation error became smaller as the diameter of the couple decreased, might be explained without going into too detailed refinements in the following manner: The couple received heat from the gases by convection and gave it off by radiation. When the temperature of the couple was constant the quantity of heat received by the couple was equal to the quantity given off by radiation. The convection did not impart the heat directly to the metal of the couple but to the outside surface of a gas film adhering to the solid. Through this gas film the heat passed by conduction. On the other hand, the heat was radiated directly from the surface of the metal through the layer of gas.

The quantity of heat that was received or given off by the couple depended on temperature difference and the extent of the surface receiving or giving off the heat. Since the thickness δ of the gas film remained practically constant no matter what the diameter of the couple was, it was apparent that as the diameter of the couple decreased the heat-radiating surface decreased faster than the heat-receiving surface of the gas film. The effect of the unequal decrease of the two surfaces was especially marked when the diameter of the couple became less than the thickness of the gas film. As the zero diameter of the couple was approached the ratio of the heat-receiving surface to the radiating surface became infinitely large, the radiation ceased and the temperature of the couple became the same as the temperature of the gases.

Following this course of reasoning, it was possible to apply the Stefan-Boltzmann radiation law and the law governing the heat transmission by convection and derive an equation expressing the relation between the diameter of a couple and the true temperature of the gases when the temperature of the surrounding surfaces and the temperature of the couple were given. The temperature of the couple was read when the quantity of heat received by convection was equal to the quantity given off by radiation; or, if Hc designated the heat received, and Hr the heat given off,

$$Hc = Hr \ldots\ldots\ldots\ldots [1]$$

Let T = the temperature of the stream of gases
T_3 = the temperature of the outside surface of the gas film adhering to the couple
T_1 = the temperature of the couple
T_2 = the average temperature of the surfaces surrounding the stream of gases, expressing all temperature in absolute units
S = the surface of the gas film receiving heat by convection
S_1 = the surface of the metal giving off heat by radiation.

Then from the law of heat transmission by convection,

$$Hc = K(T - T_3)S \ldots\ldots\ldots\ldots [2]$$

Inasmuch as with a set of any number of couples the velocity and density of gases were the same for all couples, these two factors were embodied in the constant K. And from the Stefan-Boltzmann law,

$$Hr = r(T_1^4 - T_2^4)S_1 \ldots\ldots\ldots\ldots [3]$$

From equation [1],

$$K(T - T_3)S = r(T_1^4 - T_2^4)S_1 \ldots\ldots\ldots\ldots [4]$$

The same quantity of heat that was imparted to a unit of the outside surface of the gas film by convection, passed through the film by conduction and might be expressed by the simple equation:

$$H = C\ (T_3 - T_1) \ldots\ldots\ldots\ldots [5]$$

therefore $C\ (T_3 - T_1) = K\ (T - T_3) \ldots\ldots\ldots\ldots [6]$

or $T_3 - T_1 = (K/C)\ (T - T_3)$.

But $T - T_1 = (T - T_3) + (T_3 - T_1) \ldots\ldots\ldots\ldots [7]$

or $T - T_1 = (T - T_3) + (K/C)(T - T_3) = k(T - T_3)$.

Therefore, for the whole couple,

$$H_c = c(T_1 - T_2)S \ldots\ldots\ldots\ldots [8]$$

Taking D as the diameter of the couple, then:

$$S = \pi D, \text{ and } S = \pi(D + 2\delta).$$

Equation [ ] would then become

$$C(T_1 - T_2)(D + 2\delta) = (T_2^4 - T_3^4)D \ldots\ldots\ldots [9]$$

where C embodied all the constants.

It should be remembered that the constant C' embodied the convection constant, which was affected by the velocity and the density of gases, and radiation constant, which was affected by the condition of exposure of the couple. So when any one of these factors changed the constant must be changed also. It was also probable that the thickness of the gas film changed with the velocity of gases passing the couple. However, the data availing did not justify more detailed analysis of the equation. On account of the fourth-power variable, the equation was rather cumbersome to work with. The work could be made somewhat easier by making T_2 equal to one and expressing the other temperatures as ratios of T_2, remembering what this provisional unit was and changing the final results into the standard units. Such substitution of units eliminated one fourth-power factor.

Using this method of arbitrary temperature units, and $2\delta = 0.08$ in. and $C' = 3.9$, the equation fitted the curves A and B of Fig. 6 of the paper. The readings for both of these curves were taken under the same conditions of exposure and about the same velocity of gases.

For curve R the conditions of exposure and the velocity of gases were entirely different, so the constant C' must be changed. If the constant was made equal to 12, the equation would fit the curve R. The value of $C' = 10.8$ satisfied the curve M.

SCIENTIFIC METHODS OF MANAGEMENT PRESENTED BY MR. THOMPSON

A comprehensive paper entitled Development of Scientific Methods of Management in a Manufacturing Plant, by Sanford E. Thompson and his associates, was then presented by Mr. Thompson. During the presentation of this paper and discussion, President Hollis relinquished the chair to Mr. Max Toltz, Manager of the Society. A summary of the paper follows:

The authors present in considerable detail the outline of the development of scientific methods as applied to the ordinary manufacturing plant. To make this a more concrete illustration, the discussion is centered in the plants known as the Eastern Manufacturing Company, at Bangor and Lincoln, Maine, one of the largest concerns in the country manufacturing writing paper as its final product. The development of scientific methods at these mills, however, is not, as one might assume, descriptive of a simple and comparatively localized industry. As a matter of fact, the processes involved in pulp and paper making are similar in type, so far as management methods—not in specific technique—are concerned, to a vast number of industries.

The paper was discussed orally by Frank B. Gilbreth, who illustrated his remarks with lantern slides, W. H. Carrier, Max Toltz, Calvin W. Rice and Harrington Emerson.

Frank B. Gilbreth said that he wanted to call attention to the relation of the address on the previous evening by President Hollis to the subject of Mr. Thompson's most admirable paper. He was tremendously impressed by Mr. Thompson's talk, because he had been in Europe several times since the war began, and it was no exaggeration to say that millions of our boys would be on the battlefields after the war was over. We could not help that, but we could help the waste that was going on in this country at the present time, and the waste that would continue to go on after the war. From this standpoint he wished to take great exceptions to Mr. Thompson's admirable paper in that he followed out the procedure of his predecessors in giving the impression that there were such things as elementary units in stop watch time study, and that the data obtained from such study were accurate, transferable and of permanent value.

He wanted to call attention to the fact that the Society could not go very far in utilizing data unless they were in such form that they were usable by all the members. Stop watch time study is inaccurate, through the fact that the variable of the human element is involved in pressing the stop watch. It is not transferable, in that it does not provide for recording the surrounding conditions under which the observed activity takes place. For these two reasons, among others, it lacks permanent value.

It is possible to obtain accurate records of activity that include not only the time taken by the activity, but by the elementary units of which it is composed, through methods that are inexpensive, available and adequate. Through the use of the micromotion method and the cyclegraph method, which he illustrated by lantern slides, it is possible to obtain data that are so complete and so accurate that they are usable at any time by any person. From these data may be obtained charts that enable one to transfer the facts obtained not only from one activity to another, but from one type of worker to another who has an entirely different mental, physical, or material equipment.[1]

The special importance of these facts at this time is their relation to waste elimination. If we are to do our part in the savings that are today so necessary, we must begin to collect our data in a more economical fashion, and to put them into such shape that they may be universally useful in the shortest amount of time possible. We would, therefore, urge such men as Mr. Thompson, who has both the natural ability and the training that lead to expertness in observing and recording data, to discard inaccurate devices and to insure that the results of their valuable investigations are both immediately and permanently usable.

W. H. Carrier said that it seemed rather remarkable that time study as related to efficiency as a whole from a scientific and from a manufacturing standpoint had progressed so little in the paper-making art in the last number of years as compared with other arts in this country, particularly with reference to the work in the machine room. He was not a paper-mill man, but had been connected with problems in paper mills where the lack of manufacturing efficiency in the art of paper production had been most striking.

It had been determined by several different observers for instance, that in the process of the machine room in the drawing of the paper from 30 to 50 per cent of the possible strength of the paper was lost; and that the cost of producing paper of a standard as high as writing paper was nearly double what it might be if improved methods were introduced and studies made.

Even at the present date it had been shown by actual tests to be possible either to increase the strength of the paper or decrease the cost of a given standard from 5 to 15 per cent by

[1] See Motion Study for the Crippled Soldier, Jour.Am.Soc.M.E., December, 1915.

the use of improved methods, and at the same time to increase the output 10 to 20 per cent by the use of improvements in drying, particularly the application of air and the proper handling of the rolls.

Comparatively few machine rooms were being provided with improved machinery, although their number was increasing. But there should be a thorough study made of the possibilities which would result, he was certain, in a practical revolution of the process of paper making by machinery.

Calvin W. Rice asked what proportion of the value of the product of a paper mill the cost of counting of the sheets represented. He asked whether the product had now been developed to such a uniformity that the number of sheets could be arrived at by weighing them, and if not, whether other processes had been found which would avoid the expense of counting.

Harrington Emerson said that some seven years ago he was engaged to standardize the work in a paper mill very similar in size to one described in the paper. He went through all the departments and standardized the work. There were at least 3500 different varieties of paper, and he was not certain but what there were 35,000. A great deal of work done there would have been very useful to Mr. Thompson at the beginning of his studies, and with it he would undoubtedly have extended the studies already made.

This is mentioned because Mr. Emerson feels that he also is duplicating work already more thoroughly done by Mr. Thompson and others, and he regrets that there is no available clearing house of experiences.

As an evidence of the thoroughness with which some of the work was done, he would say that the plant in question was the only place in the world that he knew of in which labor costs were immediately and accurately so distributed that in nine months they were not one mill out in the distribution of the work of 600 or 700 men, and the record was complete at 10 a. m. of the day following. The work was performed by three girls, one of whom was a substitute.

CLOSURE BY MR. THOMPSON

Sanford E. Thompson replied to Mr. Rice that sheets still had to be counted. We had not reached the point where we could accurately determine the count by the weight. The cost of counting, however, using the rubber finger tip, is small and is useful in separating small lots.

He considered that Mr. Carrier was too low in his percentages of possible cost reduction. There was a chance for an appreciable increase in production and improvement in quality by radical changes in machinery, not only in the paper machine but also in the beating engines, and these problems were now being studied in the mills referred to in the paper. They were still using in all paper mills the Hollander beating engine that was invented not less than fifty years ago.

Mr. Gilbreth was correct in his statement that time study was capable of further standardization, and we had gone only a very short way in the developing of standard methods of taking time and in getting these methods so that the results of different operators would be comparable. He was not yet quite ready to say, however, that Mr. Gilbreth had the plan that would entirely revolutionize the taking of times. At the same time, the general principle of getting with his pictures, as he did, the methods of doing the work was of considerable value in many cases; and there was no question, even in his mind, that often that might be vital interest, and should be applied.

MR. WEAVER'S PAPER PRESENTED BY TITLE

The fifth and last paper of the session, on Disk-Wheel Stress Determination, by S. H. Weaver, was presented by title only, and will be published in full in the Transactions of the Society.

JOINT SESSION WITH MACHINE TOOL BUILDERS, TUESDAY AFTERNOON

A JOINT Session of The American Society of Mechanical Engineers and the National Machine Tool Builders' Association was called to order by President Hollis of the former Society. An audience numbering 400 of the members of the two organizations was present.

The Chairman, in opening the session, expressed the high satisfaction on the part of the two societies with this joint meeting, which he hoped was only the beginning of many such meetings, since the two associations belonged very much together and could work together very effectively.

The Chairman introduced Mr. James Hartness, who presented resolutions of appreciation and condolence on the death of Mr. William Lodge, President of the Lodge and Shipley Machine Tool Company, of Cincinnati, a member of The American Society of Mechanical Engineers for 27 years, and one of the organizers of the National Machine Tool Builders' Association and its president for two years.

Dean Herman Schneider, College of Engineering, University of Cincinnati, was then introduced and delivered an interesting and forceful illustrated address upon the subject of The Trend in Engineering Training. Dean Schneider's address will be given in full in a subsequent issue; the purport of this paper is conveyed by the following paragraphs:

THE TREND IN ENGINEERING TRAINING

"It is interesting to note that prior to fifteen years ago convention programs dealt almost exclusively with materials and the natural laws governing them. About fifteen years ago, however, there began to appear some papers on organization, which was then becoming a pressing problem. More recently we have been accustomed in conventions to a new phrase, 'the human element in industry.' These three are the great divisions of production: materials, organization, and men.

"Courses of study in engineering colleges have followed the needs expressed in conventions, so that necessarily, in the early days, the courses of study for engineers dealt almost exclusively with materials and their laws, and the engineering colleges straightway attempted the solution of the problem of materials. There grew up college laboratories wherein materials could be analyzed and the laws governing them ascertained.

"A little later, when engineers began to take up the problem of production so far as organization was concerned, the colleges introduced courses in organization. None of those courses is as yet satisfactory, however, for there are no laboratories available in the universities for the study of organization, which must, therefore, be made from books.

More recently, with engineers [illegible] the pressing problem was what was called 'the human element in production,' the colleges became confronted with the problem of ascertaining some sort of relation which would give a fairly equal and just measure of interest and study in the three elements of materials, organization, and men.

"The trend of engineering training indicates that there will be three types of attempts made to solve these problems so far as engineering schools are concerned. First, there will be the attempt that has been made in some colleges not to conduct a great laboratory, but to confine a large part of the study to books. We have that kind of college in evidence in the study, for example, of organization exclusively from books. That type of American college will attempt also the study of the man problem out of books; in other words the sequestered method, the withdrawing of men from contact with industry in order to study industry, will prevail in some colleges. There will be the same trend in the study of organization and men that has prevailed in the study of materials.

"In the second place, there is a movement, inaugurated by the Massachusetts Institute of Technology, whereby arrangements are made with manufacturing concerns to have in those concerns laboratories and classrooms for the students of the Institute. In the later years of the course, according to that program, these young men are taken from the university and go, so to speak, to a secondary school—an accessory school—at some manufacturing plant where they observe the work done and after classes are instructed in the manner of doing the work.

"The Massachusetts Institute of Technology has made arrangements with a number of organizations, such as cement companies, chemical companies, and so on, for those students at the present time who are studying chemical engineering, whereby classrooms are put in the building in or near the plant, and the students go to the classes, and then go out into the shops to observe the work done in the actual commercial department of that particular concern. They spend a year in this. You can see that that scheme is possible of enlargement, and it offers a splendid opportunity for the study, at fairly close hand, of the three elements of production—materials, organization and men.

"The third attempt is one which has been inaugurated at the University of Cincinnati, and is known as 'the coöperative' system. In this system a plunge is made straight into the industry. The young men are sent out right at once upon entering their course into the work of the industries. They are not sent into classrooms there, but are sent out to do actual work and become part of the organization. They start at the very bottom. The civil engineer starts with a pick and shovel; the mechanical engineer starts in the factory or machine shop as a helper; the electrical engineer starts in the machine shop on electrical work, and so on."

Dean Schneider then exhibited a number of lantern slides exemplifying the main difference between the three types. He concluded:

"The first type is easy to operate because the whole field of operation is within the scope of the men who operate it.

"The second type is a little more difficult, because the school has to deal with different concerns, and arrangements have to be made so that there is no confusion in the work.

"The third type, the coöperative system, is extremely difficult of operation, for the problems are those that arise in the shops in addition to those in the University.

"The men operating the coöperative system are confronted daily with the same problems that the manufacturers have to meet, because their young men are working in the manufacturing concerns and become part of the problem.

"The University has had to cope with very peculiar conditions, looking at the problem from the industrial and educational point of view of the man who works and the man who employs; because the young men are working, they are working men governed by rules. At the same time the University is concerned with the major problem, the big problem of engineering and of efficient and economic production, so that the University authorities governing that course have to meet these vexing problems right along.

"The difficulty of operation is about the only thing in the way of the adoption of the coöperative plan, outside of any question that may arise as to the fundamental philosophy of the work itself. The differences that arise as to the value of this kind of work are very proper."

W. F. M. Goss said that all who had been concerned with the problems of technical education had looked with great interest upon the coöperative undertakings of Cincinnati University. These undertakings represented a procedure which was practicable only in a few communities, so that in considering their merits one was forced early to recognize this limitation. This statement emphasized the fact that the University of Cincinnati was to be congratulated not only upon the possession of Dr. Schneider, but also upon the wonderful environment which the peculiar activities of the city of Cincinnati supplied. The coöperative plan in techincal education as developed by Dr. Schneider was, he took it, a logical adaptation of means to an end. Through its adoption a great work in education had been and was being accomplished. It was to this fact that he especially wished to bear testimony. He wanted also to express to Dr. Schneider the pleasure and satisfaction he had had in listening to his masterful presentation.

Frederick W. Putnam said he had come to Cincinnati to study the coöperative system in the high schools, and found that he had also a chance to study the same system in the University. It seemed to him that the people in that city owed a tremendous debt not only to Dean Schneider, but to the Superintendent of Public Schools.

He believed that in his own city, Providence, their problem was working out and they were going to have the hearty coöperation of the manufacturers, including Mr. Luther D. Burlingame, of the Brown & Sharpe Mfg. Co., Mr. Arthur H. Annan, of the Rhode Island Tool Co., and Mr. D. M. Bartlett, of the Builders' Iron Foundry, all of whom had spent money on their undertaking. He thought that all of the success they had made was due largely to the fact that the manufacturers were interested, and that they wanted the boys to have a chance. They were trying to see that they got a fair, square deal all the way through. He believed that when those boys were through they would have gotten a good start for the active business of life because of the honest and sincere coöperation on the part of the manufacturers of the city of Providence.

James Hartness asked for information as to how many places the coöperative course under discussion had been applied in the United States. He understood it had been put into three or four hundred high schools, and he asked whether it was not an unqualified success. He knew that in Springfield, Vt., they considered it so.

If the movement were to go forward, as he thought it should, in all or in many centers, he thought we should all know about it, so that we could carry it home, where we could

bring our interest to bear to see that such things were given to the youth of our own places.

R. Poliakoff[1] described how the practical education of the students was carried on in the Technical Institute in Moscow, Russia, which had been reorganized and put on a new basis in 1870 so as to correspond with the system at that time prevailing in the engineering schools of Germany.

At the Centennial Exposition, in 1876, the school had exhibited quite a number of specimens of the work of its students, who at that time were required to spend three or four days weekly, from six to eight hours every day, in the shops attached to the school.

Very complimentary reports had been made about the students' exhibit at the Exposition, one of them appearing in the bulletins of the United States Bureau of Education. The exhibit itself would, he believed, still be found in the machine shops of the Massachusetts Institute of Technology.

As time went on the national trend had changed, and they had begun to believe that the student must know something else in addition to shopwork—he must know more about theory. For that reason they had gradually steered away from too much work in the shops.

Some twenty years ago, when he was a student himself, three days a week in the shops on filing, chipping, turning, etc., was required, also work in shops where small steam engines, compressors, lathes, shapers, etc., were made. The students had to work in those shops just the same as the ordinary workmen, and make out reports as to the progress of their work. Since about 1905, however, those in charge of the Russian schools had begun to think that different methods should be employed, and laboratories had been organized. To give an idea as to the size of some of these, he mentioned that the textile laboratory comprised a regular textile mill, a building three stories high, and the machinery installed in it probably represented an investment of $150,000. The students were afforded there an opportunity to pass from one machine to another. The school employed a number of practical men from a factory who worked with the students, and in that way he believed they turned out very good textile engineers who could go right into a factory and start to work there. In addition to that, every student that worked in that textile industry was expected to spend two or three summers in some mill in order that he might become a good practical engineer, and so that as soon as he was graduated he would be sure of finding a position.

In regard to machine-shop practice, the system at the Institute was a little different. They had still some shops which had not been abandoned, for instance, the practical machine shops in which various kinds of machinery were turned out. They had found out, however, that it did not pay a school to run such a shop on a commercial basis, and on the other hand they believed that only when it was run on a commercial basis could it be used as an educational institution for practical work; therefore, they simply rented the shop to a private concern, which concern ran the shop, and the students had the right of access to all the other shops of this concern, and worked in the shops under the guidance of the Institute's own engineers. The steam-engine laboratory supplied steam also to this private establishment, and, of course, it had to supply it at the proper time and in the proper quantities. The work was arranged in such a way that there was complete coördination of all the different sections.

[1] Assistant Professor of Mechanical Technology, Technical Institute, Moscow, Russia.

The students worked also for two summers, sometimes for six months every year, in the shops of private concerns outside the school. They were paid on an hourly-rate basis, and as many of them had not sufficient means to enable them to support themselves, they depended to a great extent upon these earnings, and so they attended to their work very regularly.

During the last three or four years some changes had been made in the courses, and less work was done in the school in the way of machine-shop practice and more in the private works. So, while this was of course not a coöperative system in the way that Dean Schneider operated it, he believed, there was not so much difference between the two systems. It was, after all, only a question of coördination; and they were trying to carry on their system in the best manner. Local conditions of course had to govern, and there were always variations that were suitable to special needs or localities. What might suit one might not suit another; but he thought the prevailing idea in all cases was to give the students some practical education outside of the school, leaving to the school the more theoretical part of their education.

Calvin W. Rice said he was hopeful that the Society and the National Machine Tool Builders' Association would some day follow the lead of the other professional societies of the world in having a committee on engineering education. The professional societies of other countries had felt it an obligation to establish a relation between the teaching of engineering and the work of the societies. He did not know of any such definite relation in America between the professional societies and the colleges, and he thought that there should be a definite relation. He was hopeful that as an aftermath of this address some members of our Society would volunteer to make a sacrifice of time and study, and develop a committee to so correlate the teaching of engineering that the students when they were graduated would be acceptable to the profession and to the industries.

E. F. Du Brul, who has taken an active part in interesting manufacturers of Cincinnati in Dean Schneider's coöperative plan, said the main difficulty encountered in conducting the coöperative course lay in procuring practical teachers of commercial experience who were willing and competent to teach engineering students at work in the industries every alternate two weeks. Not every technical college professor was willing to teach at the college eleven months a year, instead of the usual nine months. In fact, some of the men must even be content with only two weeks' vacation.

Mr. Du Brul said that it took a number of years to overcome academic inertia in Cincinnati, where conditions made that inertia less than it probably would be anywhere else. But now the manufacturers of Cincinnati who employed, paid and trained these students were getting results from them eminently more satisfactory than they ever got, or could get from the ordinary type of engineering student who comes in a factory after graduation.

There were now 500 students enrolled in the engineering college, and the only industrial difficulty was that the college had no room for more. From 3000 to 4000 applications were received every year, from which only about 200 could be accepted.

Mr. Du Brul stated that a manager of a large concern recently wrote Dean Schneider, stating that he had read a magazine article about the coöperative course and would like to try six graduates. He said that his company would pay them $60.00 per month the first year, $75.00 the second year

and $100.00 the third year, and whatever they were worth thereafter. It was fair to assume that later salaries would be $110.00 to $120.00 per month during the fourth year.

Dean Schneider replied that he could not supply any of his graduates under those conditions, because firms that were employing the students were paying them for the time they worked on an average basis of $90.00 to $100.00 per month during their last terms in college, and that such firms found these men so valuable that their salaries at the end of the third year after graduation averaged about $3000.00 per year. "Is the average graduate of the average technical college," he asked, "worth $3000.00 a year at the end of his third year after graduation?"

Some educators to whom this question had been put very bitterly charged that this was putting education on a sordid commercial basis, saying that a money standard should not be applied to measure the value of an engineering education. To this the speaker said he had replied that a laborer was worthy of his hire, and that since most engineers ultimately earn their living in commercial establishments, the salary an engineer could draw was a fair measure of his worth to his employer. If therefore, the average graduate of the coöperative course appeared to be worth more to the users of trained men than was the average graduate of the traditional course, the commercial standard proved the coöperative course to be the better course, both commercially and educationally.

It had been stated that at Providence, the manufacturers did not want to make money out of the coöperative-high-school students. In Cincinnati it was understood that, far from having any tinge of charity or tolerance, the coöperative course in the University did return a direct and immediate profit to all concerned. The Cincinnati manufacturers were not unfairly exploiting the students, but were making money by employing them, just as they did by employing any other employees.

Mr. Du Brul concluded with the statement that the plan was truly coöperative. The employers made a direct profit on the regular output of the students and they made a larger though intangible profit by training those students to be the sort of engineers that they required in the industries. The students profited directly because a great majority of them could not procure an engineering education, due to the lack of funds, without some plan that helped them to pay a large part of their expenses. They had a further profit in the opportunity to secure an engineering education of a kind that fitted them to hold a better job than they could otherwise get after graduation. The University profited directly in that, being very limited in its funds, the Schneider plan enabled it to educate more and better engineers for the amount available, at a lower cost per head than any other institution could show under the traditional plan. The University's indirect gain was the great reputation that this plan had made for the College and its educational product in a very short time.

Dean Schneider, in his closure, answered all the points brought up by the several discussers, enumerating the institutions which were using the coöperative plan and reciting their experiences. His closure will be published with his full address.

Dr. Otto P. Geier then delivered an address on The Human Potential in Industry, which is published in full below.

THE HUMAN POTENTIAL IN INDUSTRY

By DR. OTTO P. GEIER,[1] CINCINNATI, O.

FOR the past three years history has been writing the terrible story of the human potential in modern war. As a result of a long period of peace, we Americans had looked upon war as a most remote possibility, attested to most strikingly by our present state of utter unpreparedness. As we reflect, it appears now we were not measuring nations by their fighting strength, but rather by their social, industrial and commercial strength. Nations were tabulated for their rate of production and consumption. This differential had its social as well as its economic effect. It produced state and private wealth. It produced leisure, the arts, extended educational and health measures, and raised the standard of living. In brief, the world was in keen competition not only in business life, but in social life. Nations were striving to outdo each other in promoting financial success, health and happiness for their people. Individualism had reached its zenith and the philosophy of collectivism was just appearing above the horizon.

It was rather our subconscious minds that recognized the great sea power of England and the militaristic spirit of Germany. Our real attention was focused, not on the plans and intrigues of governments, but rather on the national characteristics of their peoples. We thought of London as the financial center of the world, of the Englishman as the world traveler, a lover of outdoor life and sports, an educated gentleman and judge of the fine arts.

When we traveled in Germany we admired her order and cleanliness, her *Gemüthlichkeit*. The world paid homage to her philosophers, revered her musicians, studied and copied her educational systems and longed for her thoroughness and scientific capacity.

POTENTIAL OF WAR

But the bloody struggle of the past two years has changed our viewpoint of these nations. War, with all its horrors, its terrors, has changed these peoples. The human potential of nations is no longer directed at the creation of comforts, contentment and health, but the backs are bending low under the struggle of destruction of property and life. National efficiency is now expressed in new terms.

Shortly after the program for the Spring Meeting of this Society began to take form, our country entered the war. There were those who doubted the advisability of holding the meeting. Our fearful unpreparedness produced a public state of mind akin to hysteria. We have scarcely had our sober, serious second thought. Democracy is being subjected to the acid test. There are few so daring as to prophesy what failures and what successes we shall find. Of one thing we see signs. Our nation is finding itself. We are trying to forget and forgive ourselves for our "spread eagle" and forget our jingoism. Even in the early stages of preparedness we are intensively appreciating, as never before, the stuff that other nations are made of. Their capacity to produce, their silent ability to suffer, sets us to wonder.

[1] Cincinnati Milling Machine Company.

AMERICA REBORN

Perhaps, for the first time since the Civil War, we are thinking together. Our national consciousness has been reborn. The pettiness in us is disappearing and true Americanism is coming to the foreground. Our faces are turned to the common enemy. We have turned our backs on the paltry bickerings of the past. We are witnessing the first truce in the century-old strife between labor and capital.

This is a day that calls for statesmen as well as soldiers, for calmness as well as courage, for patience and patriotism, for virtue and vigor, for faith and faithfulness, for health as well as willingness to die. This day calls for social reconstruction as well as enemy destruction. Huge is the task in which *all* should find a place to do with all their hearts.

POTENTIAL OF INDUSTRY THE POTENTIAL OF THE NATIONS

And what tasks has our entering the war brought to industry? Huge production? Yes! But is that all? Have not old truths as to the value of the conservation of labor taken new form, new emphasis? Has not The Human Potential in Industry in the nations abroad finally been the measure of their potential on the battlefield? Has the interdependence of man ever been more fully demonstrated? Has the mutual dependence of labor and capital ever been so strikingly proved? Have we ever witnessed such limitless industrial energy and output? Has it occurred to all of us Americans, that Europe's industrial experience of the past three years holds not only a lesson but a warning? Militant and efficiently industrial England of war times will be succeeded by industrially militant England of peace times. Labor and capital in England, Germany and in France, having learned the mutual advantage of coöperation in war, are not likely to give up this advantage and return to the destructive internal warfare of former days.

OUR NEW COMPETITION

The question that presents itself is this: Can we keep pace with them in war, and will we keep pace industrially after the war? Can we stand this new type of competition unless we likewise enter upon the program of the new social order? Will not the programs of our National Association of Employers, chiefly defensive in the past, necessarily become socially constructive? Will not labor now have to seek leadership capable of best adjusting itself to these forward-looking steps.

FORWARD-LOOKING INDUSTRY

War has lifted the discussion of "the human potential in industry" out of the realms of philosophy and has used it as the foundation stone of a national economic policy. The Council of National Defense has appointed a committee on the conservation of the health and welfare of the worker, and in the interest of the health and productiveness of labor proposes to establish definite standards of plant operation. The human potential of the nation is needed at its maximum, for the country cannot afford the usual labor losses due to accident, disease or fatigue, and industrial poisoning.

A right-minded, forward-looking man does not wait for compulsory legislation to develop his business organization to the highest degree of efficiency. This type of man, for years, has developed not only the administrative and technical divisions of his plant, but, when most successful, has given a great deal of thought to the human equation; the giving of happiness and meting out of justice to his employees. It has been a great satisfaction to him to find an economic method of lessening the human waste due to preventable accidents and occupational diseases. He noted that a healthy, contented employee was a more productive employee, who, in turn, was a higher type of citizen, demanding a better standard of living for himself and family, better protection for his children against disease, delinquency, and crime, and higher forms of community recreation. He recognized that right in his plant he could make his best contribution to the health and well-being of the worker, and that he had found, perhaps, the most tangible basis for coöperation between himself and his employees. To him it was apparent that by intensively studying the health of his workers he was establishing some splendid new points of contact between himself and his men.

MASTER AND MAN, THEN AND NOW

Industry must find a substitute for the valuable relationship of master and man which passed with the coming of greater industrial concentration. Then the master was teacher as well as craftsman and to a large degree a substitute for our modern continuation school, manual training and coöperative university engineering course. Master and man worked elbow to elbow. The master largely molded the thought and living of the man. Then they had real personality for each other. Now, in too many instances, the pay envelope expresses the only bond between the two. The man was graduated from his apprenticeship, frequently to set up a business of his own; now, industrial concentration practically hinders the establishment of the new small unit. Then, labor took part in the making of the mechanism and conceived the full purpose of the machine which he assisted the master in building; now, his work is more repetitive and limited to single parts of a machine, whose mechanism he may not understand.

TENEMENT STRIKES, LOCKOUTS

It was but natural that in this evolutionary process of industry, capital and labor should become more estranged. They not only worked farther apart, but lived farther apart, for with industrial concentration, community life changed, and the tenement district developed. The difference in their scale of living was more evident. Industrial discontent was more readily bred. Labor and capital organized themselves to meet strife, and strikes and lockouts were the natural outgrowth.

Neither master nor man can be held accountable for these unfortunate conditions, which were but the natural consequence of industrial evolution and the consequent crowding of population in cities. So engrossed were both labor and capital in adjusting themselves to the new conditions that the estrangement of these former partners in work came on quite unnoticed.

DISTRUST OF EARLY WELFARE WORK

Some years ago industry began to recognize its social obligation. It saw the economic advantage of substituting fine, light, well-ventilated buildings for the dark, unsanitary workshops of the good old days. It was at about the same period that many abortive attempts at so-called welfare work were started, which in most instances failed to make any real contribution to the better understanding of labor and capital. This sort of welfare work was established on purely paternal-

[illegible] was imposed upon the group of workers without their desire or consent, and all too frequently furnished that for which they had no real need. The type of welfare contributed to the social and superficial requirements of the man, and overlooked the fundamental. It did not take into account the basic principle that the workman is very human, and that to get the best results out of any socializing effort you must first engage his coöperation. You must put him to work, so that he too may use his creative instincts, and enjoy with the employer the fruits of intelligent coöperative work. Welfare work of the former kind deserved failure and did fail. It was "built upon the sands" and was all too frequently washed away by the least wave of discontent among the workers. After the first strike, the returning man found the doors of the dining rooms, libraries, and club rooms closed upon him. The whole structure was weak and crumbled at the mere sign of a storm. Is it any wonder then that welfare work came into such disrepute with the worker and was so continuously and effectively used by the labor agitator?

BUILDERS OF MEN

It would indeed be a foolhardy individual who should attempt to interest the members of these organizations in that kind of welfare work. I am equally sure that most of the plants represented by this conference are already engaged in some effort to solve the great problem of human potential in industry. We are all groping our way toward finding the right method. If we can evolve a sound economic scheme for the establishment of a human-service department in industry, which day by day will pay dividends, which will reduce lost time for illness and accidents, reduce labor turnover, and quicken loyalty, we will not build up a "blockhouse" which will fall to pieces at the first sign of industrial strife. It will each day have served its purpose, secured a result worth while for itself, and will automatically, along with all other departments, be again set in motion the moment that the wheels of industry begin to turn.

I have faith in big industry. I believe that when builders of big enterprises sense their social opportunities they will also prove themselves to be builders of men. In time their widened perspective will include an active interest in national and local health problems, they will, for the sake of the men, use their good offices for better housing and transportation facilities. They will apply themselves to the great human problem of taking much of the drudgery out of work. With this new purpose in life will come a recompense which cannot be valued in mere dollars.

They will be instituting the first intelligent effort toward the alleviation of poverty and the establishment of social justice. Philanthropy and legislative effort to correct conditions have failed lamentably.

BUILD UPON HEALTH

The activities of the human-service department should be founded on intensive health work. Health is our most vital possession. The mere act of conserving the health is ennobling. Healthy bodies promote right thinking, right living, good habits, and it is upon such factors that intelligence, stability and loyalty are engendered. Unless we have these things, our employment departments, struggling with the labor turnover, our mutual-benefit societies and loan associations, our restaurants, our coöperative buying, our sanitary measures, will meet with but half of the deserved success.

ALL-DAY DISPENSARY

The point of approach to the human potential had best, therefore, be through the industrial dispensary. Under a high-grade physician it will be the great melting pot of the human experiences of men. Here the virtues and the weaknesses of the men will be most apparent. The physician will also be confessor, adviser, priest. Through him the employee may learn that it pays to be healthy, steady, and of good habits. He does not hesitate to preach the "Sober First" campaign.

An industrial dispensary, with a dental clinic as its adjunct, will advertise itself. It will come in daily contact with five per cent of the force, the equivalent of the whole force each month. To respond to all the possible services that grow out of these frequent contacts, it will require one full-time physician to every 750 employees.

The men will first use this department for their slight cuts and accidents; next they will begin to call the doctor's attention to some surgical defect with which they have been suffering.

DOUBLING WAGES

I recall the case of an Italian watchmaker with five children, whose complexion was pale and pasty. He seemed anxious to please his foreman, but his work, like his skin, remained rather pale. He had a bad record for absence and lateness. His average earnings amounted to $13.00 per week. Investigation showed that he had been suffering with hemorrhoids for twenty years and had been repeatedly advised against an operation. He had enough confidence in the plant physician to undergo the operation. As a result, his physical efficiency was raised, so that now his premium earnings are nearly as great as his weekly wages formerly were. In other words, the operation had practically doubled his wages. An inefficient man, an active candidate for the human scrap heap, one whose family had been on the poverty line for years, has been converted into a happy, productive citizen.

In an industrial all-day dispensary men will frequently learn that while they have been treated for rheumatism on the outside, they are actually suffering from broken arches. Again and again men will be found who are continually taking headache dope for headaches due either to gastric conditions or eye strain. Untold numbers of men will be found whose working capacity has been below normal; whom employers have always felt more or less sorry for and therefore did not discharge because they seemed anxious to make good, but they never quite "reached." Quite a lot of these will be found suffering with chronic intestinal toxaemia, while fully as many will be discovered whose lowered vitality has been induced by years of bad mouth hygiene, abscessed roots and pyorrhea. I am thinking just now of such a man who had been treated for rheumatism for years and who never was able to get out of the subnormal class of workers. A careful checking up showed pyorrhea of the teeth to be responsible. With six months' supervision and care, that man increased his earning capacity by nearly 100 per cent.

While speaking of mouth conditions, let me recall the case of a man who for three weeks suffered excruciating neuralgia of the face and head. He was the type of man that puts off going to a physician until the last moment. Examination showed that he had a very dirty mouth, a number of snags and some pyorrhea. X-ray showed an unerupted cuspid tooth lying horizontally, the pressure therefrom causing the pain. Twenty-four hours after the removal of this tooth, and the old snags, all pain disappeared. If the plant dentist

had been an average dentist no X-ray would have been called for and the man would, for weeks, have lost sleep and time from work, and have considerably reduced his vitality and working capacity.

In passing, we might mention one other case where the man was losing a day or two each week as a result of nausea, sleepy, draggy feeling, practically no ambition for work, and gradual loss of weight. Physical examination showed nothing unusual, except that the teeth were bad. Cleaning up the mouth and pulling out the old snags was followed by immediate improvement. The stomach trouble disappeared. In six weeks he gained seven pounds and had a new bite for work.

DIAGNOSIS NECESSARY

The plant dispensary, with the economic pressure back of it to get results, will go farther to establish a diagnosis than the family physician. It sees the financial advantage to the patient and to the company, to spend a few dollars for consultation or for X-ray. If the employee cannot pay for the consultation, the plant physician can always place his hands upon some consultant on the outside who will do the work for nothing. There is a drive behind the plant physician to get a quick result.

Too much cannot be said for physical examinations of employees. No one knows how many cases of incipient tuberculosis are present in his shop force. There are any number of men whose appetites are variable, who tire easily, but who have no cough or symptoms that would make them consult a physician; are perhaps merely irritable, and have a draggy feeling and no "pep." They attribute their weariness to the job. In so many cases of an early diagnosis of incipient tuberculosis, an enforced rest of a month or two will put these men on their feet again.

INDUSTRIAL CROSSED EYES

The development of the human potential with all of its mutual and economic advantages will not be introduced in industry where the employer does not possess some social vision. I am thinking just now of one narrow-visioned employer who was recently interviewed by someone who was anxious to gain a consensus of opinion as to the value of employees service departments. The total human equation in this particular industry, employing some 1100 men, was represented by a mutual aid to which the company contributed annually the large sum of $100 (less than nine cents per man). It was necessary for that association at their annual picnics, given for the purpose of raising money, to invite employees of a number of other smaller concerns. In other words, for the sake of a few dollars raised by inviting outsiders, this company blindly encouraged the undermining of any good feelings of fellowship that might have been encouraged among its employees by this one annual getting-together. The same employer boasted that the efficiency plan of wages greatly reduced the cost of production, returning ten dollars for each dollar put into that system.

A LOW-BROW HIGH TURNOVER

In discussing his men he spoke only of their lack of loyalty and the lack of loyalty on the part of the foremen. With an injured air he told that petitions for the unionizing of the employees had been in circulation in his shop for two weeks with the full knowledge of the foremen before he discovered that fact. The result is, he says, that the shop is fully organized and the union has his company under its thumb. It seems that it had been the custom of this company to entertain the foremen once a month with a dinner and smoker, and that one of these entertainments was held the night before the discovery of the petitions. With stupid satisfaction he said that thereafter foremen's meetings ceased. It is not surprising to note in passing that the labor turnover in this plant is 305 per month. This man who gives the whole sum of $100 toward the sole coöperative effort on the part of the men to care for themselves in times of illness loses $100,000 per year in excessive labor turnover.

If I were called upon to make a diagnosis of that employer, I would venture to say that he had an aggravated case of mental strabismus or was mentally cross-eyed. He does not realize that the sound-minded industrial procession is passing him. He does not know that the movement for the conservation of the industrial worker marks the greatest change in the attitude of society of the twentieth century, that next to the municipality the industrial corporation is the largest social unit, that as such it partakes of many of the characteristics and functions of a governmental subdivision. He does not realize that his industry is an example of one selfishly administered, and as such is a menace to the peace, prosperity and happiness not only of the members of his industrial unit, but a menace to the rest of the community members. A coldly calculating, selfish enterprise, no matter how big, engenders selfishness, distrust, envy and hate in individuals in and about it. As a by-product it manufactures class feeling, which other social agencies vainly try to counteract. Conversely, a socially organized, profitable, and farsighted business enterprise, by its very existence, continuously creating more work for more people, is not only a great financial asset to the community, but is of definite social value as well. The first grows at the expense of society which gave it life. The second is one of the taproots of society. The first produces the malcontents, the industrial hobo, the I. W. W. The second creates intelligent, contented citizenship, the only hope of a democracy.

THE PHYSICIAN IN INDUSTRY

To men who are attempting to fit their enterprises to this latter classification, to men who are seriously at work solving the problem of the human potential in industry, permit me to say, that most of them are overlooking the possibilities for service that the socially minded physician may render employers and employees. The proper place has not yet been accorded him. He has not been given an opportunity to make one for himself. It doesn't count for much if surgeons are employed in a plant to care for the injured. The surgeon is in just the same relation to a business and the employees as is the electrical repair man who replaces the fuse and looks after short-circuits. What is needed is a doctor, a combination general repair and safety engineer, to look after the human machinery, to study stresses and strains on it, to give warning of a probable breakdown, to advise easing up on the load until the human mechanism has been readjusted, to do the hundred and one things that make for comfort of mind and body.

COST OF ILLNESS TO CAPITAL AND LABOR

When we are told by investigators that only one industrial worker in five in need of a physician calls one, we may know what this shortsightedness in them is costing in lost time. We may also know what great service the industrial dispensary may render.

The loss of wages to the worker on account of preventable illness runs annually to the billion dollar mark. To the employer the loss must surely be twice that amount when we remember what a large part bad health plays in inefficiency, in irregularity of attendance, with its consequent poverty and low standard of living, in its frequent shifting from job to job, in its undermining of character and stability, in inducing alcoholism and other vices. The man struggling against a physical defect uses up every ounce of energy and loyalty to support his family. Can he have any loyalty left? Is it human to expect it?

Are we going to meet this great medical and economic question by the general introduction of the physician in industry or are we going to sit idly by and permit the propagandists to persuade our legislators that compulsory sickness insurance alone will assure every worker adequate medical service. I personally disbelieve that compulsory sickness insurance will produce that result, but this legislation is inevitable, unless industry grasps its opportunity and shows society that it is willing to undertake a method of health insurance through its own dispensaries, whose costs will be negligible compared to compulsory sickness insurance and whose results for national health will be infinitely greater. If business isn't big enough to see the social and economic advantage of some system of self-imposed compulsory medical supervision of employees, then some of the most staunch opponents of compulsory sickness insurance will have to become its active proponents.

The industrial dispensary will lessen disease, increase the number of working days as well as working capacity and thereby increase the purchasing power for adequate medical service for the families of the workers. Medical care in industry is not a charity. It pays the best dividends of any department in business. It secures a new arm to the health department and makes possible preventive medicine on a scale yet undreamed of. Witness the reduction of 75 per cent of the lost time on account of illness in the employees of the Norton Company who use the medical department. In attacking directly such problems as personal hygiene, bad housing and living conditions, alcoholism and venereal disease, it will make a real contribution to national health and social welfare. It will immediately help cure the legislative mania with which the American people are cursed.

DISCUSSION

R. G. Williams emphasized Dr. Geier's statements, citing The Norton Grinding Company, which for a number of years had been practising a good many of the things Dr. Geier advocated. This company had an industrial health department, and it was just as indispensable as the telephone. They could prove to anyone interested that it was a dollars and cents proposition. As an example, soon after the department was installed and the men were just getting confidence in the work, an epidemic of grip broke out in the town. About half of the men who developed symptoms immediately got in touch with the plant physician; the other half did not, but held off as long as they could, and eventually lost considerable time. The men that used the hospital lost on an average 19.2 less hours per man per month than the men who did not.

Frank B. Gilbreth said that he wanted to emphasize one statement in this remarkable paper, not with the idea that it was the most important, but that that one thought would warrant the paper even without the rest of its contents. He referred to the conservation of industrial workers.

"We are very much interested in the work of conservation of industrial workers who have been crippled both in the war and in the industries," said Mr. Gilbreth. "It will probably surprise you to know that in Canada the number of cripples who return from the war is not as great as the number of industrial cripples for the same length of time in Canada. Statistics showing this may be obtained from those in charge of the re-education of the soldiers in Canada. Statistics from our own country are published in a remarkable book to be obtained from the Commissioner of Vital Statistics of the State of California.

"In the work that we have been doing with the coöperation of people in foreign countries, we have found a tremendous number of jobs for crippled soldiers as a result of which they can practically date the beginning of their financial prosperity from the time that they were injured. The work undertaken in finding occupation for these industrial cripples has been successful to an extent that has been perfectly astounding, and the same thing will apply to placement of re-educated industrial workers, if they are given proper attention.

"The great need is for adequate teaching, and this need can best be met now, when the subject of the cripple holds worldwide interest. Immediately after the war began I went to Washington to try to get a bureau started somewhere that would take up the question of providing teachers for crippled soldiers, with the idea of training them so that we could properly handle the cripples that will come back to us. It takes two years to teach anyone to handle the best methods of teaching cripples and it is absolutely necessary to make preparations *now*.

"Mistakes have been made in other countries in the matter of teaching crippled soldiers, where they have often been taught to make baskets, because the vocation of basket making might have been the only one that the teacher could teach.

"The cripple must be taught *not* primarily what the untrained teacher wants to teach, but *what he needs to learn.* He must be provided with an occupation that develops him mentally and physically, and that satisfies his desire to do "a man's job."

"It is the duty of this Society to see that the training for efficient teachers is provided not only in the schools and colleges, but also in the industries. The teachers must know how to prepare the cripples to go back into our shops and offices—must be able to furnish practical as well as theoretical knowledge.

"Then, when the need for re-educating war cripples is over, they can turn their energies to the cripples of the industries, to whom Dr. Geier has so eloquently called our attention."

F. A. Geier closed the session with a word of appreciation. He said it was the Local Committee that decided on what the program should be for the session, and he was very happy to feel from the applause that the subjects were well chosen. It was the Committee's purpose to impress upon the members of the two associations at this particular meeting the great value and their very great obligation in the matter of considering the worker in the shop.

They had had papers in both societies on the construction of buildings, on the construction of intricate mechanism, and on increased production. But the main thought among the Cincinnati Section was that they would like to impress those present that there was now the greatest opportunity put before them, namely, the earnest and sincere study and investigation of the human element.

FIRST MUNITIONS SESSION, ALL DAY WEDNESDAY

THE feature of the Spring Meeting which proved of great interest from the professional standpoint was the topical discussion arranged by the Committee on Meetings on the Fundamental Problems Involved in the Manufacture of Munitions. It was planned to have two sessions for this discussion, on Wednesday and Thursday mornings, May 23 and 24. The subject was considered so important, however, and the interest was so sustained that the Wednesday morning session was continued throughout the afternoon of that day, in spite of the fact that a boat ride on the Ohio River had been arranged by the local Committee for Wednesday afternoon.

The attendance at all of the sessions was large, numbering at times as many as 300. President Hollis, who presided at the beginning of each session, called to his assistance as chairmen L. P. Alford of the Committee on Meetings and John H. Barr, Manager, and William B. Jackson, Vice-President, Am.Soc.M.E. Representatives of the Government in attendance were Lieutenant-Commander R. R. Adams and Major P. S. Bond.

The initial discussions, or papers, published in THE JOURNAL for May, touched upon some of the vital problems which manufacturers of munitions have to meet, such as munitions contracts and their financing, organization and procuring of special machines, designing for quantity manufacture, procuring materials, limits and tolerances, gages and small tools and inspection.

There was a strong sentiment at the meeting in favor of some action by the Society of a constructive nature which would be helpful alike to the Government and to those who might be called upon to manufacture munitions.

A deep impression was made by representatives from Canadian manufacturing plants, who emphasized the importance of coöperation among manufacturers, and the pooling of information by manufacturers for the benefit of all concerned,—in other words, coöperative manufacturing as carried on in Canada, as opposed to competitive manufacturing which has prevailed to so large an extent in this country.

Naturally, there was much interest in the relations of the small manufacturer who might be a sub-contractor for the large manufacturer. There was considerable discussion also, as to the possibility of the Society becoming a clearing house for information, even to the extent of undertaking the collection and publication of data upon the manufacture of munitions in the form of a handbook or otherwise.

In order that the discussion might be without restriction and of the utmost benefit to those in attendance, it was agreed that where requested the remarks would not be reported. In several instances this desire was carried out.

At this session the following papers were presented, the first three in the morning, and the last three in the afternoon:

MUNITIONS CONTRACTS AND THEIR FINANCING, Frederick A. Waldron.

ORGANIZING FOR MUNITIONS MANUFACTURE, Arthur L. Humphrey.

ORGANIZATION FOR MUNITIONS MANUFACTURE, Harry L. Coe.

PROCURING SPECIAL MACHINES FOR MUNITIONS MANUFACTURE, H. V. Haight

PRACTICAL WARTIME SHELL MAKING, Lucien I. Yeomans

THE DESIGN OF MUNITIONS FOR QUANTITY MANUFACTURE, J. E. Otterson.

GENERAL DISCUSSION: REMARKS BY LIEUT.-COMMANDER R. R. ADAMS, U. S. N.[1]

Lieut.-Commander R. R. Adams, U. S. N., who attended the meeting as the official representative of the Bureau of Ordnance, said the policy of the Bureau had been to direct its representatives "to coöperate with the various manufacturing firms to which they are accredited in every consistent and proper manner." It had also given directions that the inspector facilitate the manufacture and expedite deliveries wherever possible, provided that satisfactory and acceptable material was procured by the Government. To accomplish this in every instance was impossible, but by the exercise of tact and patience in the case of firms unacquainted with Government methods and requirements, it was believed that many of the difficulties which would ordinarily crop up could be eliminated.

The Bureau desired its representatives to advise the firms in their district as fully as possible, and where possible to make decisions within the scope of their professional knowledge as to the suitability of the materials to be used.

Even with these instructions, cases would arise which had to be referred to the Bureau of Ordnance, but by the use of telegrams and long-distance telephones for important decisions serious delays in manufacture could be eliminated. The Bureau had requested its representatives to make suggestions to the manufacturers, where it was thought that such suggestions would be of assistance, or to give any general information which would help in the manufacture of material required by the Government. Information was volunteered if it would aid manufacturing processes and at the same time did not violate confidential matters disclosed by other firms. But matters of a confidential nature which had been confided to the Inspector were not to be divulged under any conditions.

The Government representative or his inspector was directed to assist in the manufacture of material as far as practicable in addition to inspecting it for acceptance, where such assistance was requested. Our country desired to prevent trouble with regard to new munitions plants such as was experienced in Canada for some months after the outbreak of the war. Many munitions plants in Canada failed to turn out satisfactory products because of lack of coöperation among the plants. This had finally led all plants to pool their experience, and the success of one plant was followed by others until all had the necessary experience. This should be done in this country in the near future, and all information and experience required for the manufacture of munitions should be pooled by the different plants so as to assist other plants, especially the new ones.

Reuben Hill commented on present conditions as they existed in this country with respect to the war, and gave sound advice to those who earnestly desired to serve the Government. He spoke from his experience in munitions manufacture in Canada, and had the closest attention of the audience.

The speaker deplored the apparent apathy in relation to the organization of our industrial forces to support those men that we must necessarily and immediately send forward to the front. He also took the view that the general public were not taking the situation seriously enough and that they would not realize the gravity of the situation until the men that we had sent to the front had been killed. This was based on the fact that the people in Canada were living very close to the war;

[1] Inspector of Ordnance, Munhall, Pa.

[illegible] words, they had been "burying their dead." Therefore they realized how essential it was to back up the men at the front with sufficient material and munitions in order that a great deal more might be accomplished. He also referred to the sad conditions of the past, which was general history now, in relation to the bad start that Great Britain and France made by allowing the best men to push to the front at the beginning, and thereby crippling the maintenance of the industrial support.

He further emphasized the necessity of prompt and immediate attention to the organization of the industrial forces which was necessary now, suggesting that the Government take a more coöperative and guiding activity in relation to the manufacturer, thereby departing from the peace-time methods of arbitrarily giving a contract, and then at a certain time sending some one forward to inspect the work, and either arbitrarily accepting it or rejecting it.

He also advocated that the Society, by reason of its membership in practical engineering, should be of great assistance to the Government in formulating an ideal coöperative industrial scheme, similar to that prevailing in Canada, with the Imperial Munitions Board.

Frank B. Gilbreth emphasized the importance of recording all details, including the time element, with respect to industrial operations, and referred to the use of the micromotion film for this purpose. He said in part:

"We hear much of the loss of information to the world when the great library at Alexandria was destroyed, but we hear little or nothing about the wonderful amount of information in the heads of our workingmen, who have not been properly trained to pass on that information in literary form so that the public can get the benefit of it.

"The best method of doing any kind of work does not lie in the consecutive acts of any one worker, but is synthesized from records of methods of many expert workers. When these skilled but uneducated experts referred to die off without passing on their information in any way, the best elements of the methods that should be recorded and passed on are lost to us forever.

"There has been some confusion between the ordinary motion picture film and the film used in making micromotion study. The micromotion film is the result of placing a timepiece that records the *time* element, and a cross-sectioned screen that records the *space* element in the field of the method to be photographed. The pictures are taken at varying rates of speed, and are then projected at the speed at which they are taken, at slower speeds and at more rapid speeds, in order to get different views of the operation being studied. The pictures are studied one at a time, the film being run forward and backward, and a cycle of motion being reviewed as many times as is desired. The two aims are, first to get all possible detailed information on the film, and second to get this information off the film and into the simultaneous motion-cycle charts, or such other form as will aid in transferring the information most easily and most efficiently to the learner. The stop watch can make no such adequate records as this. I would urge that all observations should be made once for all by the most scientific methods possible."

Harry E. Harris told something of the industrial mobilization carried out in Fairfield County, Conn., the county in which Bridgeport is located and which has been called the "Essen of America." He said in part:

"On April 4 the manufacturers in the county held a meeting with the members of the chambers of commerce, boards of trade, philanthropic societies, granges, and the Farm Bureau and organized a patriotic association which expects to raise in the neighborhood of one hundred thousand dollars from the people of the county and to have a membership which will embrace every man, woman and child.

"The object of this association is coöperation and there are six chief departments: Manufacturing, Transportation, Industrial, Relief, Welfare and Agricultural. The Industrial Department, which we are interested in as engineers, has ten divisions of work, one of which is the establishment of an interchange of measurements. The different manufacturers who have facilities for measuring have offered them to the association and experts in measuring who reside in the county have offered their services. Committees have been appointed which are already working in conjunction with Dr. Louis Fischer of the Bureau of Standards. The Association has offered its assistance to the Bureau of Standards and to the different manufacturers with a view to securing accurate local standards and means of measurement. It will be the aim to work in conjunction with the different Government inspectors.

"There is a committee for securing the coöperation of labor, one on industrial efficiency, and one on the training of employees."

Lieutenant-Commander Adams in response to an inquiry as to what could be done to facilitate delivery of material, said that the steel-manufacturing firms in this country had authorized the Government to call on them for certain amounts of steel at a fixed price: but at the present moment most of those firms have been filled up with Government material. He said that there were a number of steel firms throughout the country that were not doing their part. That question was being considered in Washington, and would probably be taken up in the near future. If any firm in his district had difficulty in getting steel, he took it up direct with the steel corporation in the district and had so far succeeded in getting steel within 90 days, sometimes in two weeks. The question was being considered at Washington of giving more power to some Government official who would have power to assign certain deliveries of steel to certain plants at a fixed price.

President Hollis urged that some constructive action be taken by the meeting as the most obvious thing to do, inasmuch as the men in attendance represented the productive industries of the country. He suggested that a committee be appointed to draw up resolutions for consideration at the next session, offering helpful suggestions to the Government and possibly suggesting the establishment of an effective central bureau on the whole subject of gages. He believed it was most important that some such action be taken by the Society to help accomplish the thing that Canada and England have required a long time to bring about, so that there would be fewer mistakes to start with.

W. H. Carrier expressed his approval of the suggestion by President Hollis and said that he himself was about to suggest a coöperative board to determine what mechanical manufacturing problems could best be handled by the engineers and manufacturers of the Society. Such a board should take a census of the membership to determine what the individual members were capable of doing, to find out which of them were specialists in different lines that would be useful to the Government—in short, what the problems were and who were the men to solve them.

As a result of a motion by Harry L. Coe, it was voted to ask that a committee be appointed to draw up resolutions.

DISCUSSION ON MR. WALDRON'S PAPER ON FINANCING

In presenting his paper Mr. Waldron spoke of the financial protection required by a manufacturer in taking a contract from a foreign government. If it were simply a business firm with no tangible assets in this country, the usual practice would be to have an advance payment to cover the expense of preparation and to insure against financial loss. In turn, the government advancing the money must have suitable security, which might be in the form of a bond. In many cases the hugeness of the contracts had not been fully appreciated and they had been undertaken with a smaller advance than would have been demanded under similar conditions in the conduct of the regular business of the firm. In particular was one contract of \$84,000,000 taken with an advance of \$10,000,000, which, while it seemed like a large amount, was only 12½ per cent of the total. Later the advance had been increased to \$12,000,000.

R. Poliakoff[1] said that Mr. Waldron had mentioned the fact during the presentation of his paper on financing of munitions contracts that a concern had taken a contract for \$84,000,000 with an advance payment of only 12½ per cent of the total value. He did not know what concern Mr. Waldron had in mind; but he knew of a similar case of a contract of \$84,000,000 and with the same advance payment of 12½ per cent, or \$10,000,000.

It was assumed that a contractor who entered into a munitions contract took also upon himself a certain moral obligation, because the equipment of the army depended every day on that contract, and any delay in the execution of the contract became a serious matter. Could a foreign government be blamed, then, when it gave a contract of \$84,000,000 and did not advance to the contractor, say, \$30,000,000 for which he might ask, especially if the contractor before the war had been rated as a concern with a capital of from one to three million dollars?

Of course, a guarantee for that advance payment could be secured, but how? Well, by surety bonds. But according to the last information of the Treasury, up to August 15, 1916, there were in this country only twenty-six surety companies, with a stock capital of about \$27,000,000 and a surplus capital of \$20,000,000, making a total of about \$47,000,000; moreover, according to the law of this country, none of these companies was allowed to issue surety bonds pertaining to one contract to the aggregate amount of more than ten per cent of its capital and surplus. This meant that even if all the surety companies in the country should pool surety bonds to the largest amount possible, in order to protect one contract, the sum would not exceed \$5,000,000. He certainly hoped that in the new contracts some other method of financing and some other method of advance payment would be devised. For it was no easy task to get back money from a contractor who did not live up to his contract.

Again, Mr. Waldron had stated that some contractors had been trying to get contracts even with very small advances, and that these small advance payments must be considered perhaps as one of the reasons why the contractors could not go on. But this was because the contractor could not ask for financial assistance from his bank unless he had the contract in hand. The bank would not give him money unless he had a contract which could be used as a guarantee to protect the bank. Thus the contractor would try to get a contract even with a small advance payment. Therefore small advance payments were by no means the reason of failure of some of the contractors, and the true cause of such failures had to be attributed to different reasons.

Professor Poliakoff, speaking at a later session on Mr. Walsh's paper on The Inspection of Munitions, referred to the points he had made in his discussion of Mr. Waldron's paper for the reason that both writers spoke of the same contract. The Professor said he was authorized by the Russian Government to state that a printed statement concerning Mr. Walsh's remarks was in preparation, which, with the consent of the Publication Committee, would be contributed later to THE JOURNAL.

DISCUSSION ON ORGANIZATION, BEARING PARTICULARLY ON THE PAPERS BY MESSRS. COE AND YEOMANS

James Hartness spoke in commendation of all the papers, and particularly of Mr. Coe's contribution on the subject of Organization. He spoke from personal knowledge of the energy, persistence and practicability which Mr. Coe had displayed in reorganizing work for the company with which he was connected, and said that the principles outlined in the paper were worthy of the widest publicity at this time.

H. B. Coho[2] (written), who was in charge of the business organization of the United States Cartridge Company's plant at Lowell, Mass., explained the system of coöperation which they had instituted. Their working force had been increased from 300 to 8400 in considerably less than a year, and their output from 100,000 a day to 2,000,000. They were fortunate in procuring the coöperation of the machine builders, and in having a man in their mechanical department who was not only familiar with cartridge manufacture, but also had a big enough vision to see what would be required so that orders for supplies could be placed ahead.

The company was favored by having available for its work an intelligent class of operatives, who realized that success or failure rested almost solely upon them. In appreciation of their special efforts the company introduced many factory betterments, such as free medical attendance and examination, restaurant facilities, rest rooms for the women workers, first-aid and safety-first. Great attention was paid to a welfare committee, which was organized from among the workers themselves. The labor department, through which all of the 7700 odd people were procured, took the trouble to show the prospective employees the advantages they would derive in this plant over those to be derived from manufacturing plants in other locations.

The services were secured of a great many young men who had been educated as efficiency engineers at the Massachusetts Institute of Technology. The firm had found the difficulty with efficiency men to be that they had cure-alls for everything which they discovered to be wrong, but comparatively little original experience on which to base their experiments. They were, therefore, told that it was not a case of providing medicine for a sick institution, but rather an opportunity to take one department and organize it so it would be synchronous with all the other departments and form a useful cog in the wheel. Results spoke for themselves, as it was now one of the best organized small-arms-manufacturing plants in the United States.

One thing that contributed to the success of the organization was a system of conferences of the various shop committees.

[2] United Lead Company, 111 Broadway, N. Y.

The meetings were conducted along parliamentary lines and a competent stenographer was always present.

A. B. Reynders[1] sent a communication endorsing the statements in Mr. Coe's paper and outlining briefly a method used by his company in the manufacture of high-explosive shells, which secured a large and continuous production after the equipment and operating force had been organized. The method embodied the following features:

1 Piece-work system of wage payment to machine-tool operations. This contained a differential factor; that is, the price per piece increased with an increased output.

2 A liberal bonus system to the supervisory force based upon the following:

a Quantity output

b Expense

c Man efficiency, that is, the ratio of the workmen's earnings to their day rate.

3 A load or bogey set at the beginning of each month for

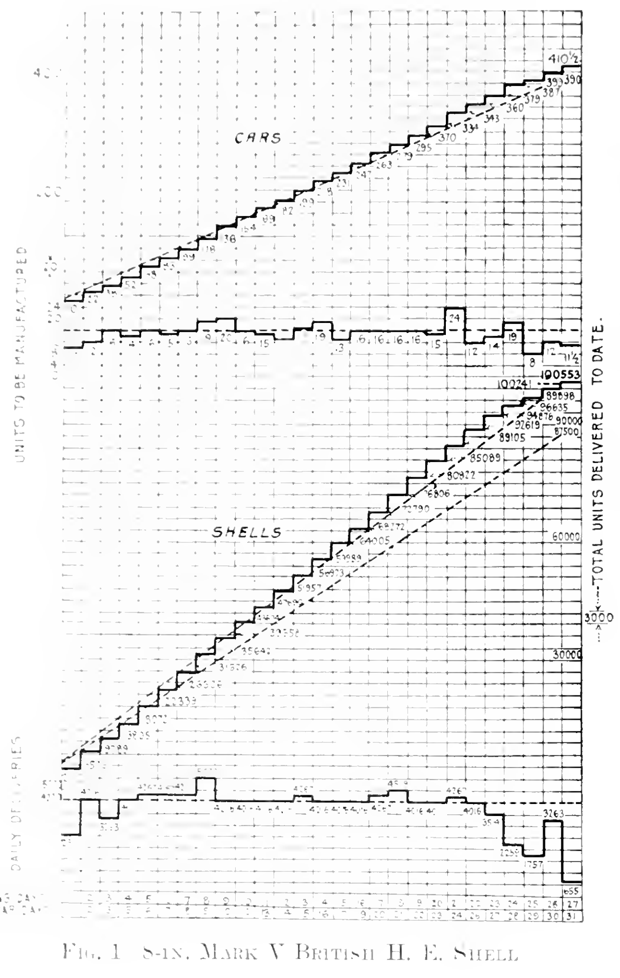

FIG. 1 8-IN. MARK V BRITISH H. E. SHELL

the desired output for that month. This bogey was shown as a diagonal line, as drawn on the accompanying chart, Fig. 1. Each day's output was charted in a step curve.

If the corner of the step touched the diagonal line, production was up to requirements. These charts were fastened to boards and distributed throughout the factory where they could be seen by all of the supervisory force. When the output was satisfactory, the common expression was that they were "hitting the line."

[1] Director of Production, Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa.

4 In addition to the visible charts for keeping a record of production, a tabular record by operations was maintained. This was reviewed each morning by the manager or superintendent. Any abnormally low output of any operations was immediately checked to see if it was temporary, and if permanent, corrective measures were applied. It was found that this check has to be kept up continuously, as a failure to do so usually settled into a chronic lack of results.

5 An adequate supply of material had to be maintained for continuous production. This meant a large storage space, careful checking with the suppliers of materials, transportation companies, and frequently manufacturing the material by the company itself.

H. G. Bertram wrote giving an account of the organization of the plant with which he is connected (the John Bertram & Sons Company, Ltd., Dundas, Ont.) for the manufacture of 8-in. British howitzer shells. Their regular line of work is machine tools, but the organization for the manufacture of shells is entirely separate.

Upon receipt of their order, the major operations were outlined and the production expected per machine at each stage. Orders were then placed for the necessary machinery and the dimensions of machines secured to which it was expected to fit attachments. As the lathes were purchased without special equipment, great perseverance and close application to the smallest details were required so that the lathes would be ready to run when put under the belt.

Their working gages were made in their own shop from blueprints supplied by the Imperial Munitions Board. When these were ready and the equipment was fitted to one machine in each operation, a shell was carried through at once to see that everything was satisfactory and the finished shell produced was up to standard. Minor changes were made, and half a dozen forgings carried along to see that no failure was likely to crop out. During this time other machines were being installed, and by the time the fixtures had proved satisfactory a start was made on a larger scale.

Following then Mr. Coe's paper, the organization, wrote Mr. Bertram, is made up as follows:

1 GENERAL SERVICE DEPARTMENT:

a Records and Accounting. This is a bookkeeper's work. The shop is charged with components received and credited when shipments are made. In addition, a record is kept of the disposition of all the shells in each heat. The necessary records are sent in from the various departments, such as receiving, shipping, inspecting, etc. The value of these records should not be underestimated, and all information regarding the shells should be carefully filed.

b Purchasing and Stores. The former is handled by the regular shop staff, while the latter is under a special clerk, who checks all shipments coming in and going out and sends a report to the Accounting Department.

c Designing and Drafting is still looked after by the department that got out the tools and fixtures, but with a much reduced staff.

2 DIPLOMATIC STAFF:

This is a very necessary department and is handled in our works by the sales engineer. Quite often the members of the production or engineering staffs are so worried by a breakdown or other troubles that they have not the time to give visiting officials or manufacturers the proper attention. Our sales engineer actively coöperates with the Engineering Department in outlining the machining operations and equipment, and is in a position to give all the necessary explana-

tions. In this way visitors are entertained without interfering with production.

3 PRODUCTION DEPARTMENT:

a Maintenance of Equipment. Orders for repairs are handled by the original Engineering Department, as they are directly in touch with the various designs, and know whether or not a broken part should be strengthened. They also have the necessary tracings or drawings.

b Operation of Equipment and Training of Workmen. The operations were subdivided into seven small sections (this has later been reduced to six), and placed at the head of each section is a mechanic drawn from the regular shop force. These men are paid a good salary and bonus on shipments, and it is their duty to teach the new operators, many of whom never ran a machine before, to keep the heats running through in order, to watch their machines for failures and check them frequently with indicators to insure perfect work. They are also encouraged to keep a notebook and jot down anything unusual about any of the work going through their department.

c Establishment and Operation of Wage Payments and Penalties Systems. The piece-work system is introduced as soon as records could be figured on. The prices set are fixed for the first order only. Each man is handed a slip daily showing what he earns, so that all errors can be immediately corrected.

Penalties are established, and, while the price is a small part of the cost, it tends to make the workmen more careful.

4 INSPECTION DEPARTMENT:

The Chief Inspector is chief inspector in the machine-tool department. He looks after the Operation Inspectors, checks all gages frequently, sees that the sub-foremen correct promptly any errors in workmanship which might develop, and, being a first-class mechanic, he keeps generally in touch with all branches of the work.

Operation Inspectors receive the shell after each operation, and, after gaging, stamp their mark after the operator's letter or number. Their report at the end of a run is used to check the operator's production cards. They are instructed to insist upon "quality" before "quantity."

On the 8-in. shell the rough turners have no limit allowed—the inside boring bars are set in the tool room and are between the mean and the high—while no limit is allowed for finish turning. In this way all the shells are cut to the same length over all, instead of weighing each and then cutting to suit.

In many other cases the limits allowed the workmen are reduced.

An inspector goes over the shells before the Government preliminary inspection, and also before the final Government inspection. The final shop inspector has the only shop scales used on the 8-in. shells, and it is a rare thing to find a shell over or under weight.

A special inspector, called the Steel Inspector, watches the forgings, especially after rough turning, for seams or cracks. In this way defective forgings are cut out immediately. The Steel Inspector sends a "defective" record to the shop stores clerk, who checks the shells into the yard and sends the records on to the Accounting Department, where the number of defectives is charged against the various heats appearing on the record.

Discussing Mr. Yeoman's paper, Mr. Bertram said that the greatest difficulties to be encountered by the prospective shell manufacturer were lack of appreciation of the magnitude of the work and lack of organization. The average manufacturer could not hope to equip and bring a large plant up to capacity in less than five or six months. In his own plant, after having practice on two smaller sizes of shells, they prepared machines, tools and gages for 8-in. shells, and thought they did very well to make shipments in about four months after receipt of order. Continuing, he said:

"The statement that an entire plant can be erected, fitted up and operated to capacity in sixty days is most unusual, and would call for explicit information regarding deliveries of material which, unfortunately, is lacking. The feat might be accomplished if one were able to command all avenues of supplies; but being dependent, as one is, upon so many different concerns, each one of which is being held up in turn for want of raw material, strikes and other troubles, one might well cry that it is impossible.

"However, the present war should not require the establishment of such mushroom factories as outlined by the author. There are already many shops fitted for the manufacture of shells, and thousands of others with their organizations, money and machinery, ready to place all at the disposal of the Government; and I truly believe that these shops, with their loyal following, will be able to handle the munition work more economically than shops held together by mercenary officials.

"The type of plant suggested is open to criticism. It presupposes the use of machine tools with a single-pulley drive, with the pulley conveniently located for belting horizontally. This brings up the question whether it is easier to erect a building suitable for all machinery or build machinery suitable for all buildings, or none at all. In starting up a shell plant, engineers without previous experience at their command on the particular size of shell under consideration often prefer cone-driven machinery, owing to the greater range of speeds and feeds obtainable (especially by the use of a two-speed countershaft)." As to leaving the machines exposed, Mr. Bertram said "this would be quite satisfactory in summer if it were not too hot or did not rain, but I suppose sunshades could be supplied at a reasonable cost and operators could be requested to bring their own umbrellas."

Ralph E. Flanders offered some information with reference to 15- and 18-lb. shells, which he believed to be authentic. He said: "We have more than enough shop capacity for their manufacture: at least for our own use. The capacity that has been developed for the English and Russian contracts far surpasses the largest possible consumption that our 15- and 18-lb. guns can take care of. For this reason our attention will probably be directed toward the increase of the gun output on the one hand, and, on the other, toward making larger sizes of shells from 4 in. in diameter up."

In reference to the point mentioned by Mr. Bertram in the discussion of Mr. Yeomans's paper that the most valuable single asset of any firm starting or contemplating the manufacture of anything was its organization, Mr. Flanders said this should be strongly emphasized as a general principle. "This does not mean the paper organization or certain forms and methods of doing business, but the vital organization of a group of men who are used to working together, who know each other, and have a fair degree of knowledge about their jobs. They do not all have to be wonders. They do not all have to be 'top-notchers.' But if they are ordinarily earnest, intelligent men, who have been working together for a number of years, and know each other, they will eventually accomplish more than can be effected by an organization of the greatest group of experts in the country who have never seen each other before."

He was sure that in contemplating work for the Government in this crisis, we must all count on our organizations as being

[illegible] things we could offer to the Government. We would [illegible] from patriotic grounds of anything that would tend to [illegible] up these organizations in their vital [illegible].

DISCUSSION ON COÖPERATION AMONG MANUFACTURERS AND THE POOLING OF INFORMATION

The reference by Lieut.-Commander Adams, in his remarks before the meeting, to the coöperation which now existed among Canadian munitions plants, and to their practice of pooling information, led to a general discussion of this subject.

Secretary Rice believed that the point brought out by Lieutenant-Commander Adams in respect to the free interchange of data among Canadian manufacturers was the most important that had developed during the convention. In Canada every citizen not only had a right to go into the plant of every manufacturer of munitions to witness the processes of manufacture, but was cordially invited to do so and if he could improve upon the processes, he was privileged to proceed with the manufacture of munitions on his own account, through the information which he has secured, for the common good of the Dominion.

As President Hollis had emphasized in every way possible, and in doing so he has been an inspiration to the Society and to the profession, the supreme effort at this juncture should be for the engineering profession as citizens of the United States to work for the common good of mankind.

William Kent asked if the Government had a bureau to which a manufacturer could apply for information as to the best way of doing a particular machine operation. The case in point was that of a manufacturer doing Government work, who had been experimenting to find out the best way of accomplishing it, but who did not know if the same work had been done before, or if done, by whom it was done.

Lieut.-Commander Adams replied that the proper way to handle such a question would be to take it up with the officer inspecting the material, who would write to the Bureau for the information. If available, the Bureau would inform the company through the inspector where the work was being done, and whether the process could be seen or whether simply a written description of the method would be all that could be sent to the Government.

Reuben Hill, in further answer to Mr. Kent's inquiry, explained the way in which such matters are handled in Canada. He said:

"The Imperial Munitions Board of Canada is organized to create a spirit of 'help one another' among the munitions manufacturers of Canada. Very frequently we have received letters from the office of the Imperial Munitions Board asking us to permit other manufacturers to visit our works and investigate our methods of manufacture. This has been freely permitted, since the Board has explained that the output of a certain number of firms would in any case be required in order to secure the necessary production, and that information given out would in no way affect the amount of work which firms would do individually.

"Prices which the Government pays are known to each of the manufacturers, which still further removes any doubt as to competition. For instance, we have devised a certain tool which has been very useful in obtaining great precision in time-fuse making. Concerns hearing of this, write us asking whether we will send them blueprints of such tool. We make no fuss over it, but immediately mail them the blueprints, at the same time asking them if they require any further information.

"A few weeks ago I had a little doubt as to one of the processes in the manufacture of time fuses. A concern in Toronto very willingly permitted me to send a representative to its plant to inspect the manner in which it performed this particular operation. Shortly afterwards we received a letter from this concern stating that it appreciated the visit of our man and that it would be pleased to do anything for us, and invited us to pay an additional visit. This is the correct spirit to maintain among manufacturers, and, as I stated, this Society should be the main factor in inculcating this spirit in the United States.

"I distinctly remember that at the commencement of our fuse making I paid visits to several concerns. One of the things I was most interested in was the correct formula for the mixing of brass, in order to obtain the necessary tensile strength. It was impossible for me to get any manufacturer to explain his formula, as he considered it a shop secret. Today there are no secrets at all in relation to this, inasmuch as everybody in Canada knows the exact formula and the way to work the metal. Unquestionably, should this Society start a coöperative spirit of this kind with the Government it would prevent many delays, and, individually, I would willingly undertake to assist the Society in any way with regard to types of machines or designs of tools that would aid in the manufacture of fuses."

Frank O. Wells was in sympathy with the idea of this organization helping the Government and of getting together to supply it with proper information. As he understood it, before war was declared no Government official could add to his force in any way, but the minute war was declared they could not find room enough for the officers in Washington. Thus the Government should have all the help possible from this organization and others similar to it.

Mr. Wells was informed recently by a naval officer in Washington that they had four times the capacity necessary to make shells up to and including 6 in.—four times the capacity of their needs. Whether that was correct or not he did not know, but the officer was in a position to know. Regarding the pooling of information, he was sure that many did not know that the Government had had officers in the different factories gathering data for the use of manufacturers.

Mr. Wells believed that all should coöperate, and that he himself would be only too glad to welcome everybody to his factories; in fact, cards had been issued asking all to come. Instead of each manufacturer experimenting individually, why should not the Government organize a clearing house to serve all manufacturers?

Chester B. Hamilton, Jr., contributed from his experience with the system of coöperation in vogue in Canada. He said in part:

"We were lucky in not having started on the competition basis at all. The shops began by sharing ideas when the orders first began to come through. I think there is not a single shop which refuses information that would tend to increase the capacity of the whole. Any of you who will come to any of our shops in the Dominion will get a thorough welcome.

"I do not know how it is proposed to handle the general contractor question in this country. The larger shops experience many difficulties in doing the work required on fuses, cartridge cases, primers, and the various components of the shells themselves. It is a man's job to look after a shop doing

any one of those things; and the shop where the boss knows the individual will get out delivery ten times faster than a large corporation. In Canada, the Imperial Munitions Board is the general contractor, and buys all the material and turns it over to the component contractors. They make their components and account for the material under inspectors employed by the Imperial Munitions Board. The component parts go, according to the directions of the Imperial Munitions Board, to the various machining and assembling plants, where they are to be worked upon and again inspected and counted, and then shipped on to the loading station, where the fuses and explosives are added. At the loading stations they also receive cartridge cases, primers and propelling charge, and there the completed round is turned out. In short, it amounts to a system of subcontractors, with the Imperial Munitions Board as a general contractor. The plan works out well, because nobody tries to do up somebody else or steal his profit. We are all knit together; it is all in the family.

"As for gages, there are not tool makers enough to make them. We have a few, and the rest are good machinists that are willing to take instructions and be as accurate as the requirements call for. It is the same way in the production department on the munitions themselves. We are running with about two mechanics to a gang, a foreman and a deputy foreman, or instructor; the rest are anything or anybody that we pick up. A good many of them are returned soldiers, wounded men who have recovered from their wounds but are not fit for further service at the front. We see the boys that we worked with last year coming back in pieces. Some of them are able to work at a new trade. We are trying to work them in as well as we can for single operations or repetitional work. Men that are maimed in one member or another can usually be fitted into something within their capacity.

"The first question that Mr. Waldron brought up with regard to the advance payment is not as severe under our method of organization where the Government owns all of the material. We touched the low-water mark, financially, at about sixteen per cent of the value on our first contracts. Size of contracts is unimportant. I do not know how many contracts we have had. It is a continuous system flowing straight through. Anybody figuring otherwise is working on a wrong supposition.

"There is a whole lot more I would like to tell you, but I do not want to go on too long. But wake up, wake up! You are up against a far bigger thing than you have any idea of now: Get the coöperation idea into your head, the idea of working together, not as units or individuals, but all working together."

Ralph E. Carpenter said he personally knew that the Army was working in conjunction with the Bureau of Standards to establish just such a Central Inspection Bureau as had been suggested; and also that the Bureau of Standards was waiting for legislation that would give it increased appropriations. Now it was absolutely tied hand and foot for funds. If this Society should draft a resolution to the proper authorities at Washington that would lead to the appropriation of funds, something would be accomplished which would be modeled after the scheme used in Canada. There would be a bureau for the inspection of gages and the establishment of standards which would assist everybody engaged in the manufacture of munitions.

Mr. Carpenter voiced the sentiment of the manufacturers of this country by saying that they were all willing to coöperate to the fullest extent with every facility that they had at their command, but that the extent to which they would coöperate depended upon the attitude of the Government. At the present time the attitude appeared to be one of competitive bids, which naturally produced competition, but eventually he believed the authorities at Washington who were interested in the manufacture of munitions would work out a comprehensive scheme which would largely eliminate competition.

During the past year the various engineering societies had made every effort to canvass the whole country as to the facilities that were available in the various plants. At the Frankford Arsenal, Mr. Carpenter gathered the impression that they already had a tabulation of all the available facilities and what they could be used for. They were also disposing of some big contracts for the smaller sizes of artillery ammunition. These contracts were being placed with manufacturers who had facilities for doing that work, and eventually they would require the aid of almost every shop in the country.

DISCUSSION ON THE OPPORTUNITIES AND DIFFICULTIES OF THE SMALL MANUFACTURER

E. F. Du Brul said that he had considered the discussion from the point of view of the small manufacturer. In reading different articles dealing with the munitions supply in Europe, he had gathered the idea that practically every machine shop in Germany, Canada, England and France, no matter what its size, had been engaged in making munitions or some war supplies for their respective governments. He had read that many establishments that previously had had no metal-working departments had lathes fitted up in some corner and were turning out shells.

Mr. Du Brul further continued, "It seems from what our Canadian friends said this morning that the smaller shops can produce munitions more quickly than a big organization. In the papers we have had from American manufacturers the contrary seems to be true. The small shop is warned to keep off; but that does not seem to tally at all with the experience in Canada. There the small shops have been turning out large quantities of munitions through coöperation with their manufacturers' association and their shell committees. I think that we ought generally to recognize that in order to help our Government the most, we have first to functionize any activity of this Society along these lines.

"The smaller establishments together employ a great number of machinists and mechanical labor. I remember well that fifteen years ago, when I was criss-crossing the country as Commissioner of the National Metal Trades Association, the man who was quickest to get things done was the man who owned his own business, knew his own business and ran his own business. We always had more trouble with the big organization whose boss was a board of directors than we had in dealing with men who themselves could take prompt action when necessary.

"I take it from talking with others that we smaller manufacturers all want to do our bit, but we cannot find out either what to do or how to do it. It seems to me that we must have talent enough in this Society to work out schemes that would organize these small plants and get their coöperation for national defense. We will never get such schemes from our Government. We must do for ourselves some of the things that the Canadians and British have done.

"Those who heard Mr. Hard talk before the Machine Tool Builders will realize that the British had a tremendous task only to get ready; that they had to eliminate civilian control of purely military matters and eliminate military control of matters of production. The same thing will have to be done here. It is aggravating to think of our Congress wasting time

in providing the lump-sum appropriations which it is the business of Congress to supply. Yet a senator, mechanically ignorant, strikes out an appropriation for gages with the remark that 'gages have nothing to do with the production of munitions.' We, above all others, should do everything possible to eliminate lost motion, waste of time, waste of money and waste of American lives consequent on such stupidity in high places."

Reuben Hill, referring to the previous discussion of the situation of the small manufacturer, said: "I will refer again to the Imperial Munitions Board, which takes a keen interest in the manufacturer, and his progress, and, if necessary, obtains for him any materials or parts, etc., which he is unable to secure promptly. The Board brought over from Great Britain expert ballastic engineers, who are available at any time the manufacturer does not understand certain things in relation to requirements. Should the manufacturer, for instance, in making fuses make a certain hole half a thousandth too large, these engineers are called upon to give their decision as to whether such work is acceptable. Oftentimes, if this deviation does not concern a vital functioning of the fuse, such work may be acceptable, thereby saving the manufacturer considerable expense. Should the manufacturer be temporarily delinquent in deliveries, due to conditions beyond his control, efforts should be made to advance certain payments on his contract, therefore preventing a 'tie-up.' This in turn produces a greater coöperative feeling between the manufacturer and the Government, and at times when the manufacturer would have been forced to quit, he gets sufficient confidence from the relationship between himself and the Government to allow him to overcome what might have been an insurmountable obstacle from his viewpoint.

"Realizing that this spirit of 'give and take' or practical coöperation should exist, it is high time that such methods should be instituted, and, acknowledging that this war is a serious proposition, it is time that all practical information such as described previously should be collated for the benefit of the manufacturer. Broad-minded action, as described above, will oftentimes prevent imperfect work surreptitiously passed through, unknown to the manufacturer, by his own men when percentage inspection is resorted to.

"Any further details in relation to this coöperative action on the part of the British Government I will be glad to furnish if necessary."

M. W. Sherwood, who had been shop manager for a subcontractor of one of the larger concerns making 18-lb. shrapnel, said that the shop had only 250 men, who simply finished the forgings that later were processed by the larger concern. Coöperation between the larger and smaller plants was very satisfactory, although the compensation was not entirely satisfactory. Owing to the poor conditions of business existing at the time, he felt that if some arrangement could be made whereby a standard price could be established and paid; or if the work was taken at a price which subsequent developments proved was lower than the average price paid, if an adjustment could be made to conform to this average, he felt that the small shop would be safe in taking contracts from the large concern, or such portions of the work as they were equipped to do.

F. O. Wells felt sure that the Frankford Arsenal would be glad to give the smaller shops information as to the time required to do the work. He had been there several times and had been very courteously treated.

DISCUSSION OF STANDARDIZATION OF GAGES

Lieutenant Commander Adams replied to an inquiry as to what provision was being made by the Government for the inspection of different parts required in the manufacture of shells, so that all these would conform to given standards. The Bureau of Ordnance would issue an order on the Naval Gun Factory to manufacture master gages, maximum and minimum go and no-go gages for the shells under manufacture. These master gages would be in charge of the inspector and would be sent to the sub-inspector at the works and be there used by the company having the contract as a model for their gages to be used in the inspection of this material. He said that the Naval Gun Factory had master gages showing the required tolerances, and these gages were furnished to any company manufacturing shells for the Bureau. The company would make their gages from the Government gages, and would have access to the master gages in order to check up their own gages.

Reuben Hill through an endeavor should be made to adopt a scheme similar to that used by the Imperial Munitions Board of Canada, which involves a central gage-checking department. This department should undertake the checking of all new gages which were supplied to their inspectors at the various plants. After checking these gages they were recorded in the Government checking department's office with a serial number and issued to their individual inspectors. They were then checked by a traveling gage inspector, who, in turn, was followed by a checker who checked the references and tested the pieces used by the gage checker. This department should also be able to check any working gages of the manufacturers should they tend to create a dispute as to the accuracy between the manufacturer and the inspector.

Chauncey H. Crawford said the idea of a handbook appealed to him strongly. It should include a list of the necessary tools with description, and information as to where they could be procured, their cost, etc. Similar information should be given upon gages required in munitions manufacture.

Mr. Crawford, who is engaged in railroad work, said that his road had thought of taking up the manufacture of munitions, but after investigation found that their shops did not have a single tool that was fit for making shells of any size. He felt that the question of making guns was a still bigger one and that they were even further away from being equipped for the manufacture of guns than they were for the manufacture of shells. He believed that a committee of the Society should arrange a clearing house of some kind, with an officer in charge, and raise money to pay him. He would personally see that the railroad with which he was connected would join in the undertaking, and would urge other railroads to do the same. To obtain an idea of the strong organization which America now has to contend with, he recommended that engineers read Roberts' Monarchial Socialism in Germany.

H. Wade Hibbard said the question had been raised among the professors of engineering in attendance at the meeting as to whether it would be desirable for the Bureau of Standards to establish subsidiary testing stations at the various engineering schools throughout the country, so that the manufacturer who wanted to have his gages tested would not have to send them such great distances. The professors of the universities, while not expert in testing gages, were expert manipulators, so that they could very easily acquire the touch necessary for the inspection of gages. A large gage manufacturer had told him that he would be glad to have several professors detailed

at his plant to be put under the instruction of a professional gage-tester for the purpose of entering into gage testing.

Reuben Hill, in answer to the above suggestion with respect to the establishment of testing stations for gages, believed that a scheme would be necessary similar to that of the Imperial Munitions Board in Canada. He said it would be readily understood that considerable delay would ensue if the Government inspectors' gages had to be sent to a central point to be checked. If the manufacturer should be remote from the central gage station, it was obvious that the delay would be considerable. Furthermore, the Government inspector, not being in a position to check his test pieces, would not know if his gages were wearing. This referred, of course, to these gages which were being used by the inspector and not to new gages. The latter should be sent to the central checking station for initial inspection and registration under serial numbers for future reference.

COLLECTION OF DATA PROPOSED FOR BENEFIT OF MANUFACTURERS OF MUNITIONS

Ralph E. Flanders referred to the discussion at the Machine Shop Session held in the morning, looking toward a collection of data on the manufacture of field artillery. That was regarded as an open question of great importance, and it was suggested that papers be secured at the earliest possible moment for publication in The Journal.

H. S. Bergen, speaking along the same line, suggested the idea of a handbook which should contain a classified list of munitions and of the various methods adopted by different factories making such munitions. If this information were available in convenient form, it would greatly remove the necessity for visiting factories, in cases where there might be objections raised to visitors coming in from another plant.

F. A. Waldron felt that, if possible, we should get the wheels in motion whereby information which manufacturers seem to demand could be tabulated either in handbook form or in a card index. He thought there might be a clearing house of the college students willing to go into munitions work; of people who are making special types of gages; those who had been manufacturing artillery—or 3-in. shells and down, or 3-in. shells and up. Such information also would be available for the Government.

L. P. Alford said that the work of gathering information on the manufacture of munitions had been done by the technical journals of the country up to the present time. He considered the complete accumulation of data by this means to be beyond the bounds of possibility, but that it might be feasible to organize a bureau with a sufficient staff to accumulate information so that it might be printed in a rather rapid fashion, because a great deal of the information is already in documentary form in the shops which are producing munitions. He believed that the only way to secure the information would be by having a sufficient number of men to canvass the field personally.

H. S. Bergen spoke of the excellent material on the subject of munitions which had appeared in the *American Machinist*, *Machinery*, and the *Iron Age* and other technical journals. He believed it could be more quickly procured through means of these journals than in any other way. He thought that some working arrangement might be had between the different publications and the Government, not in a competitive way, but with each journal working in its own field.

F. E. Rogers suggested that it might be well to get some idea as to what such a work as had been proposed would cost. He, himself, thought that $25,000 would not be sufficient.

Lieutenant-Commander Adams explained the present method of handling the question under debate. While not as satisfactory as the method proposed, manufacturers on several occasions had written to the Inspectors of the Navy in their district requesting additional information, so that they could turn out the material desired; and if the Inspector lacked this information he would request it from the Bureau of Ordnance, and the Bureau of Ordnance would request it from some other district. The information could not always be furnished; sometimes it was not on hand; sometimes it was confidential; but if the inspector of the district did not have it, he would write to the office and they would write direct to some other manufacturer, and thus, under the Government authority, the first manufacturer could quite often get the desired information much more quickly than it could be obtained by waiting for a handbook to come out. There are inspectors at Midvale, Baltimore, Pittsburgh, Bethlehem, Brooklyn, and in Connecticut. The Pittsburgh district covers Buffalo, Cleveland, Toledo, Detroit, Cincinnati and Louisville, and as far west as Alton, Ill. While the Western districts are rather extensive, they have not got the intensive manufacture of munitions in these districts that they have in the East.

In response to the inquiry by John H. Barr as to whether information which the Government had would be given out to the editors of the handbook, in the event of such being prepared, Lieutenant-Commander Adams said that he usually was permitted to give out information. Ordinarily he would have to write to some manufacturer of munitions, or some inspector or bureau for the information, but the Department, at least, would know where to find it and could direct the editor to the proper authority.

F. A. Waldron called attention to the specifications which are sent out by the War Department, to be attached to the pamphlet, giving suggestions as to what materials are employed and their physical characteristics. He had found this very useful in estimating on work, and it would be valuable to almost anybody who should send for specifications and blueprints.

SECOND MUNITIONS SESSION, THURSDAY MORNING

As a result of the discussion at the first session on munitions, a committee was appointed to draft resolutions upon the questions of gages and standards; coöperation among manufacturers in supplying information and the status of men who are serving the country in the industries instead of at the front. These three sets of resolutions were reported at the third session by the committee consisting of: Luther D. Burlingame, *Chairman;* John H. Barr, J. B. Doan, A. J. Baker, Reuben Hill, H. L. Coe, Harry E. Harris and C. B. Hamilton, Jr.

The larger part of the third session was occupied in the discussion of these resolutions, each set being considered

[illegible] and were finally approved [illegible] below.

RESOLUTIONS RELATING TO [illegible] STANDARDS

WHEREAS: [illegible] experienced in other countries [illegible] the production of munition work and [illegible] manufacturer, and its consequent shortage of labor and material due to lack of control of [illegible] standard gages of measurement; and

WHEREAS: Great Britain, Canada and France have found standardization [illegible] essential for both Army and Navy [illegible] uniform and reliable results, and have [illegible] established an efficient organization which has proved [illegible] in overcoming these difficulties; and

WHEREAS: Increased efficiency of our manufacturers would be promoted by the establishment of proper standards of measurement;

BE IT RESOLVED: That the Congress be urged to appropriate sufficient funds for expenditure through a suitable agency, to provide standards and adequate means of calibration, distribution and supervision of such standards, including means for calibration of working and inspection standards in the different centers of munitions manufacture.

Also that provision be made in this appropriation for the establishment of a central office for the collection and dissemination of information on the methods of manufacturing munitions and other supplies.

RESOLVED: That this Society endorses any efforts tending to promote the ends outlined above, and in view of the imperative needs of the present situation, most strongly urges immediate action.

RESOLUTIONS RELATING TO COÖPERATION BETWEEN MANUFACTURERS

WHEREAS: It is the patriotic duty of every manufacturer to facilitate and expedite the manufacture of munitions and other supplies for the Army and Navy;

BE IT RESOLVED: That an appeal be addressed to all manufacturers and engineers to coöperate in the dissemination of information and the interchange of data pertaining to methods of manufacture, systems of organization, design of tools, operation layouts and time studies, including what is generally known under the term "shop secrets" so far as they pertain to munitions manufacture.

RESOLUTIONS RELATING TO STATUS OF MEN IN THE INDUSTRY

WHEREAS: It is necessary to obtain the entire patriotic coöperation of every man who can contribute to the furnishing of military and naval supplies;

BE IT RESOLVED: That we urge upon the Government the necessity of indicating in some way the value and loyalty of men in service in the industries whose occupation is essential to the production of war supplies.

DISCUSSION OF RESOLUTIONS

In introducing the subject of the resolutions President Hollis said that many other people in this country were passing resolutions to be presented at Washington, as a result of which there were so many lines crossing one another that it would be necessary and desirable before transmitting them to determine whether they would interfere with any action on the part of our Government or by agents representing the Government. The intention would be to discuss them at Washington with the officials there and the Munitions Board, in order to find how effective they would be in bringing about the end which all were hoping would be achieved.

The first set of resolutions, as originally presented, contained a reference to the serious delays which had been experienced in Great Britian and Canada in the production of munitions work, and to the desirability of increased efficiency of American manufacturers "in competition with foreign manufacturers."

Calvin W. Rice, Secretary, suggested that instead of speaking of England and Canada by name, the resolutions should not specifically state what countries it was desired by inference to improve upon, but that the general expression "other countries" be used.

John H. Barr said that in referring to England and Canada we were not reflecting upon them but instead were complimenting them upon the successful handling of a difficult situation. He felt that the resolutions were a great deal stronger with the names of these countries mentioned.

John Platt objected to phrasing the resolutions in a way to indicate that this country was in competition with other countries in munitions work.

Secretary Rice agreed with Mr. Platt, saying that a large number of people in this and other countries thought our entrance into the war indicated the prosecution of a dollar war, which it was not. The President of the United States emphasized in his proclamation that we sought no benefit, direct or indirect, and he felt that the strength of the resolution would be increased by the omission of any term indicating competition, even though we failed to get immediately the results we were after.

Fred H. Colvin said that in presenting resolutions such as was contemplated, the Committee should be appreciative of the condition which existed at the present time with respect to the Bureau of Standards, because of the difficulty which the Bureau was having in securing the appropriation needed for their work. With regard to the gaging of munitions, for example, they were going at it in a thoroughly practical way. Only last week their appropriation for gaging was struck out of the Committee's bill in the Senate, because our learned senators said that gaging had nothing to do with war!

There was some further discussion of phraseology, and a sharp difference of opinion was expressed by several as to whether, when speaking of manufacturers of this country, they should be designated as "*American* manufacturers," or as "manufacturers of the *United States*."

The first set of resolutions was finally approved as printed above.

With respect to the second set of resolutions, there was some discussion as to whether they were sufficiently specific in their phraseology, but they were finally approved as originally presented by the Committee.

The third set of resolutions, relating to recognition of those who sought to serve the country through work in the industries rather than in a military way, led to a discussion of the best way to accomplish such recognition.

President Hollis thought it very essential that recognition be given to those engaged in the industries useful to the country in time of war. For instance, this might be by an exemption board appointed in every state which would issue to persons in the industries exemption cards indicating that the persons holding them were exempt from service in the army by authority of a board duly appointed by the President of the United States.

Frank B. Gilbreth said the day had gone by when the only man to be recognized was one who was dodging bullets. While it might be rather revolutionary from our standpoint, he believed in the method adopted in Germany of a recognized industrial army which wore a designating uniform by which a man's status was determined, rather than by a certificate or by something in his buttonhole.

Reuben Hill declared that American workmen would not wear a uniform, even if they could get it for nothing. The practice in other countries was to give them a button. In Canada girls wear badges with a silver bar for six months' service, for which, after the close of the war, a more permanent decoration would be substituted. The man who returned from the trenches wore a button to show that he had been there, until such time as he received a medal for his service. It was not found possible even to prevail upon returned soldiers to wear their uniforms when they went into the industries.

Mr. Hill further stated that if certificates were issued, they should be endorsed by the concern by which the man was employed, showing his rating and pay. He instanced cases where men had left one firm and passed themselves as experts in seeking employment elsewhere, when, as a matter of fact, they were greatly exceeding their abilities in the claims which they made.

In concluding the discussion previous to the approval of the third set of resolutions, President Hollis said that he had had a hand in drafting them and that they were for the purpose of answering questions such as had been asked him very many times and upon which he had received letters beyond number, to the effect that a man wanted to know if he went into the industries how he could make it plain that he was not a "slacker." He asked who was to indicate to him the relative value of military service and of service in the industries. He had told many young men to stay where they were, doing useful work, but of course that was unofficial and he had no authority for giving such advice. It was his opinion that if there were some Government agency to give such advice officially, it would reconcile those of our citizens who felt uneasy about the matter in cases where they were for any reason exempted from military duty.

F. A. Waldron at the conclusion of the discussion of the resolutions said that because the engineer did not take sufficient interest in political matters, as a general thing he did not figure in public affairs as he should, and often got "the small end of the stick." He thought it would be desirable to outline a plan by which through united effort his services would be sought and his work recognized. With this end in view, he submitted resolutions calling for the establishment of a clearance bureau for information on the manufacture of munitions, which it was voted to refer to the Council of the Society with power.

ADDRESS BY MAJOR P. S. BOND, U. S. A.

Major P. S. Bond,[1] who attended the meeting as a representative of the United States Army, said that he was a civil engineer and not an expert on the subject of the manufacture of munitions, and that he would not attempt to speak upon topics with which his hearers were more conversant than he, but that instead he would refer to certain broad subjects in connection with our entry into the present war.

He said there was a tendency on the part of people entering upon something that they had never done before to go to extremes, to lack a due sense of proportion, to fail to separate the things that counted from those that did not count. He had been in the military service long enough to realize the fact, which he emphasized as the keynote of his remarks, that the spirit which actuated man, the spirit of pride in his efficiency, the spirit of wanting to do things, counted for a great deal more than mere knowledge of details.

During the previous discussion reference had been made to the subject of "slackers," and the status of the engineer who sought service in industrial work rather than in military duties at the front. Commenting on this, Major Bond said that under the voluntary system which had been characteristic of our military policy, or lack of policy, since the early days of our history, service to our country had been voluntary and in consequence inefficient. Now we had done away with the voluntary system and recognized the principle of the universal obligation of the citizens to serve their country—the principle of universal service, which was the only intelligent and efficient plan.

Under the system of universal service there was no such thing as the slacker; he became extinct with the ending of that system. The Government would call the men and select those best suited for military service and the men who were not thus selected certainly were not to be called slackers. They would render service of a different kind. The term slacker, he said, was concomitant with the voluntary system.

Continuing, Major Bond took up the main theme of his address to the effect that his mission was to help his country a little bit by attempting to instill into his hearers the need for the spirit of accomplishment, and the following extracts are taken from his remarks. He said in part:

"I have every confidence in the knowledge of details possessed by the engineers present in respect to the tolerances of the munitions business, the heat treatment of steel, and all such matters. If a man were selected for service in this work, as a matter of course the Government would be interested in the extent of his knowledge of details, but it would be much more interested in knowing whether he had the spirit of doing things or whether he was the kind of man who did not do things.

"To illustrate, there are two kinds of quartermasters in the army. First is the man who is very familiar with all the duties of a quartermaster, the man who knows all the rules and regulations governing just what the quartermaster is supposed to do and what he is not supposed to do; and second, the man who knows comparatively little of the regulations but who goes ahead and does things, because he does not know that he cannot.

"Therefore, unless you as engineers have this spirit of coöperation, or this willingness to do things, your detailed and intimate knowledge of your affairs may be an actual stumbling block to the country. What we ask and need of you is disciplined conduct in the German sense. When a German is asked to do something, he almost automatically does what he is called upon to do, because Germans have been disciplined for generations. The American, on the other hand, has a great deal of individualism; and now is the time when we want to ask him to control that individualism to some extent. When an American is asked to do anything—and this is true of mechanical engineers as well as of all other classes of Americans—he will very often start off by showing that what he is asked to do is absolutely unnecessary; but that if it must be done it better be done in a different way from that in which he was asked to do it. He will then remind one that the business should have been started two or three years ago, anyhow.

"Now we know that we should have started to prepare for war three years ago at the outbreak of hostilities; in fact, that we should have prepared ourselves 30 years ago—but we did not do it! And it is just as much your fault as ours! We

[1] Corps of Engineers, U. S. A., Cleveland, O.

know we have been wrong, but let us get busy and see what can be accomplished to make up for the time that has already been wasted."

Speaking more directly of the war, Major Bond expressed the belief, which he said was common with all military men, that Germany has drawn us into this war with a purpose. He believed that that purpose was to make a separate peace with the Allies at any terms they might ask, provided she were permitted to pursue her conflict with the United States and make us pay every cent that the war had cost her. Continuing, he said:

"The first thing that America must realize is that the country is at war. This may sound foolish, yet what indications is there that we are at war? We see something about war in the newspapers, but we do not realize what the war means because we have faced nothing comparable with it in all our existence.

"Ancient war was fought by a small handful of men trained for that particular purpose. A group of knights from one nation met a group from another nation, and on the outcome of their conflict depended the fate of one or the other nation, all the common people accepting the issue of the conflict because they were not able to oppose the knights.

"How different is the situation of the present day! Instead of a handful of men to do the fighting, war is now a whole nation's game; the entire strength of the nation goes into the conflict, she puts forth every ounce of effort, moral, physical and intellectual. This is well expressed by the title of a recent book, The Nation in Arms. That is what modern war means.

"The science of war is the most complex of all sciences, because it represents the sum of all sciences. There is no science known to mankind, from astronomy to bacteriology, that has not found its application in modern warfare. We are used to big business, but we do not realize that modern war is the biggest of all business.

"The romance, the glittering panoply of the knight and the crusader have been taken out of war and it now has become a matter of cold-blooded business conducted on a strictly business basis and governed by the same laws of cause and effect that rule in all business enterprises.

"In the Civil War some of our greatest battles covered a frontage of five or six miles; today the frontages extend from the North Sea to Switzerland, and from the Gulf of Riga to the Mediterranean Sea. Battles were fought in the Civil War by armies of 100,000 men; today there are millions of men engaged. The modern French '75' can fire 30 shots a minute—as rapidly as the modern rifle; the modern machine gun can fire 1000 shots a minute.

"In the Boer War the British fired about a million shells. Today the Allies on the western front are firing a million shells in a single day. The Frankford Arsenal, working three shifts of eight hours each, can turn out 16,000 shells a day. A single regiment of field artillery (24 guns) could fire this number in one day. A million shells means the product of sixty Frankford arsenals, which indicates the problem that we have before us!

"The dearest hope in the hearts of Americans is the hope of getting something for nothing. We have always sought to evade the issue, and our unearned success has lulled us into a sense of false security. We have hoped that the war could be won by some brilliant invention and without sustained and unwearying effort. All of us have hoped that some one would invent a machine that would save the country from having to send its men to war; but it is my opinion that the way to evade the issue successfully is to be fully prepared to meet it; and it is up to the nation today to put itself in that position.

"The men who have been called from civil life to assist in the mobilization of our industries are hard-headed, practical, common-sense engineers and business men. Their accomplishments, training and standing in the profession entitle them to unqualified support. Mr. Frank Scott, chairman of our Munitions Board, says that the Departments of our Army and Navy are too serviceable to be thrown over and entirely replaced by new civilian bodies. He regards it as the duty of civilians to coördinate the efforts of the Army and Navy and the great industrial forces of the nation.

"Our Ordnance Department has labored long and earnestly, in spite of discouragements, lack of money and popular support. It has labored incessantly, with insufficient funds and insufficient facilities, and yet has kept abreast, and a little more than abreast, of the progress of the art of war. Some of the notable contributions to the science of war have been made by our own ordnance experts, both civil and military. Among these are the disappearing gun, machine and automatic guns, the highest-powered guns in the world, automatic pistols, many devices for range finding, etc., etc.

"There have been no new effective machines introduced into this war. The 42-centimeter guns of Germany were in existence before this war. All the weapons of this war, including the aeroplane, were in use in previous wars, although of course they have been developed and brought to a higher stage of perfection in this war." (A voice: "What about the tank?") "There have been a number of devices, including the 'tank,' which I think is an adaptation of the motor vehicle, and the 'flammenwerfer.' These devices can hardly be dignified by the term 'new arms of warfare.' One does not hear very much now about the 'flammenwerfer' and the 'tank'; but he does hear a great deal about the fire of the '75,' which was invented before this war. We need not look for any sudden developments or new machines to save us. If we attempt to discard all the painstaking study of our Ordnance Department and pin our faith on new and untried devices we will assuredly come to grief.

"Our own Ordnance Department has been conducted on a comparatively small scale heretofore; but we must not hesitate to enlarge upon this; reduction of first cost in war times is no economy. A shortening of this war by even a few days means saving many millions of dollars and many valuable lives, including those of our own countrymen; therefore, let us not count the cost if only we can secure results. It is the function of the engineer to take up the military work of our ordnance experts which has been carried on over years of patient study and research, and to put their military methods on a commercial basis.

"I ask the engineer to get out of his head the idea that the ordnance experts of our army are narrow-minded pedants, that we are hidebound, or out of date, that we do not have commercial sense or commercial spirit. We want the engineer to work with us and bring his knowledge, not to confound or to supersede, but to aid ours, and together we will get results.

"A typical instance that will throw some light on this is that of a contract let for the construction of some wheels for artillery gun carriages. The man who secured the contract was an old wheel maker, who had been at the work all his life and thoroughly understood the business of wheel making from the manufacturer's viewpoint. He complained about the specifications, terming them 'foolish.' The specifications

demanded that the tires should be of a certain grade of higher quality steel than he had been using for tires; and he said to himself: 'Those fools up there in the Ordnance Department, fellows that sit at their desks and design these things, know nothing about commercial affairs or about the construction of wheels, and that is why they have made up these foolish specifications, and I am expected to stick to them.' So he came up to the Ordnance Department to complain about it. He said, 'Why cannot you accept such and such a grade of steel for the tire, milder steel than you have specified here? Why cannot I use good commercial standard steel such as I have always used, instead of that high-speed steel that some foolish ordnance expert has put in there?' And the ordnance expert at once pulled out a record of tests extending over a period of five years, to show the contractor that the durability of the steel that the specifications called for was about three times that of the grade of steel which he proposed to furnish, and that the weight called for was much less. And he explained the importance of weight. The contractor was convinced, and he went off and made the wheels according to the specifications.

"Another example Mr. Scott told me of himself. He had noticed that the specifications of the Ordnance Department called for a certain amount of nickel alloy in the rotating bands of certain projectiles in which the English use pure copper. Now the nickel was somewhat expensive, relatively speaking, but the greatest trouble was the time and the difficulty of obtaining the alloy. Mr. Scott went to the ordnance people and asked why they wanted the nickel alloy instead of the pure copper band? He did not take the attitude of the wheel manufacturer, because he had confidence in the Department, but he asked to know the reason why they could not use the copper band. It was explained to him that it would be contrary to the genius of our Ordnance Department, which is as progressive as any in the world; that their ingenuity and skill had been directed toward the development of very high pressures and very high muzzle velocities, so that our guns of any given size were more powerful than the guns of other nations; and that a copper band was not strong enough to stand up under the resulting stresses. 'And now,' said the ordnance experts, 'If we used the copper band it would prevent our following out our plans, and we either must have the alloyed band or else devise a different and inferior type of ordnance.'"

In conclusion, Major Bond said that modern war meant the application of engineering science to armed conflict. It was primarily an engineer's undertaking and was more that of a mechanical engineer than of a civil engineer. He hoped his hearers would get into their souls the spirit of service and prepare to do what they would be called upon to do without argument, without cavil, without hesitation, criticism or fault finding. "You are called upon to help," he said, "to help with all your hearts and souls and to remember how much it means to our country in the matter of saving the lives of our own citizens. The furnishing of an ample supply of munitions means saving the lives of those you love, therefore for your country's sake turn to and do all that you can. Do not count the cost, do not hesitate."

PRESENTATION OF PAPERS ON TOLERANCES, GAGES, ETC.

Following the address by Major Bond, the last four papers of the meeting were presented. These were given either in brief abstract or by title, owing to the short time available, and were as follows:

Procuring Materials for Munitions, C. B. Nolte.

Limits and Tolerances for the Manufacture of Munitions, A. W. Erdman.

Gages and Small Tools, Frank O. Wells.

The Importance of Intelligent Inspection in Munitions Manufacture, E. T. Walsh.

CONCLUDING DISCUSSION

Major P. S. Bond in discussing the paper on Inspection in Munitions Manufacture by E. T. Walsh emphasized the importance of closeness and accuracy in shell manufacture. He said this was essential, particularly since the adoption of the moving barrage, which had been the secret of the success of the Allies on the Western Front. This method of firing was first successfully employed by General Nivelle and was the occasion of his being elevated to the supreme command of the French armies. The idea of the barrage was to advance the range by certain intervals by the clock, so many yards per minute. The infantry followed immediately behind the barrage, so that as soon as the barrage had passed over the space immediately in front of the trenches, the advancing force was ready to jump in at once before the enemy could come out. Formerly they had to traverse a considerable distance after the barrage was lifted, which gave the enemy an opportunity to come out and oppose them by bringing his machine guns into action.

In the use of the barrage it was found that if there was an error in the bursting point of the shrapnel of even as much as 25 yards, it would result in the killing of great numbers of the attacking force; in fact, it was looked upon as inevitable that a certain number of the men would be killed by the barrage, and a sergeant in the English Army describing to an American such a situation remarked that, "Shorts are very annoying, sir, very annoying, indeed!"

Major Bond said that there had been a great deal of complaint on the part of the Allies about shorts in the shrapnel fire and in high-explosive shell fire. He also called attention to recent occurrences of premature or faulty explosions on our armed ships. There had been a number of instances in the Navy, and a great deal of complaint about the imperfect manufacture of shells. Too much importance could not be placed upon the necessity for accuracy in the manufacture of shells.

Major Bond concluded the technical discussion of the session by urging that we be lenient with our War Department, just as we expected the War Department to be lenient with those, in the membership of the Society for example, who might hold preconceived ideas with respect to the production of munitions. It should be remembered that Germany's system of defense had been under way ever since the Battle of Jena in 1806, at which time Napoleon imposed upon Germany the restrictions that caused her to develop her present scheme of national defense, which has proved thus far to be of great effectiveness.

Now we had this war dumped on us overnight, as it were. We had, comparatively speaking, "a tiny little War Department" which simply was not adequate to the situation. It was literally swamped with duties suddenly thrown upon it. Major Bond urged the engineers present to be patient and said that "the one certainty is that we are all going to be called on for service. Whenever the department wants experts along certain lines this Society, or some other society such as this, will be asked to designate the men who can do the work."

GAS POWER SESSION, THURSDAY MORNING

At the Gas Power Session, held under the auspices of the Society's Sub-Committee on Gas Power, four papers were presented and discussed. Prof. William T. Magruder and Mr. [illegible], both members of the committee, acted as chairman and secretary, respectively.

PROFESSOR JUDD PRESENTS PAPER ON FIRE-ENGINE TESTS

The first paper presented was by Prof. Horace Judd, entitled Test of a Motor Fire Engine, and contained the results of a test of a Seagrave motor fire engine having a 4-cycle, water-cooled, six-cylinder motor, 5¾ in. cylinder bore by 6½-in. stroke, 79.3 hp. by A.L.A.M. rating. The motor operated a two-stage centrifugal pump with balanced end thrust.

The maximum capacity was found to be 745 gal. per min. at 122 lb. pressure at discharge of pump, with 2-in. smooth nozzle and 250 ft. hose line with Siamese union. Gasoline used per hour, 0.218 gal. per hp. at rated load.

With coal at $2 per ton (2000 lb.) and gasoline at 25 cents per gal., the cost of producing a fire stream with the motor fire engine is four times that with a steamer. As compared with the horse-drawn engine, the motor engine can reach a fire in half the time, is readily converted from locomobile to pumping engine, is more easily and economically operated, and eliminates entirely the expense of maintaining horses for transportation. Its duty is nearly six times that of a steam fire engine.

A written discussion of this paper was contributed by Claude M. Garland, and it was discussed orally by E. W. Roberts, and the author replied. The discussion follows:

Claude M. Garland stated, in a written discussion, that the motor fire engine, like many other pieces of apparatus, does not depend for its success upon thermal efficiency or fuel economy. The results in the paper indicate, however, a combined thermal efficiency from engine to water horsepower of approximately 10 per cent, which would doubtless indicate a thermal efficiency of engine of something like 20 per cent. This is a very satisfactory performance.

The differences in fuel costs, as shown in the paper, between the steam- and the motor-driven engine are, however, hardly representative of actual conditions. It is seldom necessary to pay 25 cents a gallon for gasoline; eighteen cents is probably an average figure. It is hardly probable that coal suitable for use under the boiler of a fire engine can be obtained for $2 a ton; $4 would probably be more nearly an average figure.

As the fire engine is seldom in operation for more than a few hours a day, the item of fuel cost is undoubtedly negligible when considered with the advantages of high speed in travel, the saving of time in starting, and the elimination of feed and upkeep on horses.

E. W. Roberts[1] pointed out, as a matter of interest, that no horse-drawn fire apparatus is being built today, and none has been for several years. A few steamers are being built, but they are all drawn by gasoline tractors, and these are gradually being replaced. As rapidly as possible, all the cities in the country are installing motors. The motor-power apparatus is rapidly succeeding the horse everywhere throughout the country.

The chairman thought the paper might be considered as a foundation paper, from which to judge future performances of motor-driven fire engines.

Professor Judd, in closing, said it might be well to point out that the unit was operated entirely by the fire department and fireman operators. Those who conducted the tests had nothing to do with the adjustment of the motors or anything else pertaining to the engines. All they did was to look after the accurate measurement of the fuel and the water pumped. The results presented may therefore be regarded as average results for the type of engine tested.

[1] Consulting Engineer, Cincinnati, O.

MOTOR-TRUCK ENGINES FOR LONG LIFE

The second paper, entitled The Design of Motor-Truck Engines for Long Life, by John Younger, was presented by the Secretary in the absence of the author. A brief synopsis of the paper follows:

The problem of long life of a motor-truck engine is not a simple one, on account of the widely varying conditions under which the engine operates.

Long life depends on three factors: Design, manufacturing excellence, and operating conditions.

Design: Under this head the paper summarizes present practice, giving particulars of recommended materials, dimensions of parts, and factors of safety for the several parts of the engine.

Manufacturing Excellence: Workmanship, tolerances, and running tests are considered. For long life the best workmanship is essential.

Operating Conditions: Recommendations for maintaining the engine in first-class condition are given. For long life particular attention should be paid to lubrication, cleaning, inspection and regulation.

Contributed discussions of this paper were received from H. S. Whitten and H. E. Morton, and the paper was discussed orally by E. W. Roberts and Kaufman T. Keller.

F. A. Whitten[1] wrote that he believed that operating conditions had more effect upon long life of truck engines than design and manufacturing excellence combined. The motor-truck manufacturer, unfortunately, had practically no control over the operating conditions. He had applied governors, screens, and other devices in an endeavor to protect his machine from abuse, but drivers did not like them.

Generally speaking, owners had no workable system to determine whether the manufacturer's devices were being used or his instructions carried out. Any investigation along this line was usually of the sort which resulted in locking the barn door after the horse was stolen. A tremendous amount of education of the owner was required in order to attain proper results. The first trucks a man used were frequently condemned as unfit for the service because of the way in which they were operated. We had very little difficulty with trucks in the hands of those who had had previous experience in operating, as such owners had usually already learned their lesson from the results of neglect and careless handling.

As the author stated, "oil and lots of it" was one of the principal features of successful operation. Actual breakages were rare, and lubrication troubles were responsible for most operating troubles and delays.

The carburetor was not usually considered a part of the

[1] General Motors Truck Co., Pontiac, Mich.

engine, but Mr. Whitten believed it should be so considered, as the success or failure of the engine depended upon the carburetor in more ways than was generally recognized. Investigation would show that present-day lubrication troubles were usually intimately related to the carburetor and fuel. That the low-grade fuel generally used today was responsible for many troubles was a fact not generally recognized by operators.

The driver should not be given control over the carburetor adjustment except to a very limited degree. Choking the air supply to produce a rich mixture for starting might be necessary, but forcing the engine to pull its load before it was warmed up might be a very expensive procedure if persisted in. This rich mixture, with present grades of fuel, was almost certain to carry into the cylinders a certain amount of fluid fuel which destroyed the oil and resulted in piston-ring and cylinder wear. This liquid fuel also worked down past the pistons and destroyed the lubricating oil in the crankcase. Not only was the oil spoiled in this way, but the liquid fuel loosened small particles of carbon dust and carried this down into the cylinders and the crankcase, from whence it would be distributed into the bearings in spite of any screens which might be provided. By the use of a rich mixture, either in starting of the truck or by bad all-around carburetor adjustment, it was possible to wear out a motor in a very short time.

The danger of this sort of operation was self-evident to any engineer, but it seemed very difficult to get the user to appreciate the necessity for care of this sort or to believe he was in any way responsible for troubles caused by such operation.

H. E. Morton discussed the lubrication of an internal-combustion engine of the multi-cylinder so-called high-speed class, which, he stated, involves a variety of problems. The conditions were severe, and in most cases the engines received little attention, so that the real successful system had to be reliable, self-contained, efficient and fitted with indicating devices to give early warning of an exhausted oil supply or irregularity in operation.

The three systems most used were full splash, full-forced and a combination of the two. The individual pump and distributor system was seldom employed on modern engines. There seemed to be no special merit in the full-splash system except low cost. The full-forced and combination systems were both good, but the former, properly designed and applied, would give excellent results, and had the great advantage of making possible the highest unit bearing pressures all through the engine. The belief had existed in the minds of some that this higher loading was made possible by a sort of counterbalance equal to the oil pressure, but there was little to substantiate this theory. "Forced volume system" might be a more significant name for the system, as tests indicated that it was the volume of oil forced through the bearings which was most important. The volume of oil rapidly carried away the heat generated, immediately replaced a break in the oil film, due to momentary heavy loading, and thus allowed the use of very high unit bearing pressures. All the above-mentioned systems made use of what might be loosely termed splash for cylinder-wall lubrication.

To make any one of these systems practical it was necessary to use the oil over and over, passing it through suitable filters each time, of course. Also for ordinary-duty engines all the oil was carried in the lower part of the crankcase. These conditions meant that a great deal of loose carbon was washed into the oil, and as it was so fine that the ordinary wire gauze would not remove it, the pump continued to pass it through the system. This particular point should not be lost sight of, for the carbon particles were quite effective as a lubricant and tended to hold up the viscosity of the oil. A good mineral oil under such conditions appeared to lose very little in lubricating value after long use, especially if occasionally well filtered.

For exceedingly-high-duty engines, such as those designed for aeroplane service, the practice of carrying all the oil in the crankcase was questionable. Oil temperature needed to be kept down, and with a secondary external circulating system and supply reservoir it could be fully controlled. Actual service tests covering many months showed that good oil could be used almost indefinitely, employing an external circulating system and carrying very little oil in the crankcase.

E. W. Roberts[1] said one or two points in the paper were rather astonishing to him, and quite against his experience. A clearance of cylinder and piston of 0.002 in. was generally considered by manufacturers far too large. He believed that such large tolerances were a mistake, because the workmen were apt to get careless. He had never heard of a tolerance for a cylinder or piston of over 0.001 in. He thought that while larger tolerances could be allowed, but tolerances of 0.0005 in. made the men more careful.

He disagreed with the author's contention that spiral oil grooves would be found preferable for bearings. He said that one of the greatest mistakes made by manufacturers of engines of all kinds was in the shape of the oil grooves in the bearings. Experiments made at Cornell by Bierbaum nearly twenty years ago, showed that the proper form of oil groove was the H-groove and not the spiral groove or the X-groove. In engines having lubrication troubles, or hot bearings, if the change were made from the spiral to the H-groove the trouble would generally disappear.

Referring to the general idea that carbon was produced by the lubricating oil, this speaker said that it was not generally recognized that an over-rich mixture was quite a prolific source of carbon, because in such a mixture there was a tendency for the hydrogen to combine with the oxygen: that was now proved experimentally in a number of ways. But the general idea prevailed that all carbon was due to lubricating oil, which is not altogether true.

E. E. Keller discussed the author's statement that "When the oil gets dirty, say, every three hundred miles or so, it ought to be thrown out and replaced with clean oil." In his experience in the testing of engines, he had found that the oil could be used over and over again. It was not necessary to filter it, but by running it through a cream separator the heavier particles of matter that had accumulated in it could be taken out, and the finer carbon or graphite was very beneficial to the engine. He had found, however, that oil used over and over contained considerable muck or gummy substance, which collected in the bottom of the oil can, and which was sometimes due to water getting down and breaking up the oil, or particles of dirt getting in.

Regarding tolerances for cylinder and piston, he differed with the author, and thought that pistons on the high limit should be put into cylinders on the high limit, and pistons on the low limit into cylinders on the low limit.

MR. YOUNGER REPLIES

Mr. Younger, in his closure, said that Mr. Roberts had stated that the clearance of 0.002 in. was generally considered by manufacturers far too large. He did not understand where he got this impression, as in dealing with motor-truck engines of 4 to 5 in. bore, a *maximum* variation in clearance

[1] Consulting Engineer, Cincinnati, O.

of 0.002 in. could be allowed, and it was certainly inadvisable to come below a clearance of at least 0.003 in. on the skirt of the piston, preferably, in accordance with his experience, 0.001 in. per inch diameter of piston.

He thought that in Par. 12 he should have been a little more careful in explaining exactly what was meant by a process of selection. It simply meant, however, that while cylinders could be ground to a maximum tolerance of 0.002 in. and the pistons finished to a similar tolerance, a total tolerance of 0.004 in. should not be allowed in the engine, but that, as stated, pistons on the high limits should be put into cylinders on the low limits. This held for the rest of the engine as regarded connecting rod bearings, etc.

If Mr. Roberts would refer to the paper, he would see that on connecting rod bearings the bearings should be grooved with a slightly spiraling oil grove, to prevent ridges wearing on the crankshaft. This was not at all the figure 8 oil groove that probably Mr. Roberts was thinking of, but was simply a one revolution spiral of a pitch very slightly in excess of the width of the groove. This had been found in combination with labyrinth checks to be exceedingly satisfactory. The H-groove was, as far as he knew, obsolete in automobile-engine practice. Quite a number of firms were using successfully no grooves at all.

He feared that he would have to disagree with Mr. Keller entirely. Oil at the rate of one gallon every two or three hundred miles was so cheap that it should be thrown away, and filtering or separating need not be resorted to.

It must be remembered that the great majority of motor trucks were running in places where mechanical separators could not be easily obtained, and it was very questionable if the labor and cost involved in separating a gallon a week would be worth the trouble. Experience had distinctly shown, beyond all question, that the safest, most reliable way was to throw away oil every two or three hundred miles and replace entirely with clean oil.

Mr. Keller gave away his case entirely when he stated that he noticed considerable muck or gummy substance accumulating in the bottom of the oil pan. This was due to water getting into the oil and products of combustion; also, in cold weather the rich mixture that was used in the carburetor, to get the engine warmed up, would cause an excess of gasoline to drain past the pistons into the oil, and accordingly waste the oil.

Mr. Whitten rightly emphasized the point that operating conditions had a great deal of effect on the long life of truck engines. Designers and manufacturers had still to go a long way in order to make their machines fool-proof against even the most stupid operators. However, in all fairness to truck drivers, it must be stated that the last two or three years had seen very considerable improvement, and the average truck driver today was a reasonably intelligent operator.

DESIGN OF GAS ENGINES DISCUSSED BY MR. DUPRIEST

A paper entitled The Relation of Port Area to the Power of Gas Engines and Its Influence on Regulation, by J. R. DuPriest, was then presented.

In this paper it is stated that any system of connecting up the governor of a gas engine to the throttle valve which gives equal changes in port area for equal changes in the governor speed, will make the regulation of the engine very sensitive at light loads and too slow at heavy loads.

The object of this paper is to present a method of determining the port area required for any fractional load on a throttling gas engine operating on the four-stroke cycle, and to suggest a means of admitting the fuel so as to get the same degree of speed regulation throughout the full range of load.

The author has made an extended study of the working of a $16\frac{1}{2} \times 24$-in. horizontal double-acting tandem throttling engine, running on natural gas at 180 r.p.m., and from a consideration of the data obtained in tests and the characteristic curve of the governor used has devised a method by means of which the relation between the travel of the governor collar and port area for a given power can be determined. A governing mechanism may then be designed which will give equal changes of load for equal movements of the collar, or the ports may be so shaped that equal changes in governor-collar travel will give equal movements of the valve, but at the same time give the proper port area for equal changes in power delivered.

THE PROBLEM OF AEROPLANE-ENGINE DESIGN

The fourth and last paper of the session was that by Charles E. Lucke, entitled The Problem of Aeroplane-Engine Design.

The paper resolved the engine into a light, high-tensioned steel structure, consisting of seamless tubing and forged or welded steel parts, possibly formed in drop-forge dies. To this steel stress structure are added certain members, such as the piston, exhaust valve and guide, designed primarily for heat-flow conditions and not for stresses; and certain closing members, such as the ports for the intake and exhaust, which can be very properly cast in aluminum; and the oil crankcase closure, which can be made of any material desired.

This paper was presented by the chairman, who called attention to its salient points in the following words:

"Professor Lucke prepared this paper from an analytical point of view, and discusses the things which have been done and the outlook for the future whereby to reduce the stresses and decrease the weight per horsepower of aeroplane engines. He states that the air-cooled motor has entirely failed in comparison with the water-cooled motor, which will impress everyone. He considers the mixture quality of very great importance, and also the dryness and the homogeneity of the mixture. He brings out a point about the position of the spark plug, to the effect that the moving of the spark plug from a side wall to a center point will improve the power of the engine. He emphasizes the desirability of using the air meter for measuring the quantity of air supplied and regulating the horsepower. He advocates large diameters and short strokes for aeroplane motors. He states that cast iron is well enough to use, but we now have several methods of making aeroplane-engine cylinders in aluminum or sheet steel or of steel forgings, with cast-iron liners. He discusses the question of the arrangement of cylinders and valves. He takes up the construction of valves, discounts Grashof's formula, goes into the thermal capacity of valves and pistons, particularly, and advocates that the piston head should be made increasing in depth towards the wall of the cylinder to furnish a better means for the heat to pass off."

Written discussions of this paper were contributed by R. C. Carpenter, O. C. Berry, Claude M. Garland, H. L. Hornung, H. E. Morton, E. W. Roberts and H. M. Crane. Mr. Roberts presented his discussion in person.

R. C. Carpenter said that Dr. Lucke's paper should be read in connection with a paper by Neil MacCoull, Jr., presented before the Society of Automobile Engineers in June 1915. The two papers were in remarkable harmony on the principles

of design which applied, and the possible results which might be obtained, in the selection of materials.

The particular problems which had made the production of the aeroplane engine more difficult than internal-combustion engines for marine and stationary purposes were, without doubt, due to the important requisites of reliability, lightness, and efficiency, which requirements were conflicting to a greater or less degree, making it essential that the designer decide which requisite was to be considered the most important.

The question of reliability involved lubrication, carburetion, and all the problems relating to continuous operation. So far as Professor Carpenter could recall, there was no other class of engine in which the question of reliability was so vital for results. In the marine or stationary engine, failure of the engine to operate merely required repairs or adjustments which, although possibly inconvenient, could be made without endangering the entire supporting structure; this was obviously not the case should for any reason the aeroplane engine fail to run.

The use of a compression rod for valve openings was undoubtedly not theoretically correct, but it was giving good satisfaction in practice. The use of a tension rod or steel wire as suggested did not prove so attractive after the necessary mechanism was laid out.

Regarding valve timing, for high-speed engines he had closed the inlet valve as late as 45 deg. past the outer dead center. The best test of the inlet valve was the "flow back." A good plan was to set the valve closing so late that a slight "flow back" from the carburetor would be manifest and then reduce the lap just a few degrees.

In the matter of valve lifts, an increase in the number of valves permitted reduction of lift and reduced both the pounding and the inertia of the mechanism.

In his thermal analysis of the valve, the author had undoubtedly overlooked the flow of heat from the valve head to the seat. The exhaust valve was on its seat about two-thirds of the time, and experience had shown that if the seat was not cooled, valve trouble was experienced.

A misconception had existed among designers regarding the two functions of the piston. Professor Lucke pointed out the heat conduction. Another thing was the wearing surface. Short pistons and shuttle-shaped pistons—pistons with the bearing only on the ends—had insufficient bearing surface, which resulted in rapid wear and a piston slap early in the life of the engine.

A heavy piston was a very bad feature in a high-speed engine. We must keep our piston weights down to reduce the inertia effect. This was very essential.

Regarding the bolts for the cylinders, in his first aeroplane-engine design, made in 1910, he used long cylinder bolts passing through and beyond the crankshaft bearings.

In both papers steel was recommended as a substitute for cast iron, which was obviously a desirable change so far as the substitution might be practicable. In this connection, it would also seem to be of advantage to employ aluminum alloys as far as they proved themselves to be serviceable and reliable both because of the light weight and of the higher heat-transmission coefficient which such alloys had as compared with cast iron.

It was Professor Carpenter's opinion that the aeroplane engine was now passing very rapidly through a development period, and that a short time only would be required to fully disclose the essential requirements as to types, materials, and details of workmanship. These, he believed, would in a general way agree with those stated by Dr. Lucke.

O. C. Berry, in a written discussion, supported the author's point of the importance of motor efficiency and the part which quality of the mixture played in determining this efficiency, by giving the results of tests carried out in the laboratories of Purdue University for the specific purpose of showing the effect on the performance of a motor of changing the character of the mixture.

These tests showed that the most efficient mixture coincided almost exactly with the theoretically perfect mixture when the engine was running under load, and was considerably leaner than the most powerful mixture. For low-load conditions, the richer, more powerful mixture seemed to be more efficient as well, probably due to the fact that it fired more regularly at low pressures.

The tests also showed how very important it was that the mixture be correct if high efficiency was to be obtained. In this connection it was important to note that any change in the temperature of the air or the fuel flowing through the carburetor, or a change in the altitude, would change the character of the mixture furnished by a carburetor having a fixed setting. For this reason the carburetor should be furnished with an adjusting device which could be operated from the driver's seat. By such a means the mixture might be kept correct while the machine was in the air. The rule for the operator to follow was to make the mixture leaner until the engine lost power, and then make it richer, a little at a time, until the power was restored. The leanest mixture with which the engine would pull satisfactorily was the most efficient.

Professor Berry did not agree with Professor Lucke that drying the mixture was a sure cure for carbon in the cylinders. A dry mixture might be too rich and cause a heavy carbon deposit.

The aeroplane motor, like the racing motor, was designed to do most of its running at a speed and torque which were nearly constant. The best way to speed up the rate of combustion in such a motor was to increase the compression. The racing motors developed their best torque at about the speed at which the aeroplane motor was required to run, and gave their best power at nearly twice this speed. The rate of combustion and piston speed were therefore scarcely controlling factors in aeroplane-motor design.

The factor which limited the speed at which an engine could run continuously at full torque was the ability of the bearing at the lower end of the connecting rod to keep cool enough to permit proper lubrication. This was borne out by the experience of automobile-race drivers. An examination of the experience of several hundred cars entered in various races showed that many more engines failed due to crankshaft and connecting-rod trouble than due to piston trouble, and that valves did not cause half as many failures as crankshafts. To Professor Lucke's list of pistons and valves he would therefore add that the connecting-rod and main bearings on the crankshaft must be designed primarily for heat dissipation. The best way to accomplish this was to supply them with a copious supply of oil under pressure, and thus oil-cool them.

Claude M. Garland wrote that there were two points in the paper which his experience would indicate to be of first importance, not only in the design of aeroplane engines, but also in the design of all internal-combustion engines of the single-acting type. These were the design of the exhaust valve and the piston from the standpoint of thermal conductivity for the purpose of maintaining the temperature of these parts at such a degree as to prevent preignition of the charge.

The piston was the more difficult member to handle, and in most instances was the principal offender in premature-ignition

conditions. This was clearly illustrated in the testing of a single-cylinder engine which had given considerable trouble from preignition. On removing the plate which carried the spark plug immediately after a test, the piston was found to be at a low red heat. Some experiments were made on this engine for the purpose of determining to what extent the temperature of the piston affected on the premature ignition.

A small nozzle was located in the end of the cylinder, and an injector device provided whereby a very fine stream of water was discharged on the piston head on the opening of the exhaust valve. This not only cooled the piston head, but also the exhaust valve and the cylinder walls. In fact, sufficient water was injected to lower the temperature of the exhaust gases to about 500 deg. fahr. Under these conditions, illuminating gas, which normally could not be compressed to over 70 lb. without premature ignition, could be compressed to 250 lb. without any trouble whatever from this cause. The maximum pressure of the cycle approached 900 lb. per sq. in. Under these conditions the engine indicated a thermal efficiency approaching that of the Diesel.

While it was not possible to provide water injection for the cooling of an aeroplane engine, yet it was possible, as Professor Lucke suggested, to minimize greatly the troubles through proper design of piston and valves for the rapid conduction of heat.

H. L. Hornung wrote that Professor Lucke's analyses of the mixture question were fundamental with any fuel, but became particularly apropos with fuel having end points 400 deg. fahr. and above.

His conception of the straight portion of the m.e.p. curve was no doubt borne out by the inaccuracies of our testing methods, wherein small variables made it impossible to read slight changes in ordinates which must exist, producing a peak in the curve at some maximum point. It did not appear to be a mathematical probability that we should actually have a straight portion to the curve, which was the resultant of variables of a higher than first degree. Of course, for all practical purposes it might do no harm to consider a portion flat, but for the sake of future deductions, it appeared more satisfactory to think of the curve as seldom being straight at any point or series of points.

The author's discussion of arrangement of cylinders and jackets suggested a thermoanalysis of the motor by dividing it horizontally into layers $\frac{1}{2}$ in. in thickness, and laying out a curve with the layers as abscissæ and as temperatures ordinates in different horizontal-vertical planes. Such an analysis would open the eyes of most of us to a new realm of design, and would show why valves do not seat and pistons seize with apparently no reason. It would also show how far the crankcase might be brought up on the cylinder, which might be made with separate heads. Block cylinders failed through our lack of knowledge such as this analysis would give.

Later in the paper there was further evidence of designing from the thermal-stress standpoint. Without desiring to take issue with the author, laboratory investigations showed that heat flow was from the center of the valve to the seat and up through the stem, if the area was sufficient. Here came the question of stem diameter from the standpoint of heat conductivity and not wear. In valves running under high output there was a dark annulus on the outside corresponding to the conducting ability of the seat. The wider the seat, if it seated well, the cooler the valve and the wider the annulus; but the wider the seat the greater chance to catch carbon and the lower the effective area for a given lift. These were shop observations which did not seem to check the analysis of the text. A valve head did not always receive the same amount of heat on the outer edge, nor was the water cooling of the seat always uniform, all of which caused unusual distortions.

The author's thermal-stress analysis of the piston was a masterpiece. Attention should be called to the fact that the center of the piston head usually gave the trouble and controlled largely the cylinder bore for high outputs.

Thermal analysis of the cylinder illustrated the necessity of neglecting the lower regions of the flame-swept bore while giving unusual attention to the regions of the exhaust valve and spark plug. The tendency of this treatment was to bring about a more uniform temperature throughout the cylinder structure.

Sections on the design of the crankcase were certainly worthy of the attention of all engine designers, both from the thermal and dynamic standpoints. Most crankcases were deplorably weak, even in otherwise well-designed engines.

In closing, it seemed proper to accent the tendency so aptly crystallized in this paper of reverting to the fundamental conception of the fact that the internal-combustion engine was a heat engine and must be designed with this primarily in mind before the dynamic designing was done. This course had seldom, if ever, been followed in the past, but was the direction toward which real progress must be made.

H. E. Morton wrote that the paper stated that the ordinary aeronautical-engine piston today was a failure, and was, with the possible exception of the exhaust valve, a source of greatest trouble. While this might be true of some engines, he had for several years been having absolutely no trouble with pistons, and especially those of the aluminum variety. The problem of heat conduction through the piston was unquestionably of great importance, but he found that it was a comparatively simple matter to design a strong, light and also cool-running piston for even comparatively high-speed engines.

It was interesting to note the reference to the use of wire for actuating the valves. He supposed that was one of the first suggestions that came to the mind of a designer, but his experience had been that to incorporate neatly such a member was not a simple matter.

It seemed that Professor Lucke, for some reason or other, had omitted to mention the detachable-head design which was apparently growing in favor in aeronautical work. This design was certainly most convenient both in manufacture and field work, and was especially applicable in connection with aluminum cylinder jackets. The method mentioned in the paper of screwing steel sleeves into the aluminum was more or less expensive and troublesome, and a much simpler method could be resorted to where a detachable head was used. Aluminum heads with cast-iron valve seats were proving very satisfactory, and with a light steel sleeve shrunk into an aluminum casting this detachable-head design became extremely lightweight and accessible.

E. W. Roberts[1] wrote that the air-cooled motor was still a considerable factor in the aeroplane, and for certain classes of machines, like the fast scout, was still in considerable favor. So far as the 2-cycle engine giving way to the 4-cycle type was concerned, this would warrant the assumption that the 2-cycle was the original engine. The majority of the 2-cycles that have been offered for aeroplanes have been poorly constructed and poorly designed. The trouble with this type of engine was not so much with the type itself, but with the builders. It offered a solution of one of the most annoying problems of the aeroplane engine, the trouble with the valves. From 24

[1] Consulting Engineer, Cincinnati, O.

to 25 hours of cumulative flying was about all that could be depended upon from the 4-cycle aeroplane engine, and then it had to be overhauled, the valves reground and all adjustments remade. This phase of the problem had been prominent since the beginning of aviation. Lubrication had been fairly well solved, but in a rather complicated manner, in the 4-cycle type. Valve trouble in the 2-cycle was eliminated because there were no valves. Lubrication of the 2-cycle was simplicity itself because the oil was mixed with the gasoline. In actual flying, the 2-cycle had proved itself fully equal to the 4-cycle in all points but one, and that was fuel economy. This was a very important point, but if the same attention were given to the 2-cycle development as had been given to the 4-cycle, this part of the problem would be solved. As it was, the 2-cycle water-cooled motor did not use quite as much fuel as the air-cooled four-cycle for the same amount of power.

In the matter of carburetion, two conflicting phases of this problem were encountered. One was, we must heat the mixture to get perfect proportions, especially with modern fuels, and heating the mixture reduced volumetric efficiency. Internal-combustion engineers did not altogether agree with the statement that the explosion line on the indicator card must be maintained vertically for a maximum efficiency. Some engineers seemed to think that if the explosion line did not bend toward the expansion line, a certain amount of back pressure would be obtained that would cut down the efficiency. Personally, Mr. Roberts had never seen any data to prove this.

In the statement that curvature of the horsepower-speed line was due to a corresponding variation of volumetric efficiency, and also that at some high speed the horsepower-speed line fell before the volumetric efficiency, he would point out that the two factors of inertia effect of reciprocating parts and vibration in mass had considerable bearing on high-speed efficiency.

Regarding connecting-rod length, he had found the limit in practice was 1.8 times the stroke. While this would undoubtedly appear quite short to some engineers, it apparently gave good results.

He had used quite a number of cast-iron cylinders for aeroplane motors 1/8 in. thick, and had never had any trouble with them. There were several references in the paper to the use of aluminum for water jackets, and apparently for the combustion space. As a matter of interest, he might say that he had built something like 100 aeroplane engines with aluminum-alloy cylinders, and found that when making very extended flights with inadequate radiators these cylinders would break through in the combustion space. In all other respects they gave very satisfactory results.

Regarding valves, and particularly valves in the head, quite a number of engines had been made with a single valve opening into the cylinder which would admit of a very large area. There were several ways in which a single valve opening could be employed.

In conclusion, a feature of aeroplane-engine design that appeared to be overlooked by quite a number of designers was the crankshaft. There were two factors in this connection of great importance and yet quite frequently neglected. One was the length of the crankpin bearing and the other was the securing of lightness by using a hollow shaft. To replace a solid shaft 1 5/8 in. in diameter, he used a shaft 2 1/2 in. in diameter with a 2 1/4-in. hole. This not only decreased the weight to such an extent that a four-cylinder shaft 40 1/2 in. long weighed only 17 1/2 lb. when finished, but the large diameter of bearing reduced the oil-film pressure and practically eliminated overheating these bearings.

W. H. M. Crane, in a written discussion which will be published in full later, outlined the relative characteristics of motors for aviation service and for motor car service respectively. Regarding the aeroplane motor, he wrote that the one supreme requirement was that it should have the lowest possible weight per horsepower of continuous duty. The weight must include not only the motor and its ordinary accessories, but also the fuel and oil required for the length of flight desired. The limit of power that could be successfully used in aeroplanes had not yet been nearly reached, but already even the lower-powered machines had motors more powerful than all but a few motor cars, while the other military types of aeroplanes employed motors of a power entirely unnecessary in any motor-car service. The bulk of aeroplane motors would have piston displacements of 500 cu. in., or over, while there were very few car motors as large as 500, the average being from 300 to 400.

Not only must it be able to operate continuously at full load without distress due to overheating or other troubles, but it must also have as nearly as possible 100 per cent of reliability. This latter requirement was always present, due to the danger involved in a forced landing at some place unfavorable to landing.

It did not have to be particularly quiet, in view of the very considerable propeller noise. A very moderate amount of muffling of the exhaust and practically no attention to mechanical quietness would meet all the requirements.

Extremely long life in hours of operation, without repair, had not yet been required of aeroplane motors, although the time would undoubtedly come when this feature must be given more serious consideration.

Flexibility, as we knew it in the motor car, was not required in an aeroplane power plant.

Absence of vibration was of importance in aeroplane motors, but as only one full-load speed had to be provided for, the problem was considerably simpler than it was in motor-car engines.

In the aeroplane motor, the lightest possible materials were used, aluminum alloys and the higher grades of alloy steel being very largely employed; cast iron, which had given such valuable service in the gas-engine field, was out of the question on account of its weight. The design, as a whole, should be compact, and the number of parts as small as possible. Only in this way could light weight be obtained with the necessary strength and stiffness. Therefore many motors of the V-type or of the radial type were seen, such as the rotating air-cooled motors and the stationary Salmson motor. Block casting of the cylinders where possible was also a great help toward stiffness with light weight.

Efficiency in gasoline economy being so important, as well as power with light weight, the highest possible compression was employed, while valve-in-head motors were almost universally used. Valve timing, inlet pipes and carburetors were laid out with a view to the best possible operation at the full-load speed desired. Ignition systems of only the highest quality were required to furnish the necessary reliability, in view of the high speeds and continued high temperatures. Magnetos were subject to continuous heavy vibration, and must be built accordingly, while spark plugs had to meet conditions of high temperature and oil that were rarely present in automobile work. Complete oil circulation under high pressure, with special means for cooling the oil, was required to take care of the lubrication under the severe conditions imposed. At the present time, reliability of operation required complete duplicate ignition systems.

Mr. Crane concluded with a consideration of the question of aviation motors driving propellers direct and those driving them through gears. The fundamental basis of power in a gasoline motor was, of course, piston displacement. There was, therefore, always the incentive to increase the number of revolutions, with the idea of getting the greatest possible amount of power out of a given size of cylinder. We were, however, considerably limited in the possibilities of power increase by increased speed, due to the fact that the power could only be expected to increase in proportion to the speed, while the stresses in many of the parts increased as the square of the speed. Furthermore, as the life of many parts subject to repeated stresses limited the reliable life of the motor, increased speed imposed other difficulties of design.

The principal reason for gear-driven propellers was, of course, the well-known limitation of propeller design, based on the speed of the aeroplane. This limitation in aviation work was exactly similar to the limitation in motor-boat work, which had resulted in many high-speed hydroplanes having propellers geared to run at greater speeds than the driving motors. In aeroplane work, the improvement in motor design had tended to outstrip the possibilities of the propeller to such an extent that aviation-propeller speeds were uniformly lower than aviation-motor speeds, except in very-high-speed machines or in certain types of motor. This was especially true because of the military development of aviation, which naturally placed efficiency of operation ahead of long life.

The great advantage of the direct-drive machine, from the point of view of design, lay in the use of the crankshaft as a propeller shaft also, a manifest economy in material, both in the shafts themselves and in the bearings required.

All the studies that Mr. Crane had made indicated that a geared motor must weigh from 15 to 25 per cent more than a lower-speed ungeared motor of the same piston displacement. The question was whether we could get a corresponding increase in horsepower to offset the increased weight. Personally, he thought the question was still a very open one, so open, in fact, that he expected to see both types of motor continued in use for some years to come.

E. W. Roberts pointed out an error in one of the discussions, namely, that the motor should be run at the weakest mixture at which it could operate. That would result in heating the motor and blowing off the radiator.

PROFESSOR LUCKE'S REPLY

Professor Lucke, to whom the discussion was later submitted, wrote that there was practically nothing for him to say in reply except that he was pleased at the acceptance of the ideas set forth in his paper.

INDUSTRIAL SAFETY SESSION, THURSDAY MORNING

At a professional session held under the auspices of the Sub-Committee on Protection of Industrial Workers, tentative drafts of two safety codes were presented and discussed. Howard P. Fairfield acted as chairman of the meeting.

The first code, entitled Tentative Draft of a Code of Safety Standards for Industrial Ladders, included sections on definitions of ladders, general requirements for ladders, fixed ladders, portable straight ladders, extension ladders, fire ladders, portable step ladders, scaffold ladders, trolley ladders, sectional ladders, and safe practices for ladders.

This code was presented by William A. Viall and was discussed orally by Hollis P. Porter and J. G. Hatman. Written discussions were contributed by H. W. Mowery, H. M. Elder, M. W. Alexander and W. F. Wettling.

J. G. Hatman asked whether, when the Code was prepared, the Committee had consulted the work of the National Safety Council on Ladders, which had been approved by the Board of Underwriters in Chicago. Practically all the industrial plants, he said, were using that code as a standard now, and were having it approved by the Board of Underwriters.

Mr. Viall replied that all the codes he knew of followed the National Safety Council idea. In some cases it might be modified somewhat, but not to any extent.

W. F. Wettling,[1] in a written discussion, described a patented form of ladder designed to be stiff and strong enough at the weak points to overcome the danger hazard, and at the same time to be of minimum weight. This ladder was constructed with semi-tubular wrought-steel braces inserted in the recesses on the inner side of the ladder, and bent at right angles at each end and riveted to the top and bottom of each step or rung. The ladder has been approved by The Industrial Board of Pennsylvania Department of Labor and Industry.

M. W. Alexander thought that a paragraph could well be added in Section 8 under the heading Trolley Ladders, to recommend the use of a suitable locking device which would prevent a ladder from inadvertently moving under a man if, for example, he should be reaching around the side and handling a fairly heavy object. Such a locking device could be readily made and would, he believed, be an added feature in the safeguarding of such ladders.

H. W. Mowery[1] wrote that the question of safety-ladder shoes for portable ladders was one upon which there was considerable difference of opinion among those who should know. His experience had led him to the conclusion that spikes or long, sharp points on the foot of such a ladder were dangerous. The hazard of the spike was regarded as more dangerous than the hazard it was designed to eliminate.

The various types of self-adjusting shoes were, too, not entirely satisfactory. In many plants they were considered as excellent safety devices, while in other plants, equal in number and prestige, they were condemned as causing accidents.

An adjustable shoe must be kept clean, in good condition and not allowed to gum up with grease, etc., so that the abrasive, cork or other anti-slip element would be effective. That was a matter of good housekeeping, proper inspection, etc.

Decided objections were raised against such shoes on the ground that workmen seeing a ladder equipped with them would place it at any angle with the horizontal and expect the shoe to hold, thereby increasing the hazard of a fall and defeating the purpose for which the shoes were intended.

[1] The Bent Rung Ladder and Manufacturing Company, Indiana, Pa.

[1] Safety Engineer, American Abrasive Metals Co., New York.

The objection was also raised against adjustable shoes on account of increasing the weight of ladders already too heavy; but as the weight was increased 2 per cent to 5 per cent, this did not seem valid.

Until a portable ladder was so constructed that it automatically could not be used at an unsafe angle, the statistics of ladder casualties would remain about the same, with only slight reductions on account of better construction and inspection.

H. M. Elder contributed a table giving the specifications for standard ladders employed by the American Locomotive Company. He said that although their standard rung was 1¼ in. in diameter, whereas the Code specified a minimum diameter of 1½ in., they had not yet had any failure caused by weakness of the rungs. The spread at the bottom of the ladders which they employed was greater than that given in the Code.

On their work ladders got the most and severest service possible, as men were continually handling heavy material up and down them and frequently standing on them working for long periods. The safety devices used at the top and bottom of these ladders were as shown in Fig. 1.

SAFETY STANDARDS FOR POWER-TRANSMISSION MACHINERY

The second code, entitled Safety Standards for Power Transmission Machinery, contained rules and requirements for the protection of industrial workers from hazards commonly presented by mechanical equipment used for transmitting and distributing the power from the prime movers to the various power-utilizing machines, tools and devices.

This code was presented by Rufus W. Hicks and was discussed orally by Hollis P. Porter and William A. Viall. Written discussions were contributed by W. G. Ashton, C. A. Tatum and H. A. Hale, Jr. The discussion follows:

Hollis P. Porter said that he had always found the dimensions of handrails specified as being of the strength and size of 1¼-in. standard-weight pipe. A standard-weight 1¼-in. pipe had an outside diameter of 1.31 in., and he would like to know whether that was the size meant in the Code and elsewhere.

He also asked whether the specification "If constructed of structural metal the rails imposed shall be at least equal in strength to 2 x 2 x 1¼-in. angles," related to just the handrail or to the screen guards which were to protect moving parts of a machine.

In regard to belt guards, he asked what size of angle iron should be used and what relation the size of the angle iron should bear to the span which it covered between its supports.

William A. Viall replied to Mr. Porter that 1¼-in. pipe meant 1¼ in. inside diameter—ordinary commercial pipe. Replying to Mr. Porter's second question, the clause quoted was under Par. 4; everything in that paragraph applied to handrails.

Rufus W. Hicks replied to Mr. Porter's third question that it seemed to be the general practice throughout the East and in Illinois to use 1 x 1 x ⅛-in. angles for erecting guards and that these might be used in practically all cases; but owing to the fact that specifying the strength of the different structural materials was more properly the function of the laboratory, the Committee felt it was not their place to take up some special-sized angle and say that it should be adopted as the standard.

W. G. Ashton,[1] in a written discussion, drew attention to Par. 6, which calls for the construction of guards of structural metal from not less than 2 x 2 x ¼-in. angle iron. He agreed that this weight of material was necessary in a great many instances, but had found that 1¼ x 1¼ x 3-16-in. angles were sufficiently heavy in most cases. It seemed to him that the medium strength could be reduced materially, with recommendations for heavier construction where necessary. That was the policy pursued by his department, and he had found it worked out successfully, especially, at this time, when the price of structural metal had increased so much.

In Par. 7 a center rail of 1 x 4 in. was called for, and he was not thoroughly convinced that this was a practical proposition. He had been using 2 x 4-in. construction throughout, and found it more satisfactory, because 1 x 4-in., unless carefully selected, was liable to warp and did not possess the strength it should. Likewise, they had found some objection to the 4 x 4-in. post. There were places, of course, where they

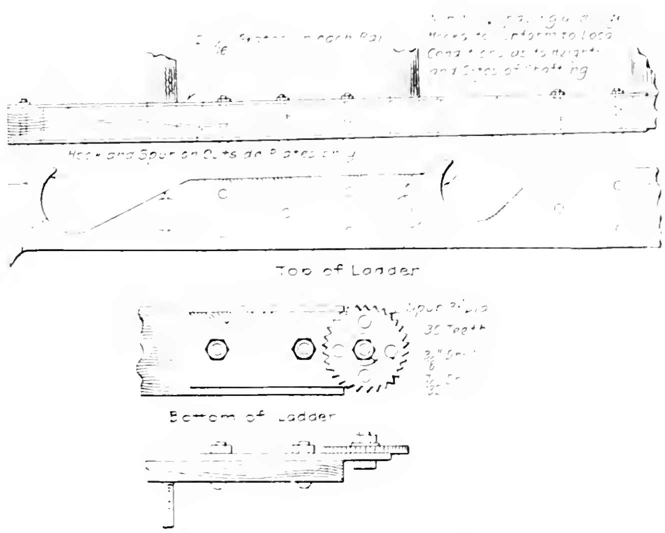

Fig. 1 Safety Devices Used on Ladders by American Locomotive Company

used it, but they applied largely the doctrine applied to the angle iron, using 2 x 4-in. construction entirely in many cases. In this connection, he suggested that the cast socket, where wood construction was used, was desirable, especially where it was necessary to remove the guard frequently. Another thing, they had found they should go more into detail, explaining that this type of construction should either be bolted together or fastened together with wooden screws. It made the guards easily removable, and when it came to durability they noticed the effect was very great.

They had found a recommendation as to the construction of angle-iron frames for guards absolutely necessary. So much of this work was squared up at the corners, oftentimes leaving a rough edge, which could be removed either by using a hack saw or an acetylene torch—the latter preferably, because the joint could then be welded, making it very substantial and doing away with the possibility of any rough edges.

In the matter of guarding the exposed sides and bottom, more especially the bottom, of high belts, particularly over passageways, many belts more than 7 ft. from the passageway were especially hazardous unless properly protected, and the notation in the Code on belts over driveways would not be

[1] Commissioner of Labor, Oklahoma City, Okla.

applicable in this case. As an illustration, a belt might be 8 ft above a runway and yet, should it break, would not only endanger life, but would endanger property as well. No hard and fast rule could be fixed on this proposition, of course, but the matter must be left largely to the judgment of an inspector. It did seem that some specific mention should be made of this particular condition, however.

The application of a guard between the belt and the pulley where the pulley was less than 30 in. from the bearing, he also regarded as inconsistent. The rule was very good where ladders were used for oiling and other work on the shaft, but he did think it could be reduced to approximately 20 in. in cases where runways were used.

In the matter of clutches, he believed that all clutches, wherever located, should be completely enclosed. The same rule should apply to them that was applied to set screws, and this same doctrine applied, in his judgment, to a majority of couplings.

The one problem that they had to contend with was the matter of protecting horizontal shafting. A condition in

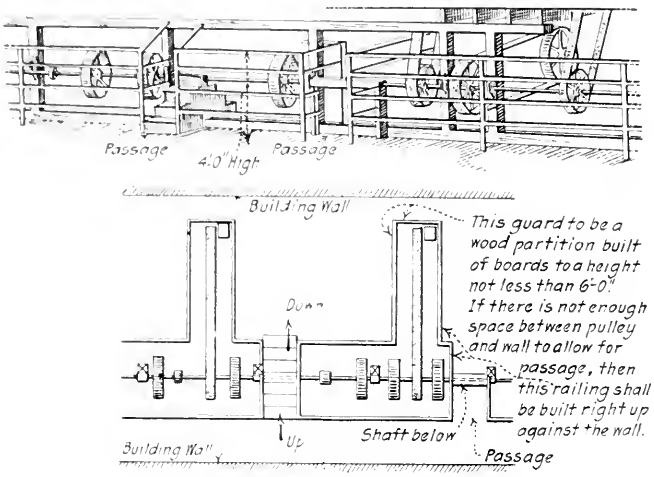

FIG. 1 GUARDS FOR GIN LINESHAFT

cotton oil mills and gins made it almost impossible to apply standard guards as specified under Classes A and B, and handrails must be relied upon to eliminate the hazard. In a cotton gin, for instance, the lineshaft would be in the basement and approximately 40 ft. long, with some 12 or 14 pulleys, averaging about 30 in. in size. The pulleys would all be equipped with idlers, and to place a handrail with a standard clearance of 5 in. from points of contact would make it impossible for the oiler to get to the bearings from the outside of the fence; likewise, belting one of the pulleys through a fence of 15 in. would be a very cumbersome job.

The common thing had been to put a gate at the edge of the fence or handrail, and the oiler, and others who had some operation to perform along the shafting, went down between the handrail and the moving parts. In fact, the belting was done from there and in many cases there was a tendency to crawl through the handrail and go under or over the shaft as the case might be.

Experiment with this proposition had shown that the belting and the oiling could be done from outside the guard, provided it was placed about 8 in. from the points of contact of the pulley. In fact, the gin men and the oil-mill men said that they belted with more ease following this method. To overcome the feature of crawling through the fence, it had been constructed 48 in. high, and made with four rails instead of two. Through this operation, all the serious accidents that had been occurring in the State in years past had been eliminated.

Argument had been advanced that this guard could be built around the pulleys, but too much care could not be taken about constructing as little of this mechanism around the shafting as possible. For this reason, they did not like the idea of building around each individual pulley; then, too, this reason did not apply in the case of overhead runways, and it seemed inconsistent to require it on ground-floor shafting. Fig. 1 showed their method of guarding a gin lineshaft. At the passageways the guard had to be closed up where the pulley was closer than 15 in.

He thought it would be beneficial to specify the weights and grade of filler to be used. Employers invariably allowed their economy ideas to prevail, with the result that galvanized wire mesh and things of that kind of very little weight were used. This has had a disastrous effect, because of lack of durability, damaged parts causing raw edges. They were now specifying 18 gage steelcrete with ½-in. mesh, or 13 gage with ¾-in. mesh, or diamond wire mesh of these weights and sizes, with very good results.

Specifications along construction lines should be incorporated in the specifications in Class A and B guards. Employers should be cautioned to construct the guards so as to leave the bearings outside the guard, and where this was impossible, the bearings should be tapped and equipped with extension oilers, extending outside the guard. Again, special caution should be given that where these close guards were made, doors full length of the guard, allowing the employees access when necessary to make repairs, should be provided. To further carry out this idea of repairs, where it was necessary floor sockets should be provided so as to make the guards easily removable. These sockets should be not less than 16 in. deep, with ¼-in. walls and a 3½-in. base ⅜ in. thick. On this point, in dealing with food-producing establishments, stress should be laid upon the necessity of leaving one side of this socket open so as to afford cleanliness. Also it should be specified that the filler, where used on 1¼-in. standard pipe should be constructed on an independent frame of not less than 1-in. channel iron secured to the iron pipe in a substantial manner.

A thing that seemed to have been overlooked in the specifications was a standard upright guard in front of high-speed belts at passageways, and this applied particularly at floor passageways. They had used two types of guard for protecting this, one type being iron pipe of various dimensions, setting it in concrete in the floor and extending it to the ceiling or supporting it from the wall back of the guard. Another was to use angle-iron frames filled in with very heavy sheet metal or boiler iron. In one plant the generator belts were protected with 4-in. iron pipe set in 3 ft. of concrete, using five pipes in front of each belt. These belts broke frequently, and the guard served as a perfect protection. In other places of lighter belts of less speed, they were using the angle-iron frames.

C. A. Tatum[1] wrote that it was important that standards be defined on conditions effecting the safety of machine operation, and also for the purpose of arriving at a fixed basis or practice for insurance purposes as well.

The matter of friction drives had also been overlooked in the Code. They were using a complete enclosure for this

[1] Manager, Safety Department, Texas Employers' Insurance Association.

type of drive, made on a frame of $1\frac{1}{4}$ x $1\frac{1}{4}$ x 3-16-in. angle filled in with 18-gage ½-in.-mesh expanded metal, or 20-gage sheet metal. This was the general type of guard. In other cases they were using a band guard of cast iron extending clear around the friction and flanged down on both sides beyond the points of contact. They were using 16-gage metal in most cases, reinforced with ½-in. strap iron.

Another thing they had found almost imperative was that solid enclosures for couplings, dead-shaft ends and things of that kind should be independently supported so as not to revolve with the moving parts. Where these guards were so constructed that they revolved with the moving parts, they created a hazard in themselves.

Referring to Par. 11, the insurance rating schedule took no consideration of the speed of the belts, charging for a 2-in. hack-saw drive the same as a 42-in. counter at 7000 ft. per min. and making the same requirement in each case. Belts over a certain weight and speed could not be protected by the ordinary guard from the dangers incident to breaking, but this danger would rather be increased in the event of a break by the presence of either woodwork or fabricated steel used as a guard; and it was his opinion in cases of this nature that the standard handrails, properly located, should be employed instead of trough guards or housings. A condition prevailed in the South in cottonseed-oil mills, of which there were a large number, where the drive of the attrition mill using two 8-in. belts to disks moving opposite it, required 8-in. belts at about 7000 ft. speed, and in which the most practical method of protection would be to use the hand rails shown in Fig. 44, of the proposed Code. The trough guards or a solid enclosure would increase the hazard on account of the necessity of a number of employees always being engaged in the vicinity of the machine.

With regard to Par. 29, set screws employed to secure pulleys could not be of the safety type, and it was necessary that exceptions be made in cases of this kind; but it should be required that a cover be used, which might be either of a turned wooden block properly secured, or a leather strip wound around the hub to the height of the screw, and made secure.

Referring to Par. 39, an effective signal system should be required in all plants where machinery was in group drive, and fixed rules should be established for the use of these signals. Negligence on this point had caused a large percentage of the serious accidents in the industries. The compensation rating schedule took no cognizance of a signal system, but it was his opinion that in many plants the importance of a well-laid-out signal system, with defined rules of operation, was such that it would be entitled to a substantial credit on the plant. It should carry about the same value as the stop-and-start device or ten-machine limit on group drives. Par. 34, should be a companion charge or credit, with a stop-and-start device on machinery.

Par. 40 dealt with an important feature in any plant, and it should be made requisite that the same record of inspection of improvements be kept on transmissions as on the individual machines.

Henry A. Hale, Jr.,[1] recommended the following changes in the Code to make it harmonious with the safety standards now recognized by practically all companies writing workmen's compensation and liability insurance throughout the United States:

Par. 2, Line 2, to read: "Guarded part is less than 4 in., etc.," the assumption being that a person's finger cannot project more than 4 in. and become injured, through a substantial guard that will not admit objects larger than 2 in.

Par. 3, Line 2, to read: "Guarded part is 4 in. or more, etc.," this change being explained as above.

Par. 4, Line 3, to read: "Extreme parts within 6 ft. of floor, a handrail 36 in. in height," this standard being recognized by the insurance companies as affording adequate protection.

Par. 4, Line 5, to read: "Supported at least every 8 ft., of substantial and rigid construction, with no sharp points or edges." With this definition it appeared that Pars. 5, 6 and 7 were entirely superfluous. The dimensions mentioned in these paragraphs did not contribute to the effectiveness of the guard unless the work of construction and erection was properly executed. The dimensions of materials used should therefore be left to the discretion of the one who designed or erected the railing.

Pars. 9, 11, 12, 13, 14 and 15 to be supplemented by the following:

"Belts (chain, rope) shall be completely enclosed or effectively guarded. Guards shall be of substantial construction, securely fastened in place and of such size and arrangement that a hand or other part of the body cannot project through, over, around or underneath guard, and be caught at point of contact of belt and pulley, or between spokes and pulley and adjacent framework or other fixed part.

"If the point of contact of belt and pulley is within 6 ft. of floor or platform level, a guard shall be provided, the top edge of which, if higher than the point of contact, shall not be less than 15 in. from such point of contact,[2] but in no case need the guard be higher than 6 ft. from floor or platform, nor shall it be less than 36 in. in height.

"If the top edge of guard is lower than the point of contact of belt and pulley located within 6 ft. of floor or platform shall be considered as standard if consisting of a double railing 36 in. in height.

"If the point of contact of a vertical and inclined belt and pulley is more than 6 ft. above the floor or platform, guard shall be 36 in. in height with the top edge not less than 3 in. nor more than 15 in. (measured horizontally) from the vertical projection of all portions of the belt and pulley within 6 ft. of floor or platform level.

"Where pulleys are of such dimensions and so located as to permit passage between upper and lower part of belt, standard railing shall be provided and a substantial passageway, guarded on sides and top, shall be constructed, or space, traversed by belt, shall be completely barred against passage.

"Overhead belts, with lower part 7 ft. or less from floor or platform level, shall be guarded on sides and bottom, or space underneath belts to be railed off to avoid use for passageway or storage."

It was inadvisable to use a railing for a guard in connection with rope transmission, except in some cases along the sides of a horizontal drive, as in many instances a broken rope had become entangled in a railing guard, causing considerable havoc.

In Par. 11 an exception was provided to the effect that guards were not required on belts "transmitting so little power that accidental contact therewith could cause no accident." This vague expression was very misleading, for he could not conceive of any equipment that would come under

[1] America Mutual Liability Insurance Co., Boston, Mass.

[2] It is undesirable to locate a guard more than 15 in. (measured horizontally) from a moving part and thereby permit persons to get between the guard and danger point.

this category. For example, a 5/8-in. diameter belt on a sewing machine had caused an injury to a female employee costing the insurance carrier $9,000 to settle. While he would not recommend that all 5/8-in. belts should be guarded, yet some definite width or diameter of belt should be expressly mentioned as a minimum where guarding was required.

In Par. 10, if the floor of a wagon was to be considered as a working platform, were we not permitting a railing on wagon floor to serve as a guard in accordance with Par. 15?

Pars. 24, 25, 26 and 27, Mr. Hale recommended, should be replaced by the following substitute: "All couplings within 7 ft. of the floor or working platform or within 36 in. of a bearing shall be concentric with the shafting and guarded as follows: Dangerous projections shall be completely enclosed or guarded in such a manner as will prevent the clothing of persons from being caught thereon."

In Par. 31, Line 2, the words "to stop immediately all power-transmission equipment" were objectionable, and as a substitute the following was recommended: "To disengage the power driving all engine-stop systems." To his knowledge there was no means of stopping all the power-transmission equipment "immediately" or "instantly" without inflicting considerable damage. Reference to "locking in stop position" should be confined to clutches and tight- and loose-pulley equipment.

Par. 41 permitted removal of guards for repairs and adjustments, while Par. 42 stated that guards should not be removed. This inconsistency should be corrected.

In conclusion, he recommended that action in adopting any code of standards for power-transmission machinery should be deferred at this time. There was an urgent need of harmonizing so far as possible, the code that might be adopted by the Society with other standard codes now in force, and it would appear that ample deliberation in this connection would tend to eliminate unnecessary waste and confusion by giving a little more time for careful consideration of the draft submitted.

CORRESPONDENCE

CONTRIBUTIONS to the Correspondence Departments of The Journal by members of The American Society of Mechanical Engineers are solicited by the Publication Committee. Contributions particularly welcomed are suggestions on Society Affairs, discussions of papers published in The Journal, or brief articles of current interest to mechanical engineers.

Strength of Boiler Furnaces

To the Editor:

In reply to Mr. H. J. Vander Eb's comments published in the February, 1917, issue of The Journal upon my communication on the Strength of Boiler Furnaces which appeared in the October, 1916, issue, the point I wished to bring out was the undesirability of a lap joint, and my discussion was leveled at the A.S.M.E. Boiler Code rule only, inasmuch as it permits a lap joint. I would like to see some criticism of the theory I suggested in the August, 1916, issue of the Journal of the American Society of Naval Engineers, on page 729, because, failing that, I maintain that a lap joint in a cylinder subjected to external pressure is far weaker than it has been hitherto supposed to be, and therefore all rules permitting it are bad. Interest centers round the A.S.M.E. Boiler Code rule as being probably the most influential one in the future.

Regarding the points raised by Mr. Vander Eb:

1 *Fairbairn's Rule.* This was taken because of its interest as the parent formula. It is customary to consider this as applying to jointless flues (if used at all). A careful perusal of Fairbairn's original paper prohibits its use for a lap joint. It is true Fairbairn used joints brazed and riveted, but it is equally sure that he regarded them as very different from a conventional lap joint. They were probably spliced joints and carefully brought to a true circle. As proof of this, note that Experiment 23 was an *ordinary* lap joint and that Experiment 4 was a single-strap butt joint. The relative strengths of these two joints were in the ratio 69.3 : 100.

In using results for the calculation of constant in formula, *Experiment 23 is ignored but 24 is taken.* Apart from this convincing fact, the phraseology often shows Fairbairn's clear conception of the importance of circularity.

I agree with Mr. Vander Eb's criticism of Fairbairn's formula. I think this is generally admitted.

2 *Hutton's Rule.* As this rule is closely allied to Fairbairn's, it is presumably intended for jointless flues (or truly circular flues, which are nearly equivalent), pending more definite evidence to the contrary. The fact that it is sometimes used for lap-jointed flues simply results in a smaller factor of safety than is supposed to exist.

3 Regarding the supposed unfavorable dimensions of the particular concrete case I took, it was the failure of this actual flue, due to buckling just outside the lap joint, that caused me to investigate the action of the joint analytically and, incidentally, to compare a few formulæ.

4 My application of the German Government rule was incorrect. I accept Mr. Vander Eb's correction.

5 I have never found any authority for using Lloyd's rule on lap-jointed flues. The fact that this is done in some instances merely goes to show the need of definite regulations in the matter to prevent appropriation of part of factor of safety.

6 *Board of Trade Rule.* I regret omitting to increase the constant by 10 per cent to allow for steel instead of wrought iron. This, however, will not check with Mr. Vander Eb's figure. My allowing for a single-riveted lap joint was quite correct, as the constant I took was for a double-riveted joint, which necessitated a reduction in the ratio of the supposed efficiencies. The several sources of information I consulted did not give a constant for a single-riveted lap joint.

7 The fact that Boiler Code rule takes into account the full length of the flue instead of separate sections, as some formulæ do, is admittedly in its favor where such conditions exist. Where such conditions do not exist it is rather pointless to argue what would happen if they did exist. Ultraconservatism under one set of conditions is no offset for shortcomings under other conditions.

I wish again to emphasize the weakness of a lap joint. I believe all formulæ which permit lap joints result in giving a much smaller factor of safety than is commonly supposed. I should very much like to see a discussion on the theory I

suggest, as hitherto we have looked upon the action in a lap joint as somewhat obscure from an analytical standpoint and not lending itself to definite analysis.

Until a fallacy in my theory is found I hold the opinion that a lap joint is capable of being analyzed, or at least that we can figure a certain condition that the actual state of affairs is equal to or worse. Moreover, this condition is surprisingly bad.

It is important to note that where a formula does not permit of a lap joint, and an adjustment is made according to the conventional theory for lap joints, as was done in the first part of my A.S.M.E. paper, the results are very questionable. The absurdity of the orthodox theory is grasped when it is considered that if the rivets fill the holes perfectly the efficiency will come close to 100 per cent when the joint is in compression. Actually I have shown that the joint proper may be left almost out of the question, as the weak spot is just where lapping begins. This is a well-known fact experimentally, as the double thickness of the plate remains intact, the buckling occurring just where this leaves off.

JOHN AIREY.

Chicago, Ill.

WORK OF THE BOILER CODE COMMITTEE

THE Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York City.

The procedure of the Committee in handling the cases is as follows: All inquiries must be in written form before they are accepted for consideration. Copies are sent by the Secretary of the Committee to all of the members of the Committee. The interpretation, in the form of a reply, is then prepared by the Committee and passed upon at a regular meeting of the Committee. This interpretation is later submitted to the Council of the Society for approval, after which it is issued to the inquirer and simultaneously published in THE JOURNAL, in order that anyone interested may readily secure the latest information concerning the interpretation.

Below are given the interpretations of the Committee as approved by the Council on April 19-20, 1917, in Cases Nos. 146 to 152 inclusive. In this report, as previously, the names of inquirers have been omitted.

CASE NO. 146

Inquiry: Is it necessary under the requirements of the Boiler Code that pressed steel manhole plates shall be stamped as to the quality of the steel, heat number and tensile strength provided they are ordered flange or firebox steel?

Reply: The rules of the Boiler Code do not specify that pressed steel used for manhole plates should be stamped. The plates to be so stamped are specified in Par. 36 of the Code.

CASE NO. 147

Inquiry: What is the correct location for the bottom gage cock in a vertical tubular boiler? One-third the length of the tubes above the top of the lower tube sheet is found to be too short for short tubes and too long for long tubes.

Reply: It is the opinion of the Committee that this inquiry is answered by Case No. 86. In the revised Code the fusible plug limits given in Par. 430 of the Boiler Code will be estalished as the lowest permissible water levels for the various types of boilers.

CASE NO. 148

Inquiry: Will the design of steel handhole cap for use in water tube boilers of the waterleg type, shown in Fig. 7, meet with the approval of the Boiler Code Committee? This cap requires no gasket to make it tight, being inserted in the hole from the inside of the waterleg and expanded from the outside with a special expanding tool, which is also used for the purpose of truing up the holes, making them standard size and slightly tapering from the inside outward.

Reply: The Committee has decided that it will not express approval of any specific construction. Attention is called to the fact that a device of the sort should meet the requirements of Par. 251 which calls for the ends of all tubes, suspension tubes and nipples when not beaded to be flared not less than 1/8 in. over the diameter of the tube hole on all water tube boilers and superheaters, this flare in the present instance to be on the pressure side of the plate. If the requirements of this paragraph are met, there is nothing in the Code to prevent the use of the design, provided the material from which it is constructed meets the requirements in Par. 5.

CASE NO. 149

Inquiry: Will the arrangement of equalizer pipe for double drum water tube boilers, shown in Fig. 8, meet with the approval of the Boiler Code Committee for working pressures up to 225 lb.? The equalizer is to be made of extra heavy cast iron flanges, the joints in the pipes to be welded.

Reply: It is the opinion of the Committee that this design will not be permissible under Par. 277 of the Code.

CASE NO. 151

Inquiry: Are cast iron dovetail or slip lugs permitted under the rules of the A.S.M.E. Boiler Code for horizontal return tubular boilers?

Reply: It is the opinion of the Boiler Code Committee that there is nothing in the Code to prevent the use of this type of bracket, provided it is properly designed and conforms to Pars. 323, 324, and 325, and is used only where cast iron brackets are allowed.

CASE NO. 152

Inquiry: Is it necessary that safety valves for use on industrial steam locomotives, that are not subject to federal inspection or control, shall, if constructed to meet the requirements of the A.S.M.E. Boiler Code, be fitted with the lever specified in Par. 282? It would appear advisable to make the use of the lever optional inasmuch as 70 or 80 per cent of the railroad locomotives in the United States are using safety valves without levers.

Reply: If the safety valves referred to are to be applied to boilers that are to be constructed and inspected under the Boiler Code, it will be necessary to apply the levers and in all other respects conform to the requirements of the Code.

Progress of the Code

Members will be interested to know what progress the Boiler Code has made in the various states, and the following are excerpts from a report made by Mr. Thomas E. Durban.

chairman of the administrative council of The American Uniform Boiler Law Society, on that question.

NEW YORK

The Code Committee of New York has formally adopted the A.S.M.E. Code and reported it favorably to the Industrial Commission. The Commission consists of the following: John Mitchell, Chairman; Edward P. Lyon, Louis Wiard, James M. Lynch, and Henry D. Sayer. A great deal of the work has been done by Thomas C. Eipper, Deputy Commissioner, and chairman of the Committee on Boilers.

Probably no state will give the matter of the Boiler Code greater care than did the State of New York. The Code Commission went up and down through the state, and then published a tentative code, and went up and down the state again, getting criticisms and comments on this code, pursuing much the same course that the Boiler Code Committee of The American Society of Mechanical Engineers pursued in its original work, but gave the public greater chance, perhaps, to criticize and make suggestions than has ever before been accorded. Meetings were held in Buffalo, Syracuse, Rochester, Utica, Albany and New York, and much interest was developed and much valuable information obtained. It is a great compliment to our Committee that, after all this strenuous work, the A.S.M.E. Code was adopted verbatim.

We have just been advised by the State Industrial Commission of New York that the Commission, at a meeting held June 5, 1917, adopted the proposed rules for boilers in factories in the State of New York, as formulated by their Advisory Committee, effective July 1, 1917, new construction, effective January 1, 1918.

MICHIGAN

An enabling act was passed unanimously by the house and senate, and has been signed by the governor, and a committee will be appointed to proceed with the adoption of the Code.

In all the effort made, the understanding has been that the A.S.M.E. Code would be adopted. It is reported that the Code will not be placed in effect till early next year.

Great assistance has been rendered by Mr. J. C. McCabe, Chief Inspector of Steam Boilers of the City of Detroit; Professor M. E. Cooley, of the University of Michigan; Professor Bissell, of Lansing; Mr. E. C. Fisher, of Saginaw; and Mr. T. H. Hinchman, of Detroit.

NEW JERSEY

An enabling act was passed by the legislature and signed by the governor, the same as in Michigan, and it is understood that in due time New Jersey will issue the Code and announce the date of its going into effect.

The Code will be put into operation under the jurisdiction of Colonel Lewis T. Bryant, Commissioner of Labor. A Board of Boiler Rules has been appointed which consists of three inspectors, Messrs. Case, Scott, and Walker, and two appointees from the community at large: F. W. Casler, Mem. Am.Soc.M.E., representing the boiler users, and Frank Van Winkle, representing the boiler operators.

MINNESOTA

Minnesota has issued a notice through the duly appointed representatives of the Inspection Board of the state, that on and after January 1, 1918, all boilers must be made according to the A.S.M.E. Code. This has been approved by the governor, and renders the Code absolutely effective after the date mentioned.

Much of the credit for the accomplishment of this is due to Mr. Max Toltz and Mr. Oliver Crosby, of St. Paul.

MISSOURI

The City of St. Louis has passed the Code to put it in operation, as has also Kansas City, and it is understood that the City of St. Joseph is contemplating similar action. With the example set by these cities, at the next meeting of the legislature the Code will probably be adopted by the State of Missouri.

COLORADO

The new Industrial Commission of the state will probably have the power to adopt the Code, and the Boiler-Law Society is in correspondence with the Commission at this time.

CANADA

The Province of Manitoba is revising its boiler code, and expects to call a meeting in the near future with the idea of getting the coöperation of the other provinces in Canada, in the hope that a universal rule can be made for Canada. The Boiler-Law Society is in correspondence with the various provinces, and there has been expressed a desire to make the A.S.M.E. Code operative in Canada. In this the Society has the strong support of the Province of Ontario, which is one of the leading provinces in Canada, and also of the leading boiler manufacturers throughout the entire Dominion.

SUMMARY

The states and cities in which the Code has been adopted or is in process of adoption are:

New York	Indiana
New Jersey	Michigan
Pennsylvania	Wisconsin
Ohio	Minnesota

California

Kansas City and St. Louis, Missouri

Respectfully submitted,

(*Signed*) THOS. E. DURBAN,
Chairman.

An American Committee of Engineers has been formed in London which will be glad, among other duties, to give assistance to any American engineers arriving in England on any official business connected with the War. This assistance would probably take the form of offering advice and hints as to saving time in approaching British official departments.

The address of the committee is 6 Copthall Avenue, London, E. C., and the Hon. Secretary is Mr. C. W. Purington.

A memorial fountain has been erected in the old engineering building of Tulane University, in honor of Prof. Henry F. Rugan, associate professor of mechanical arts at the University at the time of his death, September 3, 1916. Mr. L. W. Zeller made the presentation speech on behalf of the students, and Prof. W. H. Creighton, dean of the College of Technology of Tulane University, in accepting, praised the research work on the growth of cast iron by Professor Rugan.
